Disclosure of Risk Information in the European Banking Sector

JEL Classification: *E44; E52; E58; F33; G18; G21; G28*

Keywords: *risk disclosures; financial statements; accounting standards; GAAP; IFRS*

Abstract: The debate on the scope of bank information disclosures seems to be an essential issue, especially after the 2007-2010 financial crisis. The adequate number of data provided to the public domain is the condition of transparency of the banking sector, which should assure the optimization of market participants' decisions. There is also a tendency to unify the global accountancy standards and they are expected to ensure the same scope of disclosed information for the global financial market. The aim of the study is to check if the accounting standards required by the European countries influence the number of risk disclosures and if more stable banking sectors tend to report wider scope of data. Finding out the nature of disclosures' determinants is an important aspect in terms of working out the procedures increasing the transparency and stability of the financial markets.

Introduction

For the sake of the specific role that the banking sector plays in the economy, there are applied strict disclosure requirements in relation to financial institutions. A wide range of disclosures required by banking authorities is due taking care of to not only the interests of the stakeholders, but also the stability and security of the financial system.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

The turbulences in the financial markets are real threat to the entire economy because of the occurrence of the so-called contagion effect. Therefore it is important to introduce the early warning systems based on the ongoing monitoring of the banking sector and providing data analysis of the risks arising from the activities of banks and external conditions.

The proper functioning of early warning systems is subject to access to information about the various risks associated with the operations of financial institutions. Thus, the role of transparency and fulfilling the information requirements is often emphasized as the key issue in this sector. The relevance of disclosures was intensively discussed after the 2007 financial crisis, especially the risk and corporate governance data that appear to be essential when the banks transparency is concerned. It is important to notice that the quality and quantity of disclosures is directly related to the quality of corporate governance. This fact is emphasized, for example, by Bhimani (2009, pp. 2-5), Power (2009, pp. 849-855) and Harney (2010, pp. 14 – 17) in their research regarding risk accounting.

This paper examines the nature of risk disclosures of European banks with special consideration of the risks data required under International Financial Reporting Standards (IFRS) and local Generally Accepted Accounting Principles (GAAP). The article presents arguments supporting the importance of disclosures in the financial system. Then there will be characterized the various kinds of risks in banking sector and the reporting requirements resulting from the application of different accounting standards. Finally the author will present the results of research based on data submitted by banks in accordance with the COREP standard, which is a technical reporting instrument designed to harmonize reporting in accordance with the Capital Requirements Directive (CRD).

Methodology of the research

The aim of the study is to find out if the number of disclosed risk data depends on the applied accountancy standards. The author will also check whether more stable bank sectors tend to disclose wider scope of risk information.

The database which is the subject of analysis has been developed on the basis on the information published on the website of the European Banking Authority (European Banking Authority, EBA) - publication date: 10/03/2010,last updated: 02/18/2014 - and the data from the database SNL Financial. It includes aggregated information about 30 European banking

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

markets regarding the range of disclosures of the capital adequacy, values of own funds established for the purposes of calculating the capital adequacy ratio, capital requirements for particular risks and data on the values of exposure subject to various risks, with taking into account the risk mitigation methods.

The database has been supplemented with qualitative variables, ie. the value of risk-weighted assets (RWA) and capital adequacy ratios (CAR) of each country capital sector (aggregated data). Asset value usually determines the size of the banking sector, while CAR may be considered as a measure of banking system stability.

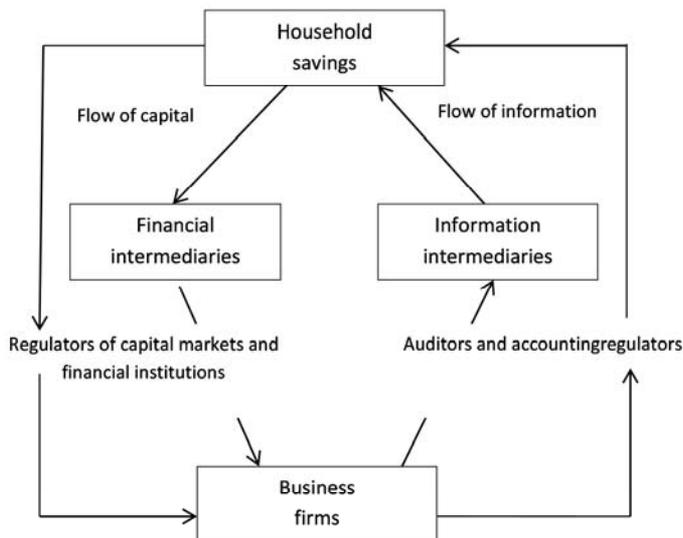

The author used the SPSS software package to evaluate the above mentioned issues. The influence of accounting standards on the number of disclosures was assessed with the analysis of variance (Welch and Brown-Forsythe tests). To simplify the calculation the author constructed the disclosure index and confirmed its reliability with the Cronbach's alpha coefficient. There was also used the linear regression analysis to check if the scope of the disclosures depends on the bank sector stability.

The importance of disclosures in the financial statements

The objective of financial statement is to provide information about the financial position, financial performance and cash flows of an entity that could be useful to a wide range of market participants in making economic decisions (Świdarska, 2010, p.15). In addition, it proves the managers' diligence in managing the entrusted to them resources and thereby reduces the information differences and conflicting incentives between entrepreneurs and savers (Healy, Palepu, 2001, p.407).

The problem of asymmetric information may be solved with the high transparency of managers' decisions and activities. The transparency and honesty of information is expected to be guaranteed by the capital markets intermediaries, such as financial analysts and rating agencies. Figure 1 provides a scheme of flow of capital (left side) and flow of information (right side) within the capital markets.

Figure 4. Financial and capital flow in the capital markets

Source: Healy, Palepu (2001, p. 407).

As it is shown at the scheme, the investor is not an identical entity as the entrepreneur. That implies the existence of so called agency problem, which is a result of unbundling of ownership and management. Savers usually do not intend to engage in managing and delegate all the business decisions to their agents (managers) responsible for taking care of the proper dealing with the entrusted capital. It may cause two major kinds of conflicts - insufficient managers' motivation to look for the business opportunities and the 'moral hazard' meaning the inventiveness to put the interest of managers instead of company first.

One of the possible solutions reducing the agency problem is the disclosure policy providing market participants with the adequate data that enable to monitor and make up decisions and actions involving:

- buying, maintaining or selling the securities,
- assessing the efficiency of management,
- assessing the company's ability to pay wages and other employee benefits,
- assessing the quality of collaterals and loans,
- evaluating the tax policy,

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

- determining the proportions of profit-sharing and dividends,
- preparing statistic data regarding the GDP,
- regulating the business activities (Świdarska, 2010, p.15).

Types of risk in the banking sector

Providing the financial services by banks implies the existence of various kinds of risk that should be carefully recognized and analyzed. The proper risk measurement and management seem to be the most important issues when the functioning of financial institution is concerned. Table 1 presents the risk characteristics specified by Santomero (1997), Pyle (1997) and Frenzel et al (2011).

Table 1. Types of banking risk characterization

Type of risk	Santomero	Pyle	Frenzel et al.
Market risk	See: systematic risk	the change in net asset value due to changes in underlying economic factors such as interest rates, exchange rates, and equity and commodity prices	The volatility of the fair value of the financial instruments or the future cash flows due to changes of the market prices.
Credit risk	Risk arising from either an inability or an unwillingness of a borrower to perform in the pre-committed contracted manner.	The change in net asset value due to changes the perceived ability of counterparties to meet their contractual obligations.	The risk of loss resulting from the inability to fulfil the contractual obligations by the counterparty.
Operational risk	Risk associated with the problems of accurately processing, settling, and taking or making delivery on trades in exchange for cash. It also arises in record keeping, processing system failures and compliance with various regulations.	Risk resulting from costs incurred through mistakes made in carrying out transactions such as settlement failures, failures to meet regulatory requirements, and untimely collections.	-
Performance risk	-	Risk encompassing losses resulting from the failure to properly monitor employees or to use appropriate	-

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

		methods (including "model risk").	
Systematic risk	The risk of asset value change associated with systematic factors. It is sometimes referred to as market risk.	-	-
Counterparty risk	Risk coming from non-performance of a trading partner. The non-performance may arise from a counterparty's refusal to perform due to an adverse price movement caused by systematic factors, or from some other political or legal constraint that was not anticipated by the principals.	-	-
Liquidity risk	The risk of a funding crisis.	-	The risk of inability of the bank to fulfil its obligations.
Legal risk	Risk endemic in financial contracting and separate from the legal ramifications of credit, counterparty, and operational risks. These are new statutes, tax legislation, court opinions and regulations as well as fraud, violations of regulations or laws.	-	-

Source: Self study.

Most of the above mentioned risks could be recognized and properly managed only on condition that the corporate governance processes are well-defined and implemented. They guarantee the transparency of bank operation and mitigate the agency conflict, which could lead to underestimating or hiding the risk to stakeholders in order to enable some moral hazard actions. There should be noticed, however, that several kinds of risk are hard or even impossible to predict and measure. These are for example systematic, counterparty and legal risk which mostly depend on the external

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

circumstances. The other risk factors are usually identifiable if two preconditions are performed – the full disclosure and proper measurement.

Risk disclosures literature review

The risk disclosure research has been initiated with the studies performed by the Institute of Chartered Accountants in England and Wales (ICAEW, 1997) and the Basel Committee on Banking Supervision (BCBS, 1998). They discussed a role of transparency and risk information that should be included in the financial reports or other additional documents released by the companies. A kind of theoretical debate, based on BCBS survey was presented by the Linsley and Shrives (2005, pp. 205-214) who collated the risk disclosure requirements with the bank reporting practices.

Linsley and Shrives (2005, pp. 292-295) conducted also a research taking into account UK public companies listed in the FTSE 100. Their study found that in most entities the risk disclosures are not quantitative but qualitative. Similar conclusion was driven by Lajili and Zeghal (2005, pp. 125-142), who analyzed 300 listed Canadian companies stating that the usefulness of reported risk information is limited by the lack uniformity, clarity and quantification. This is consistent with the Woods, Dowd and Humphrey's (2004) statement that the institutions "want to signal that they have state-of-the-art (or at least adequate) risk management systems, but they don't want to give real risk information away, as such information is commercially sensitive. Thus, 'risk disclosure' might be more apparent than real".

Presently, a great number of studies use the disclosure indexes that may be treated as an important information about the quality of corporate governance practices. Their construction involves on gathering answers to the questions if specific company data is disclosed to the market.

Brazilian Corporate Disclosure Index built by Lopes and de Alencar (2008) is based on the answers to 47 questions relating to the general information about the company, compensation policy, non-financial market data, sales, cash flow and earnings forecast, financial and other data analysis. Cheung, Connely and Limpaphayon (2007, pp. 313-342) used the information about disclosures for the construction of disclosure index for Thailand and Hong Kong. It includes the "poor/fair/excellent" answers regarding the disclosures of stakeholders' rights protection, equality of investors' treatment, the role of stakeholders in corporate governance practices, company's transparency and the role of board of directors. Lopes and

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

Rodrigues (2007, pp.25-56) used the financial instruments disclosure index as a dependent variable trying to evaluate the disclosure determinants in Portugal. They analyzed 54 elements regarding the information on accountancy policy, fair and market values, securitization, derivatives, interest rate risk, credit risk, collaterals and others. Cheung, Jiang and Tan (2010, pp. 259-280) presented the disclosure measures divided to the obligatory and facultative ones in terms of the reporting practices of the largest publicly traded Chinese companies. There also exists the Polish Corporate Disclosure Index (Świdorska, 2010) which is a weighted average of disclosures taken from the company's financial statement (66%), operating statement (24%) and the report of relationship with the business environment (10%).

Disclosure requirements according to GAAP and IFRS

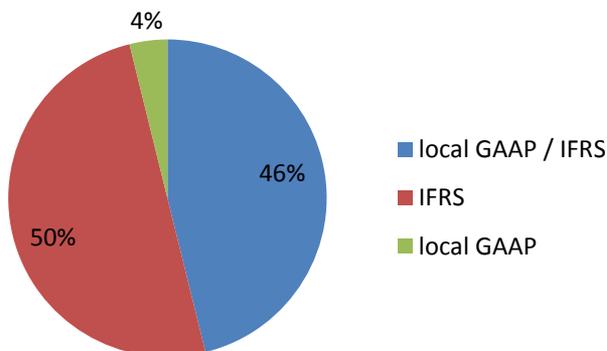

In the late 1990s companies in several EU member states were allowed to voluntarily apply International Financial Reporting Standards rather than local Generally Accepted Accounting Principles. Presently, however, after 1st January 2005, the International Accounting Standards (IAS) regulation requires publicly traded companies to present consolidated financial statements in conformity with IFRS adopted by the European Union (IFRS-EU) for each financial year. Member states may permit companies to defer the application of IFRS-EU when:

- only their debt securities are admitted to trading on a regulated market of any member state; or
- their securities are admitted to public trading in a non-member state and, for that purpose, they have been using internationally accepted standards since a financial year that started prior to 11 September 2002 (for this purpose, internationally accepted standards are generally understood to include only US GAAP).

In practice, the IAS Regulation allows jurisdictions to prohibit any specific type of company from using IFRS in their legal entity financial statements, and, in the case of non-publicly traded companies, their consolidated financial statements (Financial Reporting Faculty, 2007, p.19). Thus, only a part of European countries apply IFRS to all bank entities, most of them allow using both IFRS and local GAAP regulations (see: Figure 2).

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

Figure 2. The accountancy standards requirements (European banks)

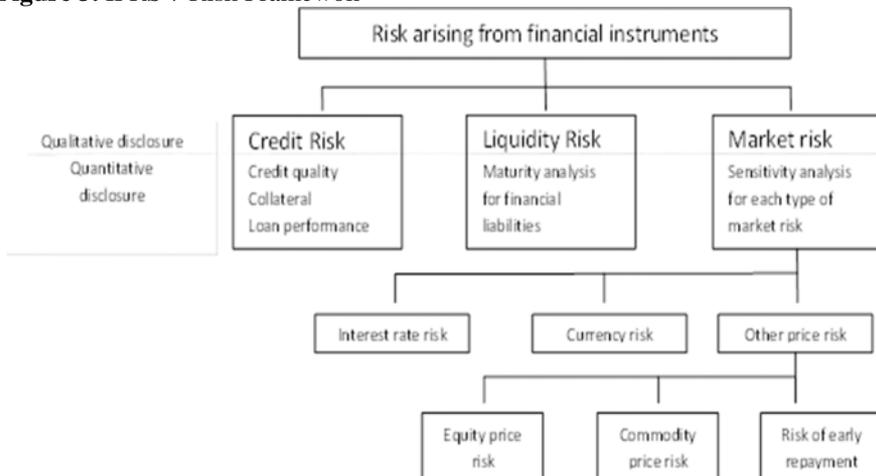

Source: own calculations based on COREP statistics

According to the IFRS 7 - the standard relating to financial instruments disclosures - entities should disclose both qualitative and quantitative data concerning the market risk, credit risk and liquidity risk (see: Figure 3). The objective of IFRS 7 is “to require entities to provide disclosures in their financial statements, that enable users to evaluate (1) the significance of financial instruments for the entity’s financial position and performance; and (2) the nature and extent of risks arising from financial instruments to which the entity is exposed during the period and at the reporting date, and how the entity manages those risks” (International Accounting Standards Board, 2009) .

The IFRS 7 requires information including a complex but not too highly aggregated data about the risk factors. The risk report may be a part of the financial statement, another business report or may be published as a separate document. European financial institutions deliver the risk data using COREP and FINREP reports which are standardized formats provided by European Banking Authorities (EBA) in the XBRL (Extendable Business Reporting Language).

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

Figure 3. IFRS 7 Risk Framework

Source: Redaelli (2007).

Local GAAP regulations are not standardized with the risk disclosure requirements. In particular, they do not include the obligation to literally specify the various kinds of risk as it is in the case of IFRS. The US GAAP standards, for example, concentrate rather on fair value disclosures and require the disclosure of valuation techniques and inputs used to measure fair value (PricewaterhouseCoopers, 2011, p. 61). It should be mentioned, however, that calculating the fair value requires, among other elements, concerning the credit risk, market risk, off-balance sheet risk, significant estimates and their uncertainty.

By contrast, the NL GAAP standards do not have a fair value option. They invoke the previous requirements of IAS 32 that established principles for presenting financial instruments as liabilities or equity and for off-setting financial assets and liabilities (International Accounting Standard 32) . But similarly to the US GAAP, there is no demand of disclosing the exact level of specific risks.

Although the local GAAP allow not to cautiously define the specific risk types, the COREP standard, which is mandated by the Committee of Banking Supervision (CEBS) as obligatory format since 2014, includes the detailed disclosures regarding credit, market and operational risk. A complete set of COREP risk disclosures is presented in the Table 2.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

Table 2. Types of risk disclosures included in the COREP template

Credit Risk	Market Risk	Operational Risk
Credit and counterparty credit risks and free deliveries: Standardised Approach to Capital Requirements	Market Risk: Standardised Approach for Position Risks in Traded Debt Instruments	Operational Risk
Credit and counterparty credit risks and free deliveries: Internal Rating Based Approach to Capital Requirements	Market Risk: Standardised Approach for Position Risks in Equities	Operational Risk: Gross Losses by Business Lines and Event Types in the last year
Credit risk: Equity: Internal Rating Based Approaches to Capital Requirements	Market Risk: Standardised Approaches for Foreign Exchange Risk	Major Operational Risk Losses recorded in the last year or which are still open
Credit risk: Securitisation: Standardised Approach to Capital Requirements	Market Risk: Standardised Approaches for Commodities	
Credit risk: Securitisation: Internal Rating Based Approach to Capital Requirements	Market Risk: Internal model	
Credit risk: Detailed information on securitisations by originators and sponsors	Market Risk Internal Model Details	
Settlement/Delivery Risk in the Trading Book		

Source: European Banking Authority.

Using the COREP template, however, doesn't mean that all entities report every piece of information listed in table 2. Some of them are fully reported, some are reported partially and some are not disclosed because of various reasons. For example, if one concerns the Standardized Approach and Internal Rating Based Approach measures, it should be noticed that they do not always need to be calculated using both methods. In the standard method banks use the regulatory risk weight coefficient, that is based on the quality of the loan quantified by external ratings. The IRB method assumes that the bank is able to calculate the risk using the internal models instead of relying on the outside rating agency.

Data and statistics

The common statistics for the capital adequacy ratio are presented in the table 3. The results shows that European banks on average 12,4% of risk-weighted assets cover by equity, the value of coverage deviates from the mean average of 3,7 percent points. There is quite large gap between the minimum (0,56%) and maximum (18,49%) level of CAR. Distribution is skewed left, thus it should be assumed that more countries have a higher than average rate. Kurtosis is positive, which leads to the conclusion that more observations are concentrated around the center of the distribution.

Table 3. Common statistics for the capital adequacy ratio

	descriptive	value	st. error
CAR	mean	12,39	0,81
	median	12,89	
	variance	13,73	
	standard deviation	3,71	
	minimum	0,56	
	maximum	18,49	
	skewness	-1,45	0,50
	kurtosis	4,38	0,97

Source: Self study based on SNL Financial Database.

Taking into account the aim of the study, that is finding out if the accounting standards influence the number of disclosures, there will be conducted the analysis of variance. It allows to examine whether countries using different accounting standards differ greatly in terms of risk disclosures.

The variable "accounting standards" was simplified by giving it two values: 0-meaning the countries in which both the national and international standards are used and 1-meaning countries where only international standards are required. To create a variable aggregating disclosure range on all listed in the database areas (a kind of risk disclosure index), there were set up the "disc_..." variables, which take a value of 1 for those categories which are disclosed and 0 in the other case (disclosed partially or non-disclosed). Then there was created a new variable "discl.index", which is the sum of the above discrete variables and indicates how much information the individual countries disclose in the reports sent to the European Banking Authority.

For the evaluation of the reliability of the constructed index the Cronbach's alpha coefficient was used. It informs about the degree to which

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

a set of variables describes one hidden in them construct. It can also be interpreted as a measure of the internal consistency of the scale. The Cronbach's alpha coefficient falls within the range between 0 and 1. The high reliability of the scale indicates values greater than 0,7, but a scale for which Cronbach Alpha > 0,6 is considered as acceptable.

In case of the sum of the variables concerning disclosures (discl.index) Cronbach's alpha coefficient is 0,94, which indicates the high reliability of the scale and confirms that the index constructed on the basis of the above data relatively well describes the scope of disclosures. Removal of certain items would give only a very slight improvement in the coefficient.

The next step is checking the assumptions of normal distribution and homogeneity of variance of studied variables (accounting standards and disclosure index). The results are presented in the Table 5.

Table 5. Tests for the normality of distributions

Variable	Shapiro-Wilk		
	Statistic	df	Sig.
IFRS	0,932	6	0,598
local GAAP/IFRS	0,933	12	0,413
discl.index	0,833	5	0,147

Source: Self study based on COREP template of European Banking Authority.

The research uses the Shapiro-Wilk Test, wherein:

H_0 : the dependent variable has a normal distribution

H_1 : $\sim H_0$

In the Shapiro-Wilk tests the sig. value is greater than the significance level of 0,05, so the variables can be regarded as normally distributed.

Then it is allowed to use the Levene's Test for Equality of Variances which verifies the assumption of the homogeneity of variance of the dependent variable within a subpopulation. The hypothesis that the variances of disclosure index are homogeneous is considered to be met if Levene's test $p > 0,05$. In this case $p = 0,032$, thus one have to reject the assumption of homogeneity of variance.

If this assumption turns out to be broken, the Brown-Forsythe and Welch options will display alternative versions of the F statistic which means it can be still verified if there is a difference in the mean of disclosure index within the two subpopulation (divided by taking into account the

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

accounting standards requirements). Table 6 shows results of the Brown-Forsythe and Welch tests.

Table 6. Robust Tests of Equality of Means

	Statistics	df1	df2	Sig.
Welch	0,000	1	18,067	0,992
Brown-Forsythe	0,000	1	18,067	0,992

Source: Self study based on COREP template of European Banking Authority.

For the above tests the hypothesis take the form of:

H_0 : average in the populations are equal

H_1 : $\sim H_0$

In both Welch and Brown-Forsythe tests the significance is at the level of 0,992 ($p > 0,05$). Thus one can accept the H_0 and assume that two independent groups come from populations with the same distribution. Therefore, the accounting standards do not differentiate the scope of disclosures.

It may be also checked whether the scope of the disclosure of information depends on the bank sector stability. In other words– it is an attempt to find an answer to the question whether more stable banking systems are more likely/more demanding in terms of information requirements.

To verify the above mentioned statement the linear regression analysis is used. Table 7 and 8 present the output of the regression coefficients estimations. The results indicate a very weak positive correlation ($R = 0,11$), the variability of disclosure index is explained with the CAR only 0,012%, which means that the model fits the data poorly. The values in Sig. column for both variables are above 0,05. Therefore, there is no evidence to reject the null hypothesis which states that the impact of the variable is not significant. It must be assumed that the variable CAR does not significantly affect the disclosure index.

Table 7. Model summary

Model	R	R-square	Adjusted R-square	St. error of the estimate

CAR	-,242	,527	-,108	-,460	,651

Source: Self study based on COREP template of European Banking Authority and SNL financial Database.

Summarizing, on the basis of the tests presented, we can conclude that the selected countries do not differ from each other in terms of disclosed data according to accounting standards. Also the level of their solvency measured by the capital adequacy ratio does not affect the scope of disclosures.

Thus, for the purposes of identifying the factors affecting the transparency in the banking sector one should focus on the analysis of the legal regimes of individual countries belonging to the transnational financial safety net organizations, as well as historical and cultural factors related to the transparency of economic activity, particularly in the area of financial markets.

Conclusions

The Basel Committee on Banking Supervision defines the transparency as ‘the public disclosure of reliable and timely information that enables users of that information to make an accurate assessment of a bank’s financial condition and performance, business profile, risk profile and risk management. This definition recognizes that disclosure alone does not necessarily result in transparency’ (Basel Committee on Banking Supervision, 1998, p.4).

That is a crucial notice when the above presented results are concerned. It should be emphasized that although the accounting standards do not differentiate the number of disclosed data, they may affect the quality of the information given to the public. It seems then that the debate on risk disclosures should concentrate not on their scope which is quite standardized, but on the credibility of the data.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

The information put in the public domain should be reliable to fulfill the function of mitigating the information asymmetry problem. The 2007 financial crises proved that the quality of information – both given directly by banks and by market intermediaries, such as credit rating agencies – is poor and misleading. If the data credibility is provided, then the authorities may concern the problem of the scope of disclosures.

There are several arguments for increasing the number of released information (Linsley, Shrives, 2005, p. 206). Firstly, the relevant information about the risk policy and management enables the market participants to sanction banks with unsatisfactory risk profile. On the other hand, well managed banks may benefit by decreasing their cost of finance, because of the greater confidence of the investors. Secondly, the requirement of disclosing the risk level obliges the managers to work out the adequate early warning systems, which may be useful not only to estimate the level of presently undertaken risk, but also to predict some threats and plan prudential procedures. Eventually, the competition within the banking sector forces the banks to fight for the trust of depositaries, stockholders, investors and contractors. The specific role of the financial institutions causes that they earn trust not only with the increasing profitability but also with the better prudential policy. If they are require to disclose this kind of information they would probably improve the risk management to enhance their economic standing and competitiveness.

Taking all this arguments into account it seems to be essential to take care about the scope of risk disclosures and find the determinants of the number of disclosed data. The presented study proves that if the European banking sector is concern it does not depend on the accountancy standards, nor on the stability of the sector (if it is measured with the capital adequacy ratio). It is therefore necessary to review the other determinants of disclosures (regulatory agency requirements for financial markets, the degree of development/market size, etc.). It should be remembered at the same time that the prerequisites of transparency is not only the great number of disclosed information but also: timeliness, comprehensiveness, reliability, relevance, comparability and materiality of the reported datasets (Linsley, Shrives, 2005, p. 206).

Health Care Systems' Evolvement and the Changing Role of the State in Selected CEEC

JEL Classification: *O57; L38; L30*

Keywords: *health care reforms; Central and Eastern Europe; financing health care; privatization of health care services*

Abstract: Despite common heritage, Bulgaria, Czech Republic, Estonia, Hungary, Latvia, Lithuania, Poland, Romania, and Slovakia (hereinafter Central and Eastern European Countries – CEEC) opted for different models while reforming their health care systems. A common (and important) component of these reforms was privatization and introduction of various market mechanisms in health care systems. The objective of the paper is to identify main challenges resulting from the health care reforms in CEEC. Review of the literature (using EBSCO and ScienceDirect databases) on the results of the health care reforms in CEEC will be followed by an analysis of the changes in health care financing in CEEC between 1995-2012 with a special emphasis on the role of the state in this process. WHO statistics (data) on national health care expenditures divided further into: total health expenditure, general government expenditure, private expenditure, and out of pocket expenditure (with various configurations) will be used. It is argued that health care reforms led (among others) to shifting the financial risk to patients and the state is slowly (and continually) withdrawing from financing health care in CEEC. This diminishing share of state financing of health care is not compensated by tax deductions and/or other forms of allowances. Also the issue of restricted access to health care is indicated here as a by-product of the health care reforms undertaken in CEEC.

Introduction

Health care systems and their functioning always attract public attention due to the universal value of good health for everybody. Democratic governments have to justify any kind of state intervention by reference to either market failure or distributive goals. As health services are commonly acknowledged as vulnerable to market failures (Arrow, 1963, pp. 941–973) and as a prototype of a merit good (Musgrave, 1959), state involvement can be justified by the public interest in guaranteeing effective, affordable, and accessible healthcare for the entire population (Culyer, 1989, pp.34–58; Barr, 1993, pp. 289–335).

States and governments act as principals in deciding on organization, service delivery and financing of the health care systems. The role of the state in this respect cannot be overestimated and one may maintain that the state's responsibility for proper functioning of health care systems is not being questioned. It seems to be interesting to analyze how is the role of the state in health care organizing, delivery, and financing in countries undertaking profound social and economic transformation. While processes of reforming health care systems in post-communist countries are comparatively well documented in the literature (Voncina et al., 2007, pp.144-157), there is a lack of sources analyzing the evolving role of the state in these processes. The paper is aimed at showing a continuous withdrawing of the state from financing health care systems.

Methodology of the research

The paper is based on a desk study i.e. metaanalysis using sources from EBSCO and ScienceDirect databases. The following keywords (in various combinations) were used: health care reforms, restructuring of health system, CEE countries as well as names of countries at hand: Bulgaria, Czech Republic, Estonia, Hungary, Latvia, Lithuania, Poland, Romania, and Slovakia. The selection process had three stages. The first step was to identify sources which titles corresponded to the topic and the goal of the paper. There were 283 results (altogether) showed, out of which 114 were classified as appropriate for further inquiry. During stage two all the abstracts were read and then only papers directly addressing issues of health care reforms in Central and Eastern European countries and the role of the state in these processes were identified (there were 14 such papers). In the end (the last stage) these 14 papers were read in full and analyzed. In addi-

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

tion, publications from WHO Regional Office for Europe were used in this paper.

Empirical component of the paper is built on WHO statistics. Data Explorer available at <http://apps.who.int/nha/database/Select/Indicators/en> was used for the construction of Table 1.

State in health care system organization and functioning

It is assumed here after Foucault (1991, pp. 87-104, p. 91) that the state is not narrowly perceived as responsible first of all for legal regulation and execution, but also is seen as a creator of institutions, a driving force for creating tactics allowing for real execution of political power assuming that political power centers are located also out of governmental agencies (Miller & Rose, 1990, pp. 1-31).

Health system is understood as all the activities whose primary purpose is to promote, restore, or maintain health (WHO 2000) but in this paper it is narrowed down to those activities, which are under complete or partial control of governments. The private sector in health is not excluded from consideration, because of at least two reasons. First is because governments play an important regulatory role that can influence the performance of private providers and second because growing number of governments' tasks is delegated/transferred to private sector organizations (Kruk & Freedman, 2008, pp.263-276).

The role of the state in health care system - like in disputes on the role of the state in economy – is not commonly accepted. The essence of the controversy lies in the role of state intervention, particularly the extent to which it controls the provision, funding, and regulation of medical services. Opponents of state intervention and proponents of “privatization” contend that the deeper government becomes involved in health care, the more bureaucratic, complex, inefficient, and inferior the services (Hamowy, 2000, pp.15-86). Advocates of state intervention, on the other hand, argue that government participation is the best way to improve both cost-effectiveness and accessibility of health services (Barlett & Steele, 2004; DeBakey, 2006, pp.145-157).

The UN's Committee on Economic Social and Cultural Rights (2000) maintains that states are obligated to ensure availability, accessibility, acceptability, and quality of health services.

Following Veillard et al. (2001, pp. 191-199) six governmental tasks in respect to health care sector can be identified:

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

- setting health care system vision and strategy,
- influencing other sectors to improve public health,
- managing health care system based on shared social values,
- ensuring that health care system is constructed to achieve health goals,
- better implementation of legal and regulatory instruments available,
- collecting, gathering, compiling, disseminating and using information.

These tasks formulate the basic set of the state activities in respect to health care sector. Following Kutzin (2001, pp. 171-204) one can extend this list by insurance function according to which the state should guarantee access to health care without further financial impoverishment of households and citizens.

The role of the state in health care systems has been evolving. Nowadays, one may notice considerable less direct state involvement in health care systems. Böhm et al. (2013, pp. 258-269) using three criteria: regulation, financing, and service provision have distinguished five models of health care systems in OECD countries: National Health Service, National Health Insurance, Social Health Insurance, Private Health System, and Statist Social Health Insurance. In these models, the state retains its decisive role only in respect to regulation (and even here in four out of five models). Financing is dominated by societal and/or private actors (three out of five models) so is provision of health services (four of five models). This in turn may lead to the conclusion that the state remains to play a decisive role in just one out of these three criteria.

Smart governance for health and well-being

Even limiting its involvement in health care system, the state is responsible for ensuring availability, accessibility, acceptability, and quality of health services. Here the concept of smart governance could help. Smart governance for health defines how governments approach governance for health challenges

strategically in five dimensions, through:

- collaboration,
- engagement,
- a mixture of regulation and persuasion,
- independent agencies, and
- adaptive policies, resilient structures and foresight (Kickbusch & Gleicher, 2012, p. 53).

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

Smart governance can also be understood as the application of smart power, defined as the combination of the hard power of coercion and payment with the soft power of persuasion and attraction. Whereas hard power (such as using or threatening military intervention, economic sanctions) and soft power (such as diplomacy, economic assistance and communication) are wholly descriptive terms, smart power also involves evaluation. Smart governance for health and well-being means that the state is engaged in more complex relations with government and societal actors, using both hard and soft power. This does not inevitably reduce its role or power; indeed, with regard to health governance and governance for health, states have expanded their power to meet new challenges through new collaborative arrangements.

An example of a mixture of regulation and persuasion can be dual practice. Physician dual practice is a widespread phenomenon which has implications for the equity, efficiency and quality of health care provision. Some governments fully prohibit this practice, others regulate or restrict dual job holding with different intensities and regulatory instruments. The measures implemented include limiting the income physicians can earn through dual job holding, offering work benefits to physicians in exchange for their working exclusively in the public sector, raising public salaries, and allowing physicians to perform private practice at public facilities (García-Prado & González, 2007, pp. 142-152). This phenomenon is observed virtually in all CEE countries.

Health care reforms in CEE countries: main trends

Health care reforms are undertaken virtually everywhere in today's world. This is because of the growing health care costs (Hartwig, 2008, pp. 603-623) pushed by innovations, new medical technologies and innovative pharmaceuticals (Mossialos & Le Grand, 1999). Consequently, reforms aimed at increase of efficiency and cost reduction are introduced (McPake, Kumaranayake & Normand 2002).

There are certain ways and tools widely used in many countries reforming their health care systems to mention decentralization of health care delivery (Mosca, 2006, pp. 113-120), introduction of new concepts like Diagnosis Related Groups, Health Technology Assessment, or Clinical Practice Guidelines (Perleth, Jakubowski & Busse, 2001, pp. 235-250).

One of the common feature of nearly all of the health care reforms is introduction of market mechanisms in health care and private sector devel-

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

opment and expansion (Peterson, 1998). Private sector expansion in health care sector is noticed in EU countries (Thompson & McKee, 2004, pp. 281-291), CEE countries including. Further expansion of private sector in health care systems is recommended even in countries where public health care system is effective and positively assessed (Janssen, 2002, pp.145-159).

As stated by Uplekar: „ During the last decade there has been considerable international mobilisation around shrinking the role of States in health care” (Uplekar, 2000, pp. 897-904, p. 897). It is worth to notice that recommendations aimed at further private sector development in health care systems were formulated despite some negative consequences of such attempts documented in the literature (Brockmann, 2002, pp. 593-608; García-Prado & González, 2007, pp. 142-152; Horton, 2006, pp.2702-2714).

The six common features of health care reforms undertaken in Central and eastern European countries were as follow:

- introduction of an insurance model/scheme (social insurance). According to the new model only insured individuals are entitled for health care services (enumerated in the law) free of charge. Insurance is obligatory with just a few exceptions.
- provider-purchaser split. This means that financing health care services was separated from their delivery.
- empowerment of independent public health units. Public health care units were given more scope of decisions (i.e. more discretion in respect to operational and strategic decisions) but at the same time were obliged to cover possible debts.
- introduction of competition between health care providers (in respect to both public and private ones) for public funding. The payer is purchasing health services on a competitive basis, i.e. contracts are signed with these providers who offer the best prices and guarantee timely, good quality services.
- broadening the scope of private sector in the health care including provisions for the possibility to set up and run private establishments in the health care sector.
- abandonment of financing resources (i.e. beds, wages, facilities) and paying for services only (goals financing) in the form of individual contracts with the purchaser. It can be indicated that there are considerable differences in the assessment of the outcomes of the reforms undertaken. For example the results of the health care reforms in Czech Republic were very positively perceived by some Czech doctors (Antono-

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

va et al. 2010, pp. 179–181) while contested by others (Oborna, Licenik & Mrozek, 2010, p. 2071).

Health care expenditures in CEEC: 1995-2012

The development of the private sector in CEE countries was accompanied by growing share of private funds in financing health care systems (see Table 1). The application of patient cost-sharing in health care is occupying political discussions in Europe, since its importance as a tool to control the increasing public spending on health is rising considerably (Baji et al. 2011, pp. 255– 262). This is also the case in Hungary, Slovakia, and the Czech Republic. In these countries, cost-sharing for commodities (e.g. pharmaceuticals and medical devices) and payments for services that fall (partly or fully) outside the health insurance funds, have long been applied, and constitute a notable share of total health expenditure (Rechel & McKee, 2009, pp. 1186–1195).

However, these countries also have experiences with user fees for primary, outpatient and inpatient services covered by social health insurance. Such user fees have been recently introduced in the Czech Republic. In Slovakia and Hungary, user fees for services were implemented and abolished shortly after their introduction (Kossarova & Madarova, 2008, pp.10-12). Experiences from these Central European countries show that the introduction of user fees for health care services meets strong opposition by political opponents and the general public (Hall, 2009). The introduction of user fees for health care services (called visit fee) was part of the reform arrangements carried out by the government in 2007 comprising the Convergence Program of Hungary (Baji et al. 2011, p. 256). The goal of the program was to decrease the deficit of the government budget and to meet the European Union criteria for countries in transition to join the Euro zone (known as “Maastricht Criteria”). The main goals of the introduction of the visit fee were to decrease unnecessary use of health care services and to convert the informal payments into formal health care charges.

The visit fee was introduced in February 2007 for GP, outpatient specialist, inpatient and dental care. The charge for co-payments was 300 HUF (1.1 Euro) for each visit to a GP and outpatient specialist with a referral, and 600 HUF (2.2 Euros) in the case of using outpatient specialist care without a referral. In inpatient care, a charge of 300 HUF (1.1 Euros) was introduced per day of hospitalization. In case of unnecessary use of emergency care, 1000 HUF (3.7 Euros) had to be paid. The beneficiary was the

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

provider institution, or the physician in case of GPs. Children under the age of 18 and users of certain health care services (e.g. emergency care, some chronic care/treatments, prenatal and preventive care) were exempted. Moreover, a limit was introduced and defined by a maximum of 20 visits/days hospitalization per year. The payments after these 20 visits/days hospitalization a year were reimbursed by the state. However, the system of visit fee worked for only one year. In April 2008, the payments were abolished as a result of a referendum initiated by the opposition. Participation in this referendum was high (e.g. higher than in the parliamentary elections in 2010). About 50.5% of the population who was entitled to vote, took part. In total, 82.4% of the voters supported the abolishment of the visit fee for physician visits, and 84.0% of voters supported the abolishment of the user fees for hospitalizations. Evidence shows that during the period of visit fee, health care utilization decreased by 15–20% in GP and outpatient services as well as days spent in hospital

(Boncz et al. 2008, pp. A368–9). However, one has to highlight that other elements of the complex reforms could have also contributed to the decrease in the number of visits and days spent in hospital. This could have included the change of the prescription system (i.e. physicians were allowed to prescribe medicine for a longer period, as a result fewer patients' visits were required) and the structural reform of inpatient care (namely the decrease of acute bed capacity by 25%, which might have also contributed to less hospitalizations). The amount of revenue generated by the user fee was estimated to be about 22 billion HUF in 2007, i.e. 4–5% of public health care expenditure (Baji et al. 2011, p. 256).

The Hungarian case with the visit fee shows only a part of the bigger picture. Table 1 below offers aggregated data on the share of private funds used in the health care sectors of Central and Eastern European countries between 1995 and 2012.

As indicated in Table 1 the share of private expenditure in the total health expenditure in 2012 varies from 15% in Czech Republic to 44% in Bulgaria. Bulgaria notices also second to the highest share of out of pocket expenditure in private expenditure on health (98%) following Romania with 98% share. Bulgaria leads also the ranking of the highest share of out of pocket expenditure in the total health expenditure (42% as compared to 14% in Czech Republic). Certainly, Bulgarian citizens bear the highest burden of restructurization of their health care sector among the analyzed countries. It is also worth to mention that the high share of out of pocket expenditure in the private expenditure on health to great extent is the result

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

of weak private health insurance schemes in vast majority of CEE countries (Hungary, Poland and Slovakia with their shares ranging from 74-77% being exceptions). Between 1995-2012 in all analyzed countries (but Romania), the share of out of pocket expenditure in the total health expenditure has doubled indicating growing financial burden imposed on households and individuals. This can be interpreted as a way of withdrawal of the state from financing health care. It should be addend that this withdrawal of the state is not compensated (at least partially) by various tax exemptions and/or any other concessions. This in turn means that the state is transferring the responsibility for financing health care to the citizens without any compensation.

Table 1. Health care expenditures in selected Central and Eastern European countries: 1995-2012

Country	Indicator	1995	2000	2005	2006	2007	2008	2009	2010	2011	2012

Conclusions

Bulgaria, Czech Republic, Estonia, Hungary, Latvia, Lithuania, Poland, Romania, and Slovakia have been proceeding with health care reforms over the last quarter of the century. Changes in health care systems were implemented according to liberal ideologies aimed at introduction of market mechanisms into health care systems accompanied by the development of private sector in health. Market and private sector development in health resulted in diminishing public funding and health care delivery. The growing share of private expenditure in the total health expenditure shows that the state is slowly but continually withdrawing from the health sector, shifting financial risk on the shoulders of individuals. Citizens are not compensated for growing financial burdens neither private health insurance is promoted and developed. This in turn means that the share of out of pocket payments both in private health expenditure and the total health expenditure is exceptionally high in CEE countries.

**Monetary Valuation of Intellectual Human
Capital in Innovative Activity**

JEL Classification: *O31; M52; J33*

Keywords: *intellectual human capital; value; valuation; innovation activity*

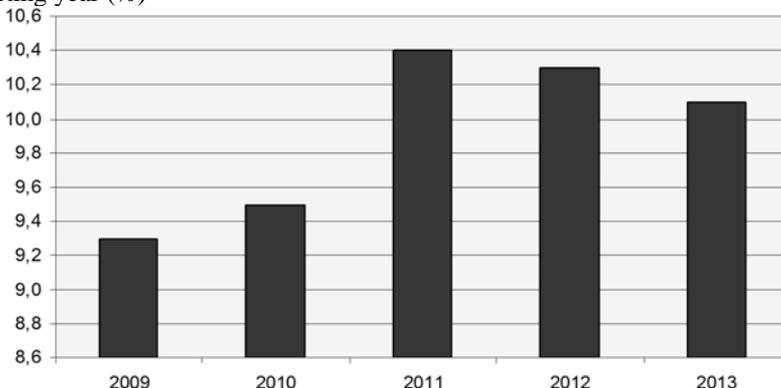

Abstract: The article views the structure of an organization's intellectual human capital, which integrates both employees' intellectual, professional and personal abilities to perform innovation activity and their results achieved in the process of this activity. The authors prove the role of intellectual human capital in improving an organization's innovation activity. Basing on the cost, income, expert and psychological approaches, the article develops the intellectual capital monetary valuation model focused on an increase in the objectivity of measuring its value by means of the individual intellectual and performance report. The application of this model is aimed at activating the innovative development of social and economic entities by increasing the quality and efficiency of intellectual human capital.

Introduction

In the light of the recent external political challenges, the increase in the efficiency of Russia's innovative activity is one of the necessary conditions to transit to a new economic policy focused on accelerating socio-economic development, on technological renovation and knowledge economy.

In the present time, the problem of organizations' low innovation activity is extremely urgent. According to the official statistical data, the percent of organizations that implement technological, organizational and marketing innovations is 10.5% and tends to decrease (fig.1).

Figure 5. The share of organizations that implement technological, organizational and marketing innovations in the total number of surveyed organizations in the reporting year (%)

Source: In accordance with the official statistical data of the Rosstat, "Science and innovations" (2014).

This situation mostly deals with the unsatisfied condition of intellectual human capital integrating two interrelated elements – intellectual potential and the results of the innovation activity of labour resources. As evidenced by the Global Competitive Report 2014-2015, Russia is ranked 53rd out of 144 countries, in part due to its weak positions based on the human factor-related indicators: Quality of the educational system – 83; Quality of management schools – 104; Availability of scientists and engineers – 70; Country capacity to retain talent – 103; Country capacity to attract talent – 92; Reliance on professional management – 85; Cooperation in labor-employer relations – 89; Firm-level technology absorption – 98; Capacity for innova-

18-19 June 2015, Economics and Finance**

tion – 66. This generally shows the Russian society's weak capacity to efficiently use the existing knowledge and create some new knowledge.

Thus, it is of high priority to change to the human-oriented concept of innovative activity management to increase the competitive power of the Russian economy in the global market. This suggests applying a new model of integrated intellectual human capital measurement, which would reconcile the interests of both the employee and the manager in distributing earnings from the use of individual intellectual capital, and which would foster the motivation of the personnel to innovation activity, thus increasing the innovation activity of the organization.

A distinctive feature of this model must be associated with not only personnel cost accounting but also the estimation of such parameters as the contribution of each employee in an innovative product, the degree of implementation of intellectual and personal potential in the process of innovation, the harm from the absence of a worker.

The objective of this research is to develop the intellectual human capital model of monetary evaluation focused on intensifying the innovation activity of an organization. The aforementioned objective has defined the following tasks of the research:

- To expand the terms of “innovation activity” and “intellectual human capital” from the standpoint of the human-oriented management concept;
- To prove a significant role of intellectual human capital in increasing the innovation activity of an organization;
- To propose the intellectual human capital model of monetary evaluation, taking into account employees' social and psychological characteristics;
- To determine the areas of application for the proposed model.

Methodology of the research

Many research works have been devoted to the issues on how human, social and intellectual capital influences innovation activity (Wu, Wann-Yih, 2006; Teo, Stephen T. T., 2014; Ugalde-Binda, Nadia, 2014; Lu, Wen-Min, 2014; Carraro, Carlo, 2014). This article gives the authors' view on the structure of an employee's intellectual capital and on its monetary valuation as a key factor of the efficiency of a company's innovation activity.

We suppose that the employee's intellectual capital contains two interrelated elements; the one is a genetic or natural component (intelligence) and the other is a manmade component that has been obtained in a development

process (the results of intellectual and innovation activity). These components ensure the employee's success and, as a result, the organization's efficiency, which is reflected in achieved social and economic benefit in respect of an individual or a business in general (promotion at work, competitive advantages, bonuses, yields from implemented items of intellectual property, a higher business value, etc.).

To achieve social benefits (recognition of his true value by colleagues, satisfaction with the quality of work), the employee should demonstrate his intellectual abilities, personal qualities, professional knowledge, and position-related skills. Here, only non-financial evaluation based on socio-psychological methods and expert evaluation techniques seem to be possible. But these must be accounted for as a special coefficient in the monetary evaluation of an employee's intellectual capital. This coefficient is defined as the arithmetic mean of two indicators – i.e., the indicator of the employee's intellectual potential and the indicator showing the employee's personal contribution in the organization's innovative development.

The integral indicator of the employee's IPI (*Intellectual potential of an individual*) is proposed to calculate by formula 1:

$$IPI = \sum_{i=1}^6 k_i A_i, \quad (1)$$

Where A_i ($i = 1..6$) – point-based valuation of the types of intellectual potential (sensorial, emotional, thinking and logical, creative, socio-cultural, and economic); k_i ($\sum k_i = 1$) – weight coefficient.

In determining weights, it is recommended to use the simplified approach - all types of intellectual potential are equal – and the expert approach - weight depends on the importance degree of intellectual potential determined by experts in respect of each separate position and/or situation), which ensures the adjustment of the indicator to various evaluation objectives.

The procedures of valuating the types of individual intellectual potential (A_i) are based on applying the authors' personality questionnaire (O. Loseva, 2014, pp 91-107).

To make the IPI integral evaluation with formula 1, all types (A_i) must have a similar range of changes. To meet this goal, it is recommended to apply the approach from quality statistics (V. Vasilyev, 2004, pp. 153-168). Each type of intellectual potential is described as a set of attributes (X_j);

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

e.g., concerning the content-related field of sensorial intellect perception, such attributes include integrity, constancy, apperception, and emotional overtones.

To determine the quality of each property, it is necessary to set a quality standard taken as a number of quality categories. In this case, it is suggested to choose five categories corresponding to the degree of manifestation of this or that attribute that belong to a definite type of intellectual potential: “low” – 1; “below average” – 2; “medium” – 3, “above average” – 4, “high” – 5.

Each type (A_i) is estimated as the arithmetic mean of the values of definite attributes:

$$A_i = \frac{\sum_{j=1}^m X_j}{m}, \quad (2)$$

Where X – value of an attribute; m – number of attributes.

In turn, the attribute (X) is also estimated as the arithmetic mean of the points gained in answering those test questions that serve to determine a degree of manifestation of the attribute (X) in the respondent. Thus, all types of intellectual potential receive quality-related valuation ranging from 1 to 5.

Analogically, the indicator (At) is calculated by the following formula based on the expert approach:

$$At = \sum_{i=1}^p k_i J_i, \quad (3)$$

Where p – number of key indicators that reflect the non-financial results of an employee’s labour activity influencing his success in achieving social benefits ($p \leq 20$ is recommended); J_i – point-based valuation of a definite indicator, which is made by experts on the basis of attestation or testing (it is recommended to apply the same grades as for the structural components of the intellect - from 1 to 5); k_i – weight coefficients set by experts in respect of the importance of a definite indicator for a definite position at the current stage of the organization’s development in accordance with the principle “the higher the importance, the higher the range”, while $\sum k_i = 1$.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

The indicators can be associated with the following groups:

- 1) Position-related characteristics: length of employment and education degree; professional competence; quality of work; responsibility and discipline; initiative;
- 2) Personality-related characteristics: educational activity (capacity for learning, self-education and training of other people); communication abilities; leadership skills; observance of both social standards and principles of corporate culture; level of work motivation; loyalty; commitment to an organization, its values, interests, aims, etc.;
- 3) Contribution to an organization's innovative development: number of experiences of participation in innovative projects, seminars and presentations over the period (t); number of rational proposals and novelties made over the period (t); number of applications for patent made over the period (t); number of instructions, technologies, methods developed over the period (t), etc.

The indicator's number and content can vary from the type of an organization's activity. The period (t) is determined by the frequency of attestation and is, as a rule, 1 year.

As the indicators (IPi) and (At) are calculated via expert valuation techniques, it is necessary to determine the degree of consistency of experts' opinions in choosing the indicators and weights using the concordance coefficient by formula 4. Experts' opinions are concordant if $w \geq 0.75$.

$$w = 1 - \frac{\sum_{i=1}^m \sum_{j=1}^m \sum_{k=1}^n |x_{ik} - x_{jk}|}{nm(m-1)(K-1)}, \quad (4)$$

Where m – number of matrix lines (number of experts); n – number of matrix columns (attributes); K – number of chosen levels of quality; x – qualitative analogue of a quantitative indicator that is determined by interval scaling.

Economic benefit deals with earning income by an employee from his intellectual activity. First of all, it is necessary to highlight two interrelated roles of an employee – a holder and an owner of intellectual capital. Being only an owner of intellectual capital, the employee is entirely a functional element of the system, whose status doesn't deal with the possibility to participate in management, including a special influence on distributing income from using his intellectual capital. The employees' labour is an intellectual and routine process that produces information on already

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

known knowledge. In this case, the employee himself is considered entirely as a hired worker and receives wage compensation for his labour with no claims as to a part of profit. The employee as an owner of intellectual capital directs it to generating new knowledge and practices his unique experience, thus being capable of claiming to receive monopoly earnings. The only difficulty deals with the fact that in executing innovative projects one and the same employee with definite intellectual abilities and professional and personal qualities can be both an owner of intellectual capital (a generator of ideas, a holder of unique experience) and a hired worker implementing the ideas and experience of other people.

We think that the valuation of an employee must take into account both his value as a hired worker and his profit from using his own intellectual capital despite the risk of double-counting because this valuation is intended primarily for managing purposes (the formation of the mechanism for motivating and encouraging innovation activity, for improving HR-management, etc.).

In practice, an organization's management staff should trace investments (expenses) in the elements of intellectual human capital, on the one hand, and the profit which has been gained by it from such investments, on the other hand. This may evidence the reason to use the financial models based on both the cost approach and the income approach in evaluating the economic benefit of an employee.

The aforementioned approaches are a methodological basis for developing the human intellectual capital model of valuation.

The intellectual human capital valuation model in innovation

Measuring human intellectual capital is an integral part of the process of innovation activity management. We suppose that the human-oriented concept is the most adequate technique for managing innovation activity; its peculiar features can be formulated, analyzing both the evolution of the concepts as a result of social development and the changes of the prevailing type of economy: industrial economy → information economy → knowledge economy (Table 1).

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

Table 1. Evolution of innovative activity management concepts

Characteristics	Tech-oriented	Information-oriented	Human-oriented
Economic prerequisites:			
Stage of social/economic development	Industrial	Postindustrial (information economy)	Postindustrial (knowledge economy)
Main productive force	Technics, objects of labour	Technology, tools of labour, sciences	Human intellect, knowledge
Main types of innovative resources	Material, financial	Informative and communicative	Intellectual, human
Prevailing type of innovative behavior	Passive	Passive and active	Active
Prevailing types of innovations	Product-related, technical	Technological, managerial, informative	Social, cognitive
Theoretical approaches to management:			
- Name of approach	Factor-related, functional	Functional, systemic	Systemic, situational
Characteristics of management providing the interrelation “Human being ↔ Innovative process”:			
- Innovative activity of employees	Low	High in high-tech industries	High in all spheres of activity
- Prevailing methods of motivation	Material	Material, organizational	Moral and psychological
- Priorities in employee valuation	Professional skills, knowledge	Social and psychological peculiarities, needs, motives	Intellectual abilities, satisfied quality of labour
- Employee development management	Professional training	Professional training, social and psychological development	Development of intellectual and innovative potential
- Accounting of innovative activity results	Not performed	Performed at the level of groups, communities	Performed at the level of individual
Characteristics of management providing the interrelation “Human being ↔ Human being”:			
- Prevailing style of management	Authoritative	Democratic	Democrtic and delegating
- Character of interrelations	Superior - inferior	Collegial and collective	Collaborating and personal
- Forms of activity organization	Individual	Group	Team
- Involvement of innovative activity in management	Practically no involvement	Executors are involved in management	Participative management

Source: own work.

The application of the concept of human-oriented innovative activity management needs a broader meaning of the term “innovative activity” and a different understanding of the term “human capital” as a part of an organization’s intellectual capital.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

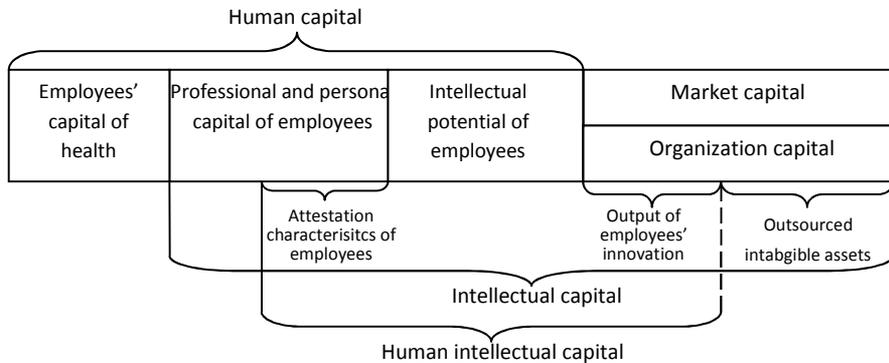

We propose to consider innovative activity as a set of actions done by the participants of not only an innovative project but also any process related to the use of the human intellect for the development of the socio-economic system. Basically, we mean intellectual and innovative activity.

To encourage employees' innovative activity and to use their intellectual potential to the full extent for the development of an organization, it is reasonable to extend the understanding of an employee's intellectual capital. We suppose that this concept should include not only the employee's intellect, gained knowledge, abilities and skills (i.e., inalienable capital) but also the products of his intellectual and innovative activity – formalized knowledge and information as well as developed productive relationships with his colleagues and the organization's outer environment (i.e. alienable capital). As a result, the organization oriented to innovative development is recommended to consider intellectual human capital (human IC) as an independent type of capital that will contain the components of an organization's human and intellectual capitals in their traditional understanding (fig.1). In the figure, the dashed line means that, together with the traditional approach referring created and legally registered intangible assets to an organization's intellectual capital, it is proposed to use the approach characterizing the belonging of both the given objects and other intellectual results, which haven't been legally registered, to an employee (a group of employees), i.e., to intellectual human capital. Such an approach enables one to evaluate the performance efficiency of employees, creative teams and divisions and to determine return on their intellectual potential, thus developing more accomplished mechanisms of motivation, encouragement and controlling in respect of innovative activity.

Thus, human IC integrates both the intellectual and attestation characteristics of human capital and the results of its innovative activity that, after their formalization and alienation, are incorporated in corporate and market intellectual capital.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

Diagram 1. Intellectual human capital in the structure of human and intellectual capitals of an organization.

Source: own work.

This understanding allows considering human IC as the main factor of a higher innovative activity of an organization. Innovation is a result of idea transformation into research projects, new and upgraded hi-tech or socio-economic solutions that are recognized after being in every-day use. Therefore, innovation (idea) is one of the forms of the intellect of a person/a group of people with a further implementation in the results of intellectual and innovative activity and their use in practice. A significant role of human IC is determined by the nature of the innovative process itself. Moreover, at the different stages of the life cycle of an innovative product, a major role is played by the different types of intellectual human capital:

- 1) The intellectual capital of an employee (a group of employees) is the most important for generating innovative ideas;
- 2) The condition of the intellectual capital of an organization (including small business entities) defines the success of implementing and commercializing innovations;
- 3) The quality of the intellectual capital of a region (a country in general) and the level of the development of innovative culture significantly influence the frequency of the occurrence of new innovations and the duration of the innovation cycle.

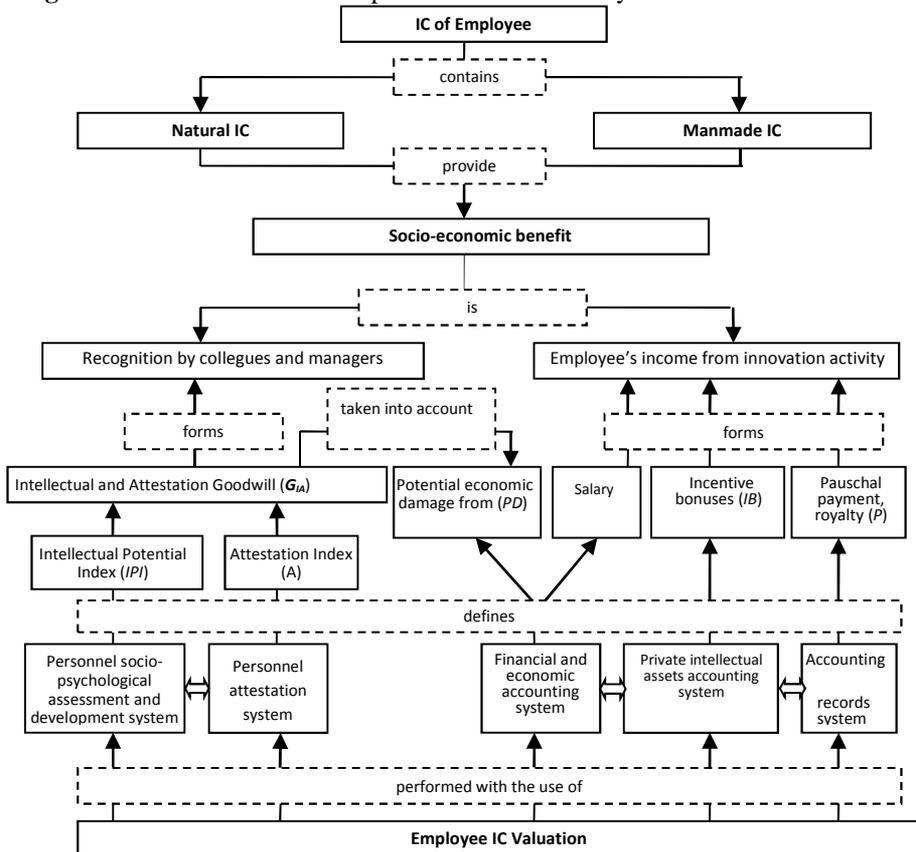

On the basis of the foregoing, the level of the innovation activity of an organization can be expressed by the value of intellectual human capital, which will also be the integral indicator of this organization.

The model for evaluating an employee's intellectual capital is given hereinafter (Diagram 2).

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

In order to increase benefits from individual intellectual capital, this model should be primarily applied in respect of specialists-innovators being idea generators and unique experience holders as well as top managers and intellectual workers. The value of individual intellectual capital will be characterized by the value of an employee, which is variable and depends primarily on his efficiency within a definite period of time (as a rule, per year). On the other hand, these are the achieved results that influence the readiness of the managers of an organization for expenditures with the aim of not only retaining a valuable employee but also creating conditions to develop their creativity potential.

Diagram 2. Intellectual human capital model of monetary valuation

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

If fact, for the organization, the value of the intellectual capital of the employee (i) is the aggregate amount of expenses (real and potential) and is determined within the period of time (t) by the following formula:

$$V_i(t) = ED + S + IB + P + PD \cdot G_{IA} \quad (5)$$

Where:

ED – expenses for the development of an employee per period (t), including as follows:

- Expenses for professional advanced training, career promotion programs;
- Expenses for the socio-psychological assessment of an employee's intellectual potential;
- Expenses for the development of an employee's intellectual abilities (training courses, intellectual potential development programs, coaching).

S – Salary of an employee for executing his job-related duties per period (t). It includes a basic rate of compensation in accordance with an employee's qualification and education level, status allowance for position-related difficulty, individual bonuses (premiums) for efficient work in accordance with position-related instructions, and excludes social benefits and subsidies, collective allowance following the results of an organization's work, allowance for labour conditions and risks;

IB – Incentive bonuses and payments to an employee for his contribution in the development of an organization, including innovations (participation in innovation projects, rational proposals, formalization of knowledge by methodological development, etc.), the amount of which can be determined on the basis of an employee's share participation in the distribution of an organization's benefits per period (t);

P – Profit of an employee from items of intellectual property legally alienated and created individually or in a team;

PD – Potential damage, i.e., valuated aggregate costs borne by an organization in case of an employee's possible termination of service as of the end of the period (t):

- Expenses of an organization for the search of the equivalent employee (expenses for independent search, recruiting agencies, advertisements, etc.);
- Economic damage experienced by an organization per period related to the replacement of an employee, who has left, to a new one (a decrease in product volume and quality, expenses for a new employee's training and adaptation, re-training of another employee);
- Economic damage from changes in the systemic impacts of synergy and the emergence of the members of a group, which an employee has belonged to;
- Damage from an employee's move to competitors related to the possibilities of the loss of a part of market segments, a competitor's higher sales and his stronger influence in the market (valuation of damage from transferring formal-

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

ized intellectual projects and copyright in items of intellectual property to a competitor, from disclosing commercial secrets, etc.).

Potential damage must be adjusted for the coefficient (G_{IA}), which depends on the intellectual and attestation index (IA):

$$IA = \frac{1}{2}(IPI + At) \quad (6)$$

Determining the indexes (IPI) and (At) is given hereinabove in the research methods section.

As a result, $G_{IA}=0.5$ if $IA < 2.5$; $G_{IA}=1$ if $2.5 \leq IA < 3.5$; $G_{IA}=1.5$ if $3.5 \leq IA < 4.5$; $G_{IA}=2$ if $IA \geq 4.5$.

The most challenges deal with valuating payments to an employee (P) for creating items of intellectual property (IPI). They must account for IPI creation and implementation expenditures, on the one hand, and for the prospective value of income from IPI commercialization, on the other hand.

At the first stage, the analysis is conducted in respect of expenditures on creating, registering and protecting an employee's items of intellectual property:

$$ET = T \cdot p \cdot k_d, \quad (7)$$

Where ET – expenditures of an employee's toil;

T – expenditures of time for IPI development, creation and registration expressed as hours;

p – price for an employee's working hour related to either producing or other activity performed by him;

k_d – coefficient of intellectual product complexity based on public, industrial or corporate standards.

In a second stage, it is necessary to calculate an anticipated production volume for those innovative products that have been created with the use of IPI , taking into account return on the investments of both an organization and employee. As a rule, the availability of the share of an employee's expenditures in overall expenditures for IPI creation increases the market cost of a product, which should be accounted for in planning production volume [**Błąd! Nie można odnaleźć źródła odwołania.**, p.123].

In a third stage, it is necessary to calculate the sums of anticipated earnings from IPI selling in royalty form, using the following formula:

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

$$P_R = \sum_{i=1}^t c_i \cdot q_i \cdot \frac{R}{100}, \quad (8)$$

Where:

P_R – anticipated royalty income (the fixed portion of sales value);

c_i – IPI market cost in the year (i) (with regard to price indexation);

q_i – quantity traded in the year (i);

R – royalty rate, % (remuneration of an invention stipulated in a contract with an organization, based on existing standard rates in a definite industry and for a definite type of products;

t – period of contract validity (IPI useful life).

In a fourth stage, it is necessary to calculate an employee's income from royalty payment measured as the difference between royalty income and an employee's expenditures:

$$NP = PR - ET, \quad (9)$$

Where NP – earnings from royalty payment (total net profit (P)). This can be paid to an employee as a lump sum; nevertheless, the necessity to pay a significant amount prior to the receipt of real profit as well as a higher risk related to the IPI commercialization result in an organization's possible refusal to make a lump-sum payment to its employee. Also, an employee has no access to the information on implementing his invention/know-how). A more preferable payment is periodical discounted cash flows calculated as follows:

$$PR_i = NP_i \cdot D_i, \quad (10)$$

Where PR_i – profit of an employee given as royalty in the year (i);

D_i – coefficient of discounting in the year (i) calculated with the following formula:

$$D_i = \frac{1}{(1 + 0.01 \cdot r)^i}, \quad (11)$$

Where r – discount rate in % measured via the cumulative method:

$$r = Rf + Rp, \quad (12)$$

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

R_f – risk-free rate of return for an innovative project, which is usually given as the safe-deposit rate of the most reliable banks;

R_p – premium paid by an organization for IPI implementation and commercialization risks (from 1 to 10%);

The quantitative evaluation of the component (R_p) shows the probability of both unfavorable dynamics in the innovation process and negative results of innovation activity; and this is determined via the expert approach as the sum of probabilities in each group of risk factors:

- Scientific and technical risks;
- Project regulatory support risks;
- Commercial offer risks;
- Entrepreneurial activity risks that deal with the probability of lower earnings insufficient to defray entrepreneurial expenses.

Thus, in formula (5) the component (P) is either a single lump-sum payment or a series of payments to an employee as royalty over the period (t).

The coefficient (G_{IA})

Formula (5) contains the indexes characterizing the value of an employee as an organization's hired worker and as an owner of intellectual capital (P , IB). We suppose that the ratio of these two index groups allows defining the efficiency of an employee's innovation activity:

$$K = \frac{P + IB}{S + ED}, \quad (13)$$

If this value exceeds 1, this means that payments to an employee as to the owner of intellectual capital are higher than expenses for this employee as for a hired worker, thus his innovation activity being efficient.

Conclusions

Thus, the valuation of an employee's intellectual capital is associated with element-by-element monetary evaluation of his innovation results by means of combining the cost model and the income model accounting for innovation activity risks as well as intellectual and attestation characteristics.

This model should be used for determining effects from an employee's intellectual and innovation activity and, as a result, for proving stimulating bonuses, and for taking management decisions aimed to increase both the

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

efficiency of an employee's performance and development as well as to develop the system of his motivation. Moreover, the model is recommended for use in further valuation of an organization's intellectual human capital. The development of methodology and intellectual human capital valuation practice at the micro-level is oriented to the possibility to implement his intellectual potential by each employee, to provide a growth of innovation activity to an organization, thus improving a personal competitive power in the conditions of knowledge economy. At the mezzo-level, this method allows creating a scientific and methodological basis for the development and monitoring of programs to increase the quality of human capital performance in the regional system of innovation and to encourage small and medium-sized businesses in innovative activity.

Global Competitiveness and Economic Growth: A One-Way or Two-Way Relationship?

JEL Classification: *O40; O57; C23; F43*

Keywords: *Global Competitiveness Index; economic growth; panel Granger causality test*

Abstract: The Global Competitiveness Index is treated as a standard to measure the competitiveness of countries. Leaders look at it to make policy and resource allocation decisions because global competitiveness is expected to be related to economic growth. However, studies which analyze the empirical relationship between these two economic categories are very rare. It is still an open question in the literature whether economic growth can be used to predict future global competitiveness or the other way round. This paper empirically tests the relationship between the GCI and the economic growth rate by using a panel Granger causality analysis based on annual data for 114 countries divided into five groups by income criteria and covering the period 2006-2014. We confirm a strong unidirectional causality among the countries analyzed, i.e. GDP growth causes global competitiveness. Additionally, we find that the GCI is not successful in predicting economic growth for the majority of the 114 counties, with the exception of few large economies such as China, India, the United States and Russia.

Introduction

National competitiveness is one of the most central preoccupations for both advanced and developing countries (Porter, 1990) and "many policy makers express serious concerns about it" (Lall, 2001, p.1501). Much has already been written about competitiveness, and today many economic phenomena are described as competitive or non-competitive issues. Nevertheless, both the definition and the analysis of the competitiveness of an economy still pose many problems. First of all, one may be surprised not only by the multitude of definitions of national competitiveness but also by the diversity of approaches to determining what competitiveness actually is at the macro level. Even such an expert as M. Porter in his book "The competitiveness advantage of nations" does not define it explicitly, despite using the term very often (Olczyk, 2008). Berger identifies four main but very different theoretical constructs for national competitiveness, and they show large divergences. National competitiveness can be understood as the "ability of a nation to sell its goods to another nation", as the "ability of a nation to earn", as the "ability to adjust to changes in the external environment" and as the "national ability to attract scarce mobile resources" (Berger, 2008, pp. 378-392). Each approach implies the use of different indicators to assess country competitiveness.

According to Berger, another fifth concept of national competitiveness exists based on Porter's diamond model and its extended versions. Porter proposed a national diamond model, which identifies four classes of country attributes that determine national competitive advantage: factor conditions; demand conditions; related and supporting industries; and company strategy, structure and rivalry. He also indicates two other factors – government policy and chance (exogenous shocks) – that support the system of national competitiveness but do not create it (Porter, 1990). A key feature of Porter's proposal is that it integrates many different theories into the one concept, i.e. "factor conditions" relate to classical/neoclassical economics, "demand conditions" are connected to product cycle theory and Rostow growth theory, "related and supporting companies" derives from polarization theory and Marshall's industrial districts, and "firm strategy, structure and rivalry" refer to Schumpeter's works. Although the diamond model has been widely applied to studying the competitiveness of different countries, it has met with some criticism. According to Smit (2010, pp.105-130), the weak aspects of Porter's model have been pointed out both by scholars of management (Dunning, 1992; Dunning, 1993; Rugman, 1990; Rugman,

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

1991; Rugman and Verbeke, 1993) and economics (Waverman, 1995; Boltho, 1996; Davies and Ellis, 2000). Management experts accuse Porter of not considering multinational activities in his model, so Dunning (1993) extended Porter's original model by adding the following variables: foreign direct investment, government policies and pro-competitive policies. In turn, economists indicate a lack of *ex ante* prediction ability as a weak point of the model.

Nevertheless, the national diamond model was a breakthrough in the study of country competitiveness due to Porter and his followers' complex approach to macro-competitiveness analysis. It opened a discussion about the determinants and indicators of national competitiveness and became a basis for the creation of two leading indices of country competitiveness: that published in the World Economic Forum Report and that in the IMD's World Competitiveness Yearbook. In particular, the methodology used by the World Economic Forum (WEF) is very closely related to Porter's diamond model. It defines country competitiveness as the "*set of institutions, policies, and factors that determine the level of productivity of a country*" (Schwab, 2015, p.4). Porter also states that competitiveness has a set of microeconomic determinants (like, e.g., firm strategies, rivalry), macroeconomic conditions (like, e.g., demand) and factors determining government power. Thus, the methodology proposed by the WEF is based on the assumption that competitiveness is such a multidimensional phenomena that the most appropriate approach to assessing country competitiveness as a single indicator involves a compilation of many individual competitiveness indicators.

The WEF constructs a Growth Competitiveness Index (GCI) which includes a weighted average of 112 different components. These components are grouped into 12 pillars of competitiveness and each of them measures a different aspect of it. They are: (1) institutions, (2) infrastructure, (3) macroeconomic environment, (4) health and primary education, (5) higher education and training, (6) goods market efficiency, (7) labour market efficiency, (8) financial market development, (9) technological readiness, (10) market size, (11) business sophistication, and (12) innovation (Global Competitiveness Report 2015-2014, pp. 4-8). These 12 pillars are organized into three groups: basic requirements (pillars 1-4), efficiency enhancers (pillars 5-10) and innovation and sophistication factors (pillars 11-12). The WEF puts a different weight on each of the three groups and divides countries according to their stage of development, because developing countries are competitive in the field of basic requirements, the competi-

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

tiveness of emerging countries is based on the efficiency enhancers, and at least most developed countries compete thanks to their innovations.

Although the GCI is one of the most accepted and recognized indicators of national competitiveness in the literature, it is not exempt from criticism. Lall (2001, pp.1501-1525) indicates many methodological, quantitative and analytical problems, and dubs the index "misleading" due to its arbitrary weighting of variables and use of subjective indicators. Other researchers also question the high correlation among its pillars (Carvalho et al., 2012, pp. 421-434), the lack of a good theoretical basis for the selection of its variables (Berger & Bristow, 2009, pp. 378-392), and even methodological errors and data manipulation which may lead to undesirable results (Freudenberg, 2003, pp. 1-29). Van Stel indicates two of the most serious problems with the GCI (Van Stel et al., 2005, pp. 311-321): the index is not even stable over short time periods for developed economies (the USA was ranked 6th in 2007 and 1st in 2008); and it is not successful in predicting short- and long-term economic growth because it combines so many other variables, such as entrepreneurial activity (Xia et al., p. 47). However, the authors of the latest Global Competitiveness Report state that "the concept of competitiveness thus involves static and dynamic competitiveness and ... can explain an economy's growth potential" (Schwab, 2015, p.4). Because studies which evaluate the validity of the GCI for economic growth prediction are very rare, the aim of this paper consists in empirically evaluating the effect of global competitiveness on economic growth. In addition, we have decided to go further and check the predictive validity of the inverse relationship, i.e. whether economic growth predicts global competitiveness.

The paper is organized as follows. The next section contains a theoretical discussion on the possible impact of global competitiveness on economic growth and *vice versa*. Section 3 opens up the methodological part of the paper, i.e. it introduces the data and the panel Granger causality test methodology. Section 4 presents the results of the analysis and the last section gives our conclusions.

**Economic growth driven by the Global Competitiveness Index
or *vice versa* – theoretical aspects**

As mentioned, the WEF-constructed Growth Competitiveness Index (GCI) includes a weighted average of 112 different components grouped into 12 pillars of competitiveness, and the pillars are classified into three compo-

Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

nents: "factors", which determine a better environment for high productivity (Bai, 2009, pp. 257-275), "efficiency", which is connected with the labour, goods and services markets and their influence on production efficiency (Qin et al., 2009, pp. 291-315), and "innovations", which are necessary for growth sustainability (Koong et al., 2011, pp. 181-196). In reality, the majority of these pillars are taken from six main economic theories: classical, neoclassical and Keynesian economic theory, development economics, new trade theory, and the most important new economic growth theory – endogenous growth theory (see Table1). Since the GCI measures "the level of productivity of an economy, which determines its long-term growth potential" (Schwab, 2015, Appendix A), endogenous growth theory becomes more significant.

Table 6. Keys driving factors of competitiveness in main economic theories

Theory	Keys driving factors of competitiveness
Classical	<ul style="list-style-type: none"> • investment in capital (i.e. improved technology) enhances the division of labour (specialization) and, hence, raises productivity. • trade (moving from autarky to free trade) provides an engine for growth (static gains from trade).
Neoclassical	<ul style="list-style-type: none"> • trade (moving from autarky to free trade) provides an engine for growth (static gains from trade).
Keynesian economic theory	<ul style="list-style-type: none"> • capital intensity. • investment . • government spending, such as investment in the public domain and subsidies/tax cuts for enterprises.
Development economics	<ul style="list-style-type: none"> • moving from agriculture to higher value added sectors. • openness to trade. • foreign direct investment (FDI). • (foreign) development funds.
New economic growth theory	<ul style="list-style-type: none"> • R&D expenditure. • innovativeness (patents). • education level . • spending on investment in human capital (schooling, training). • effective dissemination of knowledge (knowledge centres).
New trade theory	<p>Factors influencing "first mover" advantage, e.g.</p> <ul style="list-style-type: none"> • skilled labour • specialized infrastructure • networks of suppliers • localized technologies

Endogenous growth is long-run economic growth at a rate determined by forces that are internal to the economic system, and particularly those forces governing the opportunities and incentives to create technological

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

knowledge. This theory attempts to explain the sources of productivity growth and emphasizes the crucial roles of human capital (Lucas 1998), innovations (Romer, 1990; Aghion & Howitt, 1992), infrastructure (Barro, 1990), institutions (Romer, 1986), competition and openness (Grosman & Helpman, 1991). In Table 2, the determinants of selected endogenous growth models are assigned to some of the pillars of the GCI.

Table 7. The inspiration for the pillars of global competitiveness from models of endogenous growth

Pillars of competitiveness	Pillar 1	Pillar 2	Pillars
Endogenous growth model inspirations	Romer (1986): institutions Barro (1990): infrastructure Lucas (1988): health and primary education	Lucas (1988): health and primary education Pagano (1993): sophistication of financial markets Grosman and Helpman (1991): opening to technology and size of the market	Romer (1990) and Aghion et Howitt (1992): sophistication of firms and innovations

Source: Ben Amar, Hamdi (2012, p. 126).

Because the determinants of growth in endogenous growth theory are often simultaneously key drivers in the GCI pillars, we decide to check the following hypothesis: the GDP growth rate can predict the Global Competitiveness Index.

We also decide to verify the opposite hypothesis: that the GCI can be a good predictor of GDP growth. The authors of older versions of the Global Competitiveness Report themselves claimed that the GCI can "determine the aggregate growth rates of an economy" (Lopez-Claros et al. 2007, p. 3). In the latest WEF Report on Global Competitiveness we can also find the argument that "a more competitive economy is one that likely grows faster over time" (Schwab, 2015, p.4).

Data and Methodology

The empirical analysis presented in this paper is based on the Global Competitiveness Index Historical Dataset for 114 countries over the years 2005-2014. The historical data in the dataset are not updated but correspond to the data that was originally published in nine past editions of the WEF Global Competitiveness Report¹. The list of countries analysed is

¹ editions: 2006-2007, 2007-2008, 2008-2009, 2009-2010, 2010-2011, 2011-2012, 2012-2013, 2013-2014, 2014-215

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

limited from 144 to 114 due to either a lack of a Global Competitiveness Index or of GDP PPP values for some countries in part of the period analysed.

We use two variables: the Global Competitiveness Index (GCI) and the GDP PPP annual growth rate. GDP PPP is gross domestic product converted to international dollars using purchasing power parity rates². GDP is the sum of gross value added by all resident producers in the economy plus any product taxes and minus any subsidies not included in the value of the products (World Bank, 2015). An international dollar has the same purchasing power over GDP as the U.S. dollar has in the United States. The data are in current international dollars. For most economies, the PPP figures are either extrapolated from the 2011 International Comparison Program (ICP) benchmark estimates or else imputed using a statistical model based on the 2011 ICP report³.

The GCI is a composite competitiveness index combining "hard data" on various national characteristics and "soft data" compiled from the WEF's annual Executive Opinion Survey. To ease the calculation of indexes, the WEF converts all hard data items onto a 1-7 scale using a min-max transformation⁴. The theoretical maximum of GCI is 7. Computation of it is based on successive aggregations of scores from the indicator level. At the most disaggregated level, an arithmetic mean within a category is used to aggregate the individual indicators, while for the higher aggregation levels fixed weights for each category are applied (Schwab 2015, Appendix B). At the highest aggregation level – i.e. at the three sub-indices level – the weights applied are not fixed and depend on each country's stage of development.

To analyze the relationship between global competitiveness and the economic growth rate, we decide to divide all 114 economies into homogeneous groups according to their gross national income (GNI) per capita⁵,

² The Purchasing Power Parity (PPP) between two countries is the rate at which the currency of one country needs to be converted into that of the second country to ensure that a given amount of the first country's currency will purchase the same volume of goods and services in the second country as it does in the first.

³ The International Comparisons Program (ICP) is a global statistical initiative that produces internationally comparable Purchasing Power Parity (PPP) estimates. See http://siteresources.worldbank.org/ICPEXT/Resources/ICP_2011.html.

⁴
$$\text{min-max formula} = 6 \cdot \frac{\text{country value} - \text{sample minimum}}{\text{sample maximum} - \text{sample minimum}} + 1$$

⁵ As of 1 July 2014, low-income economies are defined as those with a GNI per capita, calculated using the *World Bank Atlas* method, of \$1,045 or less in 2013; middle-income

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

calculated using the World Bank Atlas method⁶. The purpose of the Atlas conversion is to reduce the impact of exchange rate fluctuations in the cross-country comparison of national incomes. Each of the economies analysed belongs to one of five groups: low-income, lower-middle-income, upper-middle-income, high-income non-OECD countries, and high-income OECD countries.

In this paper, the relationship described above is assessed by means of a Granger causality test. In accordance with Granger (1969), causality means that a series x can be said to cause a series y if and only if the expectation of y given the history of x differs from the unconditional expectation of y :

$$E(y | y_{y-k}, x_{t-k}) \neq E(y | y_{t-k}). \quad (1)$$

The question is whether lagged values of series x bring additional information to predict series y or if series y can be better predicted only using its past values.

For T periods and N individuals, the time-stationary VAR model adapted to a panel data context is as follows:

$$y_{i,t} = \sum_{k=1}^p \gamma^{(k)} y_{i,t-k} + \sum_{k=0}^p \beta_i^{(k)} x_{i,t-k} + v_{i,t}, \quad i=1,\dots,N, \quad t=1,\dots,T, \quad (2)$$

where v_{it} is the sum of individual effects α_i and random disturbances ε_{it} .

The concept of Granger causality for panel data can be considered in two ways. The first approach, proposed by Holtz-Eakin et al. (1985, p.12), uses Chamberlain's investigation (1984, pp. 1247-1318) and allows all of the parameters in regression two to be time-varying. Following this, Hsiao (1989, pp.565-587) and in a similar way Weinhold (1996, pp.163-175),

economies are those with a GNI per capita of more than \$1,045 but less than \$12,746; high-income economies are those with a GNI per capita of \$12,746 or more. Lower-middle-income and upper-middle-income economies are separated at a GNI per capita of \$4,125. See <http://data.worldbank.org/news/2015-country-classifications>.

⁶ The Atlas conversion factor for any year is the average of a country's exchange rate for that year and its exchange rates for the two preceding years, adjusted for the difference between the rate of inflation in the country and international inflation. <https://datahelpdesk.worldbank.org/knowledgebase/articles/378832-what-is-the-world-bank-atlas-method>.

Weinhold (1999) and Nair-Reichert & Weinhold (2001, pp.193-171) use a Mixed Fixed and Random Model to evaluate Granger causality. A different approach is used by Hurlin & Venet (2001, pp.3-19), who assume that the parameters of the regression are fixed and propose a wide procedure for testing causality. In this paper, the Hurlin and Venet approach is applied.

When using panel data, we expect heterogeneity between individuals to be for two reasons. The first reason is a natural cross-sectional difference between panel units. This type of heterogeneity is taken into account by separating individual fixed effects α_i from random disturbances v_{it} .

Applying this to equation 2, we treat v_{it} as the sum of individual effects α_i and random disturbances ε_{it} and impose the following assumptions on α_i and ε_{it} :

$$\begin{aligned} \alpha_i &\sim IID(0, \sigma_\alpha^2), \quad \varepsilon_{it} \sim IID(0, \sigma_\varepsilon^2) \\ E(\alpha_i \varepsilon_{it}) &= 0 \\ E(\alpha_i \alpha_j) &= E(\varepsilon_{it} \varepsilon_{js}) = 0, \text{ for } i \neq j \text{ and } t \neq s \\ E(\alpha_i x_{it}) &= E(\varepsilon_{it} x_{it}) = 0. \end{aligned} \tag{3}$$

The second reason for heterogeneity among panel units follows from there being two subgroups within the whole group – a subgroup where causality between x and y exists ($\beta_i^{(k)} \neq 0$) and a subgroup where the causal relationship is not observed ($\beta_i^{(k)} = 0$). The assumptions concerning the model coefficients are as follows:

- the autoregressive parameters $\gamma^{(k)}$ and coefficient slopes $\beta_i^{(k)}$ are constant for all lags;
- the autoregressive coefficients $\gamma^{(k)}$ are identical for all individuals but the regression coefficient slopes $\beta_i^{(k)}$ may vary between individuals.

The strategy for testing Granger causality proposed by Hurlin & Venet (2001) is presented in Table 3.

The procedure consists of 3 steps. First, the Homogeneous Non-Causality (HNC) hypothesis is tested. When the null cannot be rejected, it means that no individual Granger causality is observed. Otherwise, the second step of the procedure is needed. This step consists in checking whether the group analysed is homogeneous or not. The last step allows the question of there being a subgroup of individuals for which causality is observed and a subgroup for which the causal relationship does not exist to be answered.

Results

The procedure for evaluating Granger causality is based on a time-stationary VAR model. For the purpose of evaluating unit-root presence we use two panel unit root tests: the Harris-Tzavalis test (Harris & Tzavalis, 1999, pp. 201-226) (HT) and the Im-Pesaran-Shin test (Im et al., 2003, pp. 53-74) (IPS), which are chosen in the light of the sample size. Additionally, in the HT test a small-sample adjustment to T is made. Both tests are applied for each of the five income groups: low-income countries (LI), lower-middle-income countries (LMI), upper-middle-income countries (UMI), high-income non-OECD countries (HnOECD) and high-income OECD countries (HOECD). The results of the tests are presented in Table 4.

Source: Own preparation

For GDP growth, both the Harris-Tzavalis and the IPS test allow the null hypothesis that the GDP growth time series contains a unit root to be rejected. For the Global Competitiveness Index, the IPS test is significant for all the groups as well, but the HT test for UMI and HnOECD countries does not reject the null.

Finally, we can treat both variables as time-stationary and start the procedure for Granger causality evaluation, which is based on two regressions, estimated for each income group separately:

$$\Delta GDP_{i,t} = \sum_{k=1}^p \gamma^{(k)} \Delta GDP_{i,t-k} + \sum_{k=0}^p \beta_i^{(k)} GCI_{i,t-k} + v_{i,t}, \quad (4)$$

$$GCI_{i,t} = \sum_{k=1}^p \gamma^{(k)} GCI_{i,t-k} + \sum_{k=0}^p \beta_i^{(k)} \Delta GDP_{i,t-k} + v_{i,t} . \quad (5)$$

Due to the shortness of the time series, the number of lags in regressions 4 and 5 are limited to k=2. A LSDV estimator is used to estimate the above models⁷.

⁷ As Hurlin & Venet (2001) note, the results of F statistics obtained with consistent estimators like the Anderson and Hsiao estimator or the GMM estimator are lower than those with a FE estimator, but in fact the differences are relatively small. In our case, it means that we will have an upward bias and we should not reject the null in some cases.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

Following Table 3, first we explore whether in the homogeneous sample we can observe bidirectional causality, unidirectional causality or we cannot reject the null. Taking each income group individually, we can strongly reject the homogeneous non-causality hypothesis (Table 5). A causal relationship from the Global Competitiveness Index to GDP growth exists and it also works the other way round for all the lags tested apart from the relation $GCI \rightarrow \Delta GDP$ assessed for high-income non-OECD countries and the first lag.

Source: Own preparation

The next step is to examine whether the relationship between the competitiveness measure and GDP changes is strictly homogeneous or not in the countries which belong to each income group. The results are reported in Table 6. We reject the Homogeneous Causality hypothesis, which is in line with our expectations. The pattern of rejection is similar to the first step. As previously, for the relation from GCI to GDP growth with one lag for HnOECD countries we cannot reject the HC hypothesis. In addition, it cannot be rejected for the second lag and the relation in the opposite direction. Except for these cases, in general we observe a differentiation in respect of causality according to the group that the countries analysed belong to.

Given the rejection of the HC hypothesis, the HENC hypothesis should be tested. We are interested in the subgroup of countries among each income group for which the causal relationship does not exist, neither from GDP growth to GCI nor from GCI to GDP growth, both for which we can observe a one-way relationship and for which the relationship is bidirectional. The results are reported in Tables 7,8,9,10 and 11 for LI countries, LMI countries, UMI countries, HnOECD countries and HOECD countries respectively.

The results suggest that regardless of the income group, the relationship from GDP growth to the Global Competitiveness Index is more often observed than the opposite one. It is interesting that only for large economies like India, China, Russia, Germany, the United Kingdom and the United States there is a strong significant influence of the GCI on the growth rate of GDP. For the majority of these countries the relationship is unidirectional only, but a two-way relationship between competitiveness and economic growth is observed for the United Kingdom and the United States.

In this research we use a LSDV estimator, which, in light of dynamic regression (2), has an upward bias in comparison with the Anderson-Hsiao estimator or the GMM estimator, but the values of the F statistics obtained for the countries mentioned above are large enough to reject the null.

Conclusions

This paper has tested whether the GCI is a reliable predictor of economic growth or whether the growth rate can be believed to predict the global competitiveness of a country. Our empirical study, first done at the country group level, indicates a quite strong bidirectional causality between the Global Competitiveness Index and the economic growth rate for all the lags tested. The exception is the group of high income non-OECD countries, where a relation from the GCI to GDP growth is significant for one lag and the opposite relation for the second lag only.

We have also examined the kind of causality. The results were in line with our expectations. All the groups analysed turned out to be heterogeneous.

The last step of our investigation was to assess the direction of the relationship between the GCI and the growth rate of GDP at the level of individual countries within each of the five groups of countries. The results of our estimations confirm that economic growth affects global competitiveness in the case of 70% of the countries in our sample. Most often this relationship exists among low income countries (in 12 out of 15 economies i.e.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

for 80% of the countries analysed). In turn, it is relatively rare among high-income non-OECD countries (in 53% of the countries).

Finally, we have confirmed that the GCI can predict the dynamic of a national economy, but only in some particular cases. We can support the WEF's claim that the GCI can "determine the aggregate growth rates of an economy" for the group of low-income countries. For almost 8 of the 15 countries with a lower income level we can justify the contribution of their global competitiveness level to their economic growth during the last decade. This evolution is probably due to a large number of economic reforms in these countries and good political stability, which affect capital accumulation and finally economic growth. Among the countries with a higher level of income, the causal relationship from the Global Competitiveness Index to GDP growth only exists for seven countries and they are all big economies, such as China, India, the United States and Russia.

Our study has a preliminary character, but its results imply that the WEF should refine GCI so that it can be a better predictor of economic growth.

**The Modern Challenges of Regional
Development and Socio-economic Potential of
Town Districts Belonging to North
Macro-region of Poland**

JEL Classification: *E62; E65; G28; H70; H71; H72; H76*

Keywords: *macroregion, town districts, development, socio-economic potential*

Abstract: Today, however, the concept of capital strongly focuses on intellectual capital, understood as the current or potential creative resource, or the increase in the wealth of a community. In this context, it is worth to examine the legitimacy of thesis about the expansive reality of Polish town districts.

Over the past 10 years, in North macro-region, there has been a significant improvement of characteristics relating to intellectual capital. At the same time, gross domestic product per capita in the macro-region annually increased its value. It is, therefore, necessary to maintain and multiply the rate of change in the socio-economic sphere, based on a coherent, harmonious and innovative development strategies, evaluating intellectual potential of the communities.

Introduction

Both in the context of identification of opportunities and threats to contemporary functioning organizations, and determining changes occurring in the management of any organization, capital, apart from land and work, is one of the three fundamental factors. During the evolution of this concept,

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

the concept of social capital originated. It stressed the role of individuals and social ties. (Wielka encyklopedia PWN, 2003, pp. 254; Antczak, 2013, pp. 21-; Sierocińska, 2011, pp. 69-86) Today, however, the concept of capital strongly focuses on intellectual capital, understood as the current or potential creative resource, or the increase in the wealth of an enterprise, community, or nation. (Erstad & Sefton-Green, 2012, pp. 146 -162; Herman, 2008, pp. 38-47)

The issue of intellectual capital, as well as the issue of the development of local communities, are relatively young fields of economics and spatial management, which do not yet have their own autonomous theory. Nonetheless, local communities play a crucial role in the economic and social system of the country. They are the places of concentration of the essential economic activity, initiating the potential associated with economic development, employment, and consumption patterns and all other aspects of specific economic reality.

Economic development, which is a part of the process of economic evolution means going higher and higher, on more diverse and more complex levels. It is the result of quantitative and qualitative progress and changes in the economic, social and natural systems. (Strzelecki (Ed.), 2008, p. 13) It is based in the space formed by political, economic, social and demographic events and processes, and phenomena concerning population are a special factor in economic transition because the population is the principal means and the ultimate goal of economic activity. As a result, human resources play a fundamental role in economic development. A special role in this field is played by human capital, which is the potential of knowledge, skills, health and vitality in the community. (Domański, 1993, p. 16) It is the knowledge and skills acquired by individuals as a consequence of investments in education and training affecting the quality of human resources, and the costs spent on the protection of health, environment, development of culture, etc. Therefore, human capital consists of all efforts and all the achievements of current and past generations of a given area. (Pająk (Ed.), 2009, p. 137) Thus, human capital development is a key explanatory variable in relation to competitiveness and regional differentials. At the same time, there is a feedback loop between human capital and the level of socio-economic development. (Nyce & Schieber, 2005, pp. 212 - 231; Moss et al., 2008, pp. 333-352)

Evaluation of the role of human capital (both social and intellectual) in the development of the region, can be done by means of two types of circumstances: demographic factors and social determinants. (Madej &

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

Zasadzki, 2001, pp. 117-118) Demographic determinants relate to population structure, diversification of capital resource and its development. Social conditions refer to the overall social infrastructure and living conditions of the population, forming a material basis for the services to meet the social, educational and cultural needs of the population. (Chirot, 2014, pp. 657-663)

Understanding the development of local communities, therefore, requires the analysis of all reciprocal characteristics. (Szewczuk et al., 2011, pp. 30-)

Interaction between entities within the specified district would be a catalyst to the formation of local governance, i.e. local communities involving particular entities of the territory. (Ostrom, 2008, pp. 61 – 110; Porras & Collins, 1996; Dolnicki (Ed.), 2014, pp. 44-57)

In turn, the notion of the region in economic sciences is seen in a triple sense: an important subject of research, object of cognition and object of action. The involvement of researchers in this complex area has created the theory of the region, which is assigned cognitive research and application functions. Within the research function a methodical basis for multidisciplinary research in regions and economic regional studies is created. Cognitive function deals with co-operation in the perception of the surrounding reality, in particular, individual regions. Finally, the application function concerns important strategic projects, that is making adjustments and proposals for a regional policy, as well as procedures for its correction. (Pop-Eleches & Tucker, 2013, pp. 45-68; Szewczuk et al., 2011, pp. 13-)

The subject of the article is based on the above classification. First, an appropriate research tool will be chosen, consisting of a set of statistical indexes. By using it we can prepare a characteristics of in the North macro-region. For the purposes of analysis, the national average size of indexes will also be set. However, the data relating to Warsaw were omitted, due to its specifics as the capital of Poland.¹ The conclusion of the article will be the applications, which can be further used in regional policy of the studied communities .

The test period includes past 10 years of the functioning of Polish local authorities, i.e. years 2004-2013.²

¹ The value of statistical indexes achieved by Warsaw, in each year, and in all respects, far exceed the index values by other cities grodzkie. Their omission raises the readability of both analytical comparisons and charts.

² For some indexes it was possible to get the data from shorter time periods.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

For the article subject structured in this way, the thesis is stated about expansive reality of Polish district communities. However, over the past 10 years, largely thanks to the funds from the EU, there has been a significant improvement in the values of characteristics relating to intellectual capital.³

Research area

The activities in the programming of Polish economic development policy for the period 2007-2013 and 2014-2020 have been oriented in such a way that the majority of priorities was and still is associated directly with the influence on the various dimensions of intellectual capital, and the other, indirectly to create favourable conditions for its accumulation. Noteworthy is the fact that the activities revolve around the dimensions that are particularly important in the relation between intellectual capital and competitiveness. They concern human and structural capital, but also care about the development of social capital. It is proved by the priorities concerning the innovation and growth of the economy, the efficient use of human resources and building social capital. What is more, these initiatives for the period 2007-2013 were the activities carried out within the framework of the two operational programmes: innovative economy and human capital, directly addressing the human and structural dimension of intellectual capital. In the period 2014-2020 a new instrument of European cohesion policy will be also used, which is the local development led by the community.

However, compared to other developed countries, Poland belongs to the countries with the lowest level of GDP per capita and the lowest values of the KI index (Knowledge Index), which can be treated as an approximate to intellectual capital.⁶ It is commented that the reasons are too slow dynamics of making technological upgrading, but also too slow process of changes on institutional, social and cultural level of Polish economy. The current level and structure of intellectual capital are a significant barrier to development.

When it comes to the Polish government structure, based on the concept of self-government contained in the European Charter of local self-

government⁷, at the local level there are three types of communities⁸: land districts⁹, town districts and municipalities¹⁰. The results of the statistical analysis of the situation of Polish local communities show their little optimistic financial situation. (Koza, 2013) However, town districts (i.e. the districts formed by big cities) display a very pro-development approach. This is the reason why these organisms will be subjected to further analysis in the following article. It is worth considering what factors have an impact on this state of affairs. (Strzelecki Z. (Ed.), 2008, p. 222)

Test area of this article will be a North macro-region of our country. It includes the voivodenships: Kuyavian-Pomeranian, Pomeranian and Warmian-Masurian. The macro-region is characterized by a high potential of dynamic economic development.

Research tool

Local and regional development is a relatively young field of economics and spatial management, which does not yet have its own autonomous theory. This specific type of activity, serving to develop and improve the organization of activities for spatial development as well as the structure and functioning of local government and social system, is based in the sphere of the theoretical considerations on a general theory of economic development or economic theory and the theory of spatial management. (Klasik, 1996, pp. 11-)

Research techniques relating to local communities can be divided into descriptive and quantitative ones. Descriptive test methods of territorial communities are generally characterized by a meticulous analysis of the facts. On the other hand, by using these methods, we get the results that are imprecise and incomparable in the wider scale, which create a large possibility of obtaining extremely subjective evaluations. Quantitative methods, on the other hand, do not have some of the shortcomings of descriptive methods. First of all, they give you very specific (measurable quantitatively), relatively unbiased results. This is, in turn, one of the conditions for the

18-19 June 2015, Economics and Finance**

application of the time-spatial comparisons, which are significant in the regional studies.

The research on the regularities occurring in mass phenomena and processes is done, in particular, with the use of taxonomic methods.

Taxonomic method was first taken from the field of anthropological research to zone farming systems by J. Fierich. (Fierich, 1957, pp. 73-100) The first successful attempt to zone agricultural production by means of taxonomic method became the impulse for the creation of many studies of this type. The most popular, taxonomic method of averages differences (named after its creator, Czekanowski) is based on connecting into groups the elements of a larger part. The elements that are connected, in comparison with other elements, are characterized by smaller average differences in terms of number of simultaneously included features. In other words, it is a classification of units (spatial in this case) of a group due to several intentionally selected characteristics. (Fajferek, 1966, p. 48; Bywalec & Rudnicki, 2002)

Taxonomy¹¹ is a discipline dealing with the rules and procedures of organization and classification. The taxonomic method is to group a set of elements of any nature into more statistically homogenous. (Kwiatkowski (Ed.), 2008, pp. 269-294; Czermińska, 2002, pp. 149-157)

In order to be able to use taxonomic method, two conditions must be met: first, the phenomenon chosen as a feature must be quantitatively measurable, secondly, reliable statistical data must be guaranteed that represent the values in the appropriate territorial section.

To assess the specificity of the intellectual capital of the local communities, based on the data from the Central Statistical Office¹², the following, grouped into subsets, characteristics will be applied:

1. Economic development:

- Investment in enterprises (current prices; without the entities with fewer than 9 employees) per capita in the working age population
- Entities of the national economy newly registered in REGON per 10 thousand inhabitants in the working-age population

¹¹ The term "taxonomy" is derived from two Greek words: taksis-"cleanings" + nomos, "law", "rule"(Kendall & Buckland, 1986, p. 194).

¹² Obtaining data from a local data Bank of the main statistical office, http://stat.gov.pl/bdl/app/wskazniki_zr, was completed on 25.11.2014, in addition to the index relating to the turnout in local elections, which didn't appeared on the website of the State Electoral Commission, <http://wybory2014.pkw.gov.pl/pl/frekwencja/wojewodztwa/index>.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

- The value of companies with foreign capital per capita in the working age population
- 2. Employment: Natural persons running their own business per 100 people in working age
- 3. Consumption Patterns: The number of passenger cars per 1000 inhabitants
- 4. Social inclusion :
 - The average gross monthly salary (entities of more than 9 employees)
 - Share of long-term unemployed (more than 1 year) in the total number of registered unemployed people
 - Registered unemployment rate
 - Graduates share (not working yet) in the total number of the unemployed
- 5. Demographics :
 - Birth rate per 1,000 population
 - The balance of migration for permanent residence of people in working age to 10 thousand inhabitants in working age
- 6. The adequacy of income during old age: Share of long-term unemployed (more than 1 year) in the 55-64 age group in the total number of all unemployed people aged 55-64
- 7. Health factors: Clinics per 10 thousand inhabitants
- 8. Climate change and energy: Electricity consumption per capita
- 9. Transport :
 - Length of public roads with hard surface per 100 sq. km
 - The length of cycle paths
- 10. Openness and participation :
 - The number of registered foundations, social associations and organizations per 10 thousand inhabitants
 - Turnout in the local elections
- 11. Economic instruments :
 - Funds from the European Union for the funding of programmes and projects of the EU obtained by the municipalities and districts per capita
 - Expenditure budgets of municipalities and districts for public debt to 1,000 PLN of total revenue budgets of municipalities and districts
 - Share of capital expenditure of municipalities and districts in total expenditure.

These characteristics allow to estimate the level of socio-economic development of local communities. (Ostrom, 1998, pp. 1 – 22; Woźniak (Ed.),

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

2014, pp. 276-295; Woźniak (Ed.), 2013, pp. 331-; Ranking miast powiatowych, 2014)

To describe the statistical structure of the above characteristics of the local communities will be used such measures as the arithmetic mean of the values achieved in individual years, dynamics chain indices, counted annually, and geometric mean presenting the increase in the values in the last year compared to the first year. (Forlicz (Ed.), 2008, pp. 219-232; Zeliaś, 2000, pp. 37-77)

Selected analytical methods allow for reliable insight into development processes. (Strzelecki, 2008, p. 15, 39) The above measurements, understood statistically, are relative numbers characterizing the alterations in the level of the phenomena occurring in a given time, i.e. indexes. (Timofiejuk et al., 1997, pp. 176-178; Nowak (Ed.), 1970, pp. 247-)

Taking into account the time (Sierpińska & Jachna, 1997, p. 17) , which will apply to the analysis, it will be a retrospective analysis (ex post), containing an assessment of the results of the actions taken in the past, which is the starting point for the current and future objectives.

Due to the established test method (Dylewski et al., 2004, p. 14), the author has chosen an analysis based on the comprehensive evaluation of reality from the point of view of the connections and dependencies between economic phenomena. It contains a comprehensive look at the activities of an enterprise and is a tool for understanding and evaluation of economic phenomena. It provides a structured observation, expressed in terms of points, along with the cause and effect relationships between these phenomena.

Analytical research will end with the presentation of results, in numerical, graphic and descriptive form. Numeric form will help sort out the information about the investigated phenomena in time and in space.¹³ Graphic form will show the changes observed in the studied characteristics by means of radar charts.¹⁴ Finally, the descriptive form will serve to express assessments and opinions and formulate diagnoses and proposals.

Socio-economic development

The level of development of the local community is the starting point to the characteristics of the factors supporting the construction of sustainable

¹³ Because of the editorial requirements, the figures will not be presented in the body of the article.

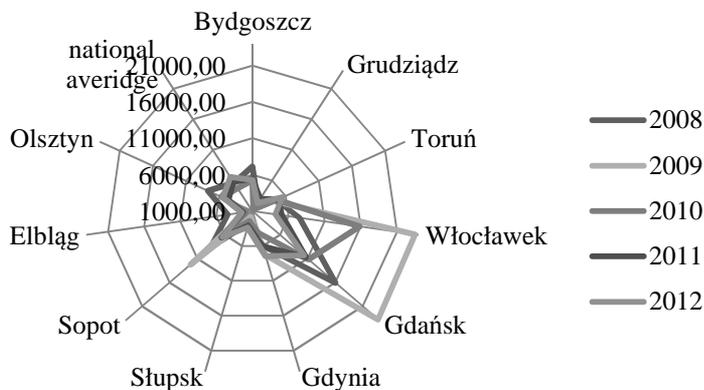

¹⁴ In the body of the article will be placed only the most charts.

development. Development is a fundamental concept in the functioning of economies. A high level of economic development usually creates the conditions to ensure a higher level of life of the inhabitants, understood as the degree to which the needs of all kinds are satisfied with goods, including material ones, cultural, educational, related to health and security. At the same time, economic development may be accompanied by a range of negative effects, such as environmental degradation, high levels of pollution. In addition, one of the key tasks of sustainable development is smooth economic development of all regions. (Grabowski et al., 2013, pp. 3-55; and Pawłowska, 2013, pp. 17-70)

In the North macro-region during the period of research when it comes to investment per capita in the working age population, after the initial decline, there was an annual growing trend, which was visible especially in Gdynia, Włocławek and Gdańsk.

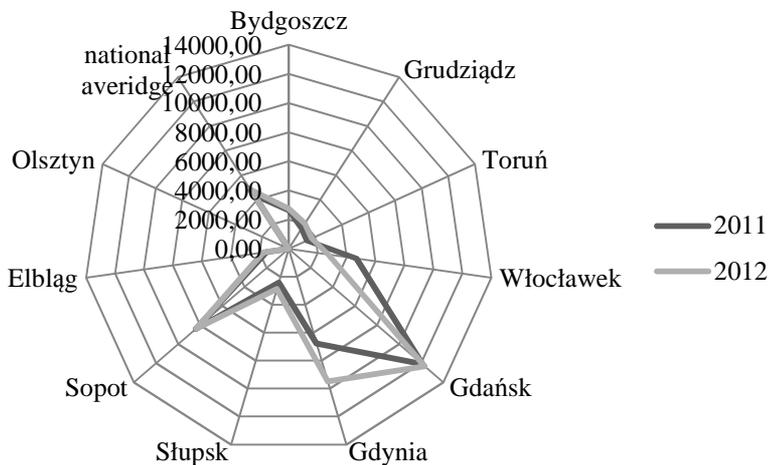

When it comes to the number of entities of the national economy registered in REGON, in most cities there was a growing trend. Similarly, the value of companies with a foreign capital, calculated per capita in the working age population, every year was getting higher. In this context, the outstanding results were achieved by Gdynia and Gdańsk.

Figure 1. Investment in companies per capita in the working age population

Source: own elaboration based on data from local data bank of the main statistical office, http://stat.gov.pl/bdl/app/wskazniki_zr

Figure 2. The value of foreign capital companies per capita in the working-age population

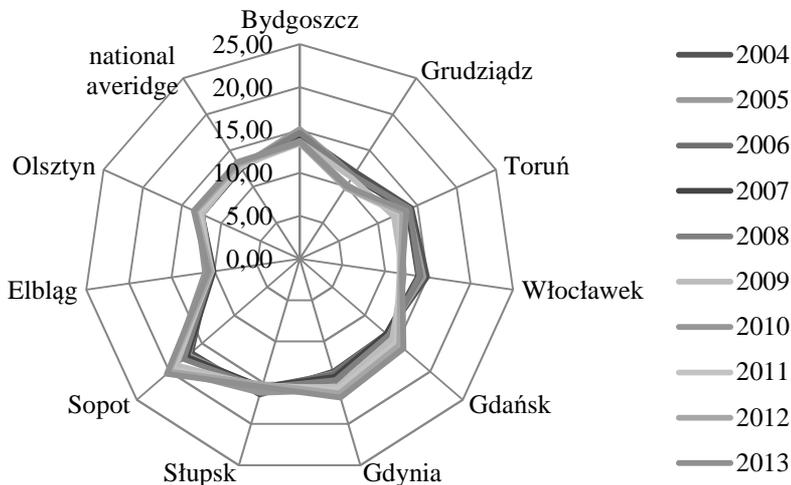

Source: as above.

Employment

An important factor in the development of the regions are labour resources and related human capital. In sustainable development it is one of the elements of interrelated conditions for wealth creation, alongside traditional resources as land and capital, as well as factors, such as, the level of resources and the environment. One of the objectives of sustainable economics is employment for all people in working age. (Markowski, 2009, p. 13; Kwiatkowski (Ed.), 2008, pp. 25-38; Grzega, 2012, pp. 220-268)

Employment in each of the cities of North macro-region, is annually increasing. This was especially visible in Sopot.

Figure 3. Natural persons running their own business per 100 inhabitants in working age

Source: as above.

Sustainable consumption and production

Changing production and consumption patterns towards sustainable, as well as the promotion of such behavior is one of the key challenges of the modern world. Separating economic growth from environmental degradation is a condition for sustainable development. (Markowski, 2009, p. 13; Kwiatkowski (Ed.), 2008, pp. 25-38 and Grzega, 2012, pp. 220-268)

The determinant of the above changes is the number of passenger cars per 1000 inhabitants. In the North macro-region, this quantifier is every year higher.

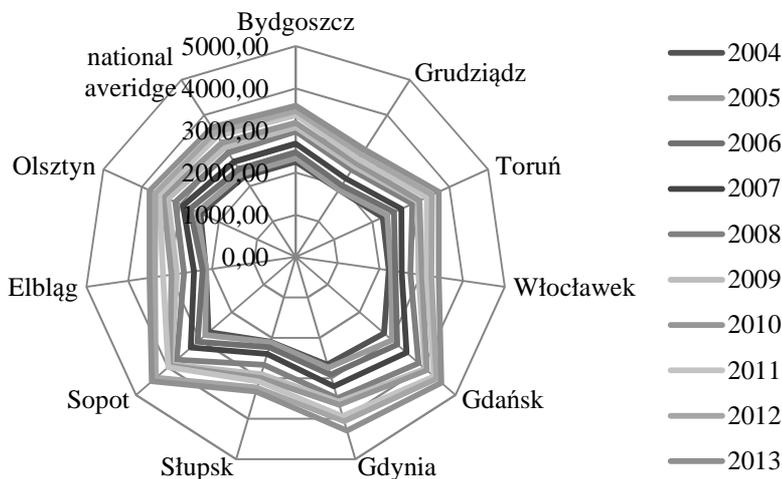

Social inclusion

Exclusion and social inequality is a situation that prevents (or at least makes it difficult) an individual or group from performing social roles (family, professional, civil, social), making the use of public goods and social infrastructure, collecting resources and earning income in a worthy manner. The problem of social exclusion is a major barrier to economic

growth and sustainable development. On the contrary, the concept of social inclusion implies the creation of a society based on social inclusion, taking into account the solidarity between the generations and within the generations, as well as to ensure the improvement of the quality of life of citizens, which is the basis of social welfare. (Lew-Starowicz & Lorecka, 2013, p. 16; Kotowska, 2014, CD-ROM)

The index that provides statistical information in this field is the average gross monthly salary. As far as the cities of the North macro-region are concerned, in the last decade, as in all Polish cities, every year there was an increase in this value. In particular, there was the Tricity, including Gdańsk, Gdynia and Sopot.

Figure 4. The average gross monthly salary (entities of more than 9 people)

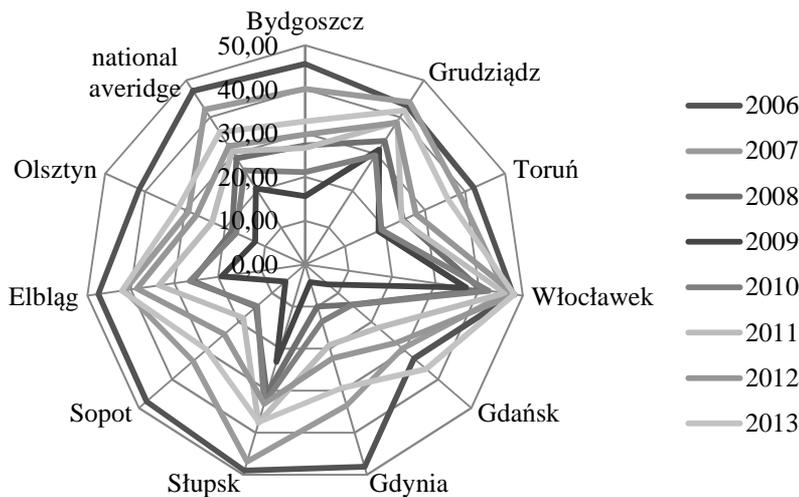

Source: as above.

Access to the labour market in the context of social inclusion also means that every citizen showing willingness to work should be able to find a job corresponding to their professional qualifications. The place occupied on the labour market decides not only about material, but also social status. (Barteczek & Rączaszek (Ed.), 2014, p. 34; and Kotowska, 2014, CD-ROM; Pająk, 2009, pp. 19-32)

In the macro-region, the share of long-term unemployed increases every year, even though to a less extent than in other town districts in our coun-

try. Similarly, the registered unemployment rate increased every year. A positive sign is that the share of unemployed graduates in general was decreasing over time but that was the effect of the high rate of migration of young people abroad.

Figure 5. Share of long-term unemployed (more than 1 year) in the total registered unemployed

Source: as above.

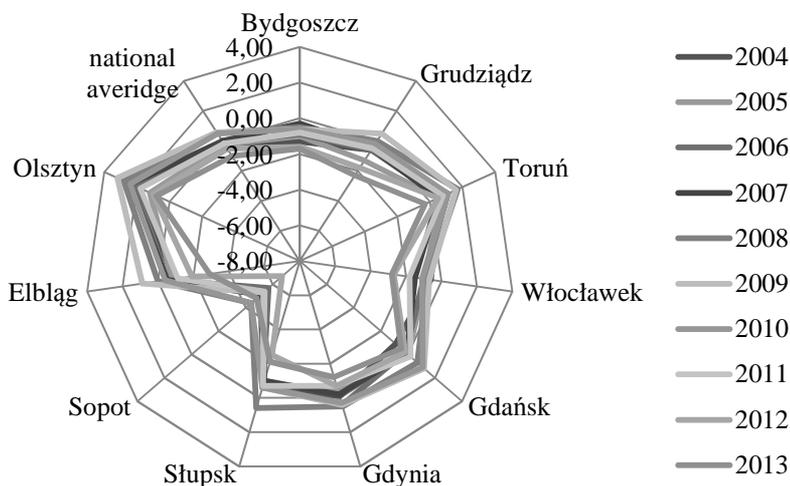

Demographic changes

In Poland there is a further intensification of the process of aging of the population. This situation may result from more conscious family planning, improved availability and quality of medical services, improvement of the material situation of the population and the pursuit of a healthier lifestyle. Progressive aging process requires planning and organizing such activities of social welfare which will meet a variety of needs of people belonging to the older age group and provide them with adequate health care and access to the labour market. It is a big challenge for the social policy of the state in maintaining the sustainable level of public finances. Demographic changes are therefore of vital importance for economic and social development. (Pająk (Ed.), 2009, p. 173; Gwiazda, 2011, p. 56-67) At the same time, fair distribution of income, solidarity between generations, as well as the in-

crease in the level of life, reduction of poverty and social exclusion among older people are classified as priority objectives of sustainable development. (Grzega, 2012, pp. 7-158) The primary gauge group of demographic changes are those indicators that serve to diagnose the situation and the trends of aging in the population, which is influenced by many factors including, among others, the level of total fertility rate, life expectancy, the phenomenon of migration.

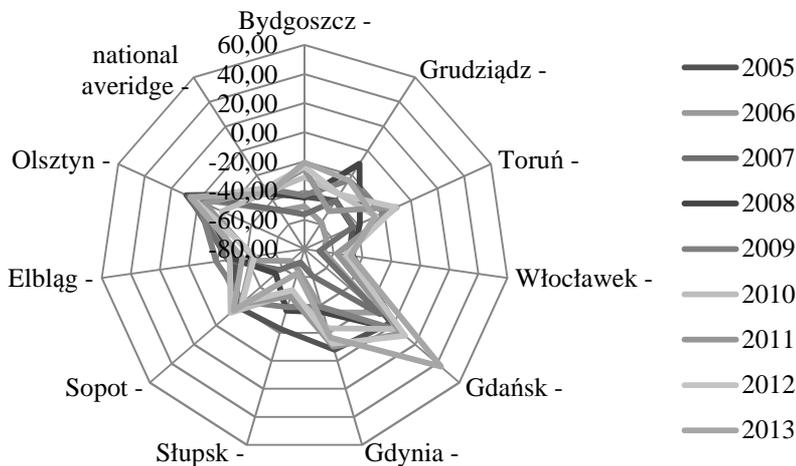

In the North macro-region during the period considered, the birth rate was definitely decreasing, especially in Sopot, and there was a positive balance of migration. At the same time, with the exception of Włocławek and Gdynia, the share of the long-term unemployed in the 55-64 age group in a total number of the unemployed people aged 55-64 increased.

Figure 6. Birth rate per 1,000 population

Source: as above.

Figure 7. The balance of migration for permanent residence of people in working age to 10 thousand inhabitants in working age

Source: as above.

Public health

Access to health care and the health status of the population are included in the basic quality of life factors, apart from, among others, material resources, a feeling of security, recreational activities, etc. Links between health and the concept of sustainable development are multidimensional and manifest themselves in many ways, among which may be mentioned, in addition to improving the quality of life, the effectiveness and the costs of the functioning of the economy and the impact of the environment on the health of the public. Health factors were taken into account by the impact of environment and the environment on the health status of the population and the access to health care. Even low levels of long-term exposure to complex mixtures of pollutants in the air, water, soil, consumer products and buildings can have a significant impact on health. The factor that affects health is also working conditions associated with: working environment, discomfort and mechanical factors. (Pasowicz (Ed.), 2013, pp. 15-84)

The number of clinics per 10 thousand residents was nearly constant in the cities of the North macro-region.

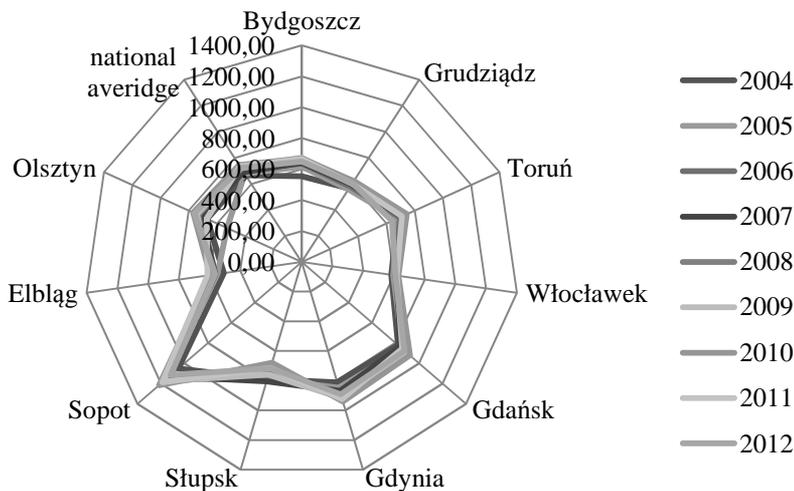

Energy demand

Limiting climate change, the cost of these changes and the negative effects on the environment and society is the primary determining factor for preserving our planet for future generations.

The demand for energy, growing with the development of civilization, which is running out of its traditional resources, mainly fossil fuels (coal, oil, natural gas), accompanied by environmental pollution, increases consumption, 2014, t. 1, pp. 11-; t. 2, pp. 34-; Sułkowski (Ed.), 2011, pp. 25-66; Swora & Woszczyk (Ed.), 2011, pp. 23-)

Electricity consumption per capita in the North counted during the period had been declining. Particularly positive results in this regard achieved Sopot.

Figure 8. Electricity consumption per capita

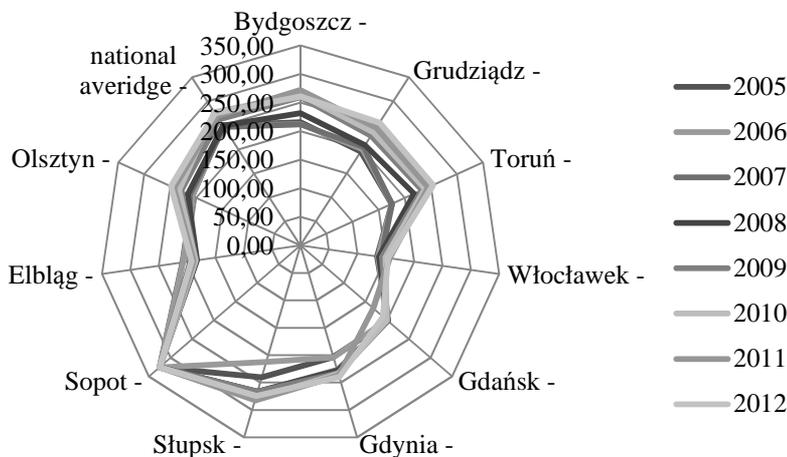

Source: as above.

Transport

Transport is a key sector for sustainable development due to the social and economic benefits that can be achieved while minimizing its adverse effects on society, the economy and the environment. Sustainable transport takes into account the criterion of access to transport services in accordance with the requirements of health and ecological safety (influence on ecosystems), taking into consideration the principle of inter-generation fairness, the criterion of cost-effectiveness and the criterion of control over the impacts on environment (negative external effects) and usage of space (land). In today's world, ensuring sustainable mobility and access to public goods and services is one of the key challenges to the achievement of the objectives of development. Sustainable transport system is the determining factor of the attractiveness of the site for its residents, but also for people visiting. (Grzega, 2012, pp. 7-158)

In the North macro-region, both the length of local public roads, as well as the length of cycle paths, increased annually. Again, the very positive results in this regard achieved Sopot.

Figure 9. Length of public roads with hard surface per 100 sq. km

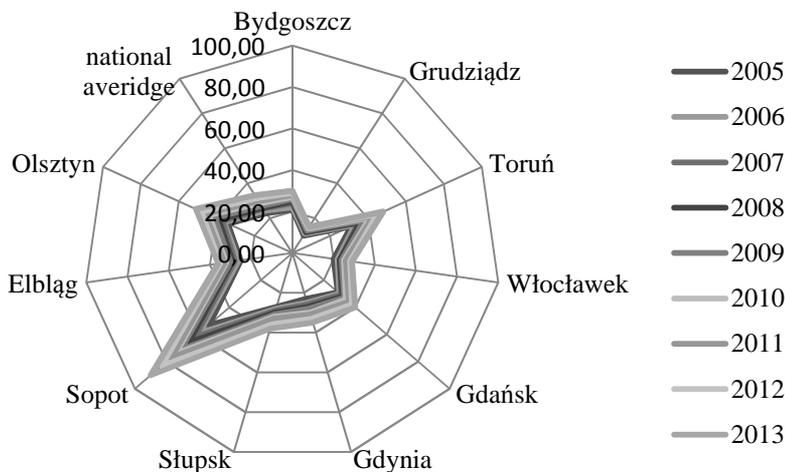

Source: as above.

The quality of governance / openness and participation

One of the primary goals in the pursuit of sustainable development is to achieve political and institutional order, known as good government—seen in terms of economy, politics or environment. Its manifestation is, among other things, the involvement of citizens in resolving social problems, prevention by the self-government from excessive exploitation of the environment, the effective financial management of local government units. (Wilkin (Ed.), 2013, pp. 11-; Ministerstwo Rozwoju Regionalnego, 2011, pp. 2-) Moreover, good governance is characterized by such features as openness, or access to public institutions and decision-making processes and participation, leading to an increase in social trust to institutions and public participation in political processes. The participation of local communities in solving social problems (socialization of the decision-making process) is the determinant of a civil society. (Glinski et al., 2010, pp. 23-)

In the macro-region, especially in Sopot, the number of registered foundations, social associations and organizations annually increased. Similarly, increased the turnout in local elections.

Figure 10. The number of registered foundations, social associations and organizations per 10 thousand inhabitants

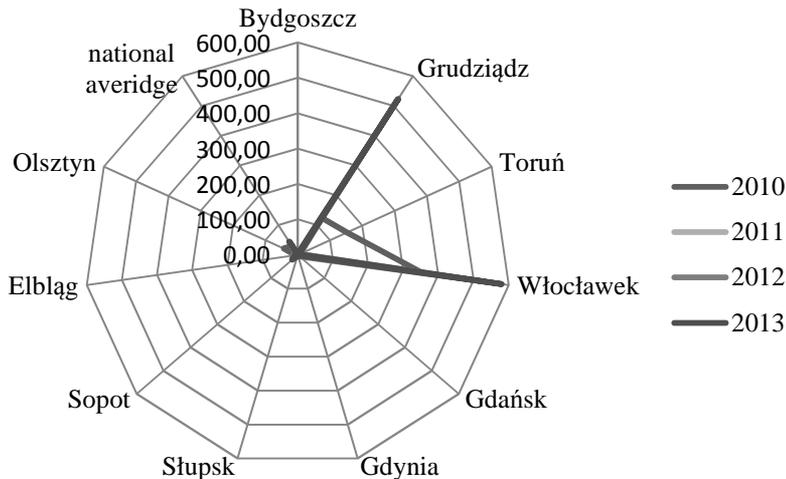

Source: as above.

Economic instruments

Among the tools used to support sustainable development there are such that aim at preventing excessive exploitation of the environment and exerting influence on local government to stabilise finances. Important in this respect is the rational management of the funds by government entities, as well as using environmental and operational charges. (Czternasty (Ed.), 2011, pp. 59-; Wojciechowski & Rabinowitch (Ed.), 2014, p. 47; Bryx (Ed.), 2014, pp. 5-)

Funds from the European Union for the funding of programmes and projects of the EU acquired by town districts of North macro-region were high, though not necessary increasing each year, contrary to what took place throughout the country. At the head were Grudziądz and Włocławek. At the same time, in most towns' budgets increased expenditure for debt, and decreased shares of investment expenditure in total expenditure budgets of towns.

Figure 11. Funds from the European Union for the funding of programmes and projects of the EU acquired by the cities per capita

Source: as above.

Conclusions

To sum up, over the past 10 years, in North macro-region, after the initial decrease in the values of the differential characteristics relating to intellectual capital, a significant improvement can be seen. At the same time, gross domestic product per capita in the macro-region annually increased its value.¹⁵ In addition, analyses prove positive forecasts for the values of the above characteristics.

Understanding, knowledge and creation of new social or economic values are innovations. (Gollin, 2008, pp. 115-128) They are caused by the fact that people are feel as a society a need to change the world for better. (Rogoziński & Panasiuk (Ed.), 2012, pp. 207-217) What is more, from the point of view of management theory, the collection of information by an individual (as well as financial, physical and human resources) belongs to the power supply, together with, first and foremost, planning, and organizing, conducting and controlling. (Błaszczuk, 2008, pp. 95-105) The management operations are carried out in the planning (development plans), plans implementation and monitoring their implementation. They concern processes and decisions, whose purpose is to define the measures, put them into practice and finally check their effectiveness. The evidence of the work carried out in these areas are regional development strategies in various regions.¹⁶ (Ekiert & Ziblatt, 2013, pp. 90-107)

They realize the clauses of the Treaty of Lisbon 17, in which a matter of the territorial dimension is of particular importance to the EU cohesion policy. As a consequence, the intervention is to a greater extent adjusted to the needs of different types of territories.

In addition, a characteristic feature of modern market economy, which determines all the activities and relationships within it, is competitiveness. One of the most important ways to increase this competitiveness is to create, and then consistently implement, a promotional strategy. (Białecki, 2006, pp. 70-) Nowadays, I attach particular importance to the process of innovation, which is crowdsourcing, which is drawing on the expertise and capacities of a given community. (Rupnik & Zielonka, 2013, pp. 3-25)

It seems that the best summary for this article, will be an encouragement to maintain and increase the momentum of described changes, as well as relying on coherent, harmonious and innovative development strategies, evaluating intellectual potential of their communities.

Banking Concentration in the Baltic and Western Balkan States – Selected Issues

JEL Classification: *G10; G20; G21*

Keywords: *banking market consolidation; banking market concentration; the Baltic States; the Western Balkan states*

Abstract: In a rapidly changing economic environment companies deepen their cooperation, which entails in all sectors of the economy. The progressive increase in market concentration, especially in the banking sector, has a purpose, which is to increase the benefits from the operation of various enterprises, e.g. credit institutions. The purpose of this article is to compare the tendencies within market structures in various countries which origin from similar political systems and which have got experience in transformation of banking sectors. The research concerns the Baltic and Western Balkan states. The study revealed a distinct change in the growth rate of market concentration and the number of banks.

The article is divided into two main parts. The first part consists of an analysis of the literature on the concentration of the banking market. It presents a discussion on the effects of changes in market structures, leading to an increase in its consolidation. The second part is devoted to empirical research in relation to changes in the degree of concentration of the banking sectors (using concentration ratios) and the number of banking institutions operating there. These sectors are divided into two groups: selected member states of the European Union (Lithuania, Latvia, Estonia) and the Western Balkan countries (Croatia – new member of the EU, Serbia, Bosnia and Herzegovina). In this section there are detailed descriptions of the banking markets' structures.

Introduction

In a rapidly changing economic environment companies deepen their cooperation, which entails changes in all sectors of the economy. The progressive increase in market concentration, especially in the banking sector, is driven by many factors, with an increase of the benefits resulting from operations of enterprises such as credit institutions as the most essential.

The purpose of this article is to present the changes taking place in the area of the banking sector consolidation, both in the EU member countries and these which are just applying for its membership. The research concerns economies from the East and Central Europe: the Baltic and Western Balkan countries. It is believed that similar changes in banking sector consolidation must have been recorded in the countries which had to transform their economies, including their financial systems. The study revealed a distinct change in the growth rate of market concentration and the number of banks in different groups of countries concerned.

The article is divided into two main parts. The first part contains the review of Polish and foreign literature on the issue of banking sector concentration. It presents a discussion on the effects of changes in market structures increasing their consolidation. The second part is devoted to empirical research in relation to changes in the degree of concentration of the banking sectors (using concentration ratios) and the number of banking institutions operating there. These sectors were divided into two groups: selected member countries of the European Union (Lithuania, Latvia, Estonia) and the Western Balkan countries (Croatia, Serbia, Bosnia and Herzegovina). This section also contains a detailed description of changes in the banking sector structures.

Methodology of the research. Content and Methods

The first part of the article reviews the literature on the subject of markets consolidation, including the banking sectors. It presents the discussion carried out among the scientists, concerning the changes taking place in the practice of banking. The second part considers the situation in banking sectors of the researched countries with reference to the transformation and redeveloping the sectors, as well as the current condition of the banking markets' consolidation. Further, a method of analysis is presented. The author compares the changes within the sector concentration and changes in the number the credit institutions. Basing on the above facts differing group

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

were selected. Despite the common history and experience of transformation, the researched countries cannot be considered as the homogenous group. The reasons for it are discussed further in this subchapter. The following research methods were used to gather and to analyze the qualitative and quantitative data: document review, literature review and international study. Various documents were collected: reports, financial statements covering the performance and structure of the studied economies. The theoretical part of the article consists of publicly available literature and legal acts review. The empirical part of the article is based on comparative analysis and studies of various reports for the period up to 2013. Data are provided by Eurostat, European Central Bank and the central banks of the selected countries.

Literature review – definitions

The issue of market consolidation has been discussed in the literature for a long time, providing various definitions. Poteraj (Poteraj, 2004, p.25) notes the difficulty in defining the concept of consolidation. He sees a discrepancy between Polish and English nomenclature, which makes it difficult to clarify the term. Discrepancies arise while trying to define the term more precisely. The most general and the least precise definition presents the term as the consolidation of union, fusion, the combination into a single whole, strengthening, consolidating. (Dunaj, 2001, p.406) Consolidation is not any combination, but is designed to strengthen economic performance of formerly separate entities.

Sector consolidation results from acquisitions which may have either friendly or hostile nature, as it was presented by Frackowiak. (Frackowiak, 2009, p.95) The author adds that the friendly acquisition is associated with a prepared program, common understanding of preliminary findings, and, above all, with exact explanation of reasons. Any decision in the case of such acquisitions must be commonly understood, discussed and communicated even to the smallest shareholders. Company operations, including suitability of employees is reviewed and adapted to the new conditions of its operation. In a friendly takeover, the evaluation of its effects will follow. In other types of purchase transactions, a company may be taken over with a use of one of two procedures. The more difficult one involves the gradual buyout of shares. The less risky procedure assumes submission of an offer directly to shareholders of a company. It can also be used to take over con-

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

trol, and to transform the company itself - mainly its board of directors. (Frąckowiak, 2009, p.102)

Among the authors there is a significant discrepancy as to the hierarchy of various types of transactions. Helin and Zord (1998, p.3) distinguish between two types of transactions which result in sector consolidation. These are mergers and acquisitions. The first one is defined as a combination of similarly sized entities, which establish a new corporation with evenly weighted shares. If this method is not applicable, the deal is recognized as an acquisition.

Sudarsan (1998, p.1-5) explains that merger and acquisition is a combination of two different organizational systems, with different cultures and values. Through this union of companies the expansion of an entity and, hence, its development is possible. The main objective is to connect companies to increase value of assets, sales and market share and to raise the value for shareholders. The merger is defined as the merging companies while sharing their combined resources, in order to achieve positive results of cooperation. As a result of the merger a new organization based on both united entities is created. The acquisition is a contract that gives one company an advantage and greater self-reliance. An acquired company becomes subordinated to a company making the acquisition. This view remains in accordance with definitions presented earlier by Bannock, Baxter, Davis (1992).

Poteraj, following Frąckowiak, divides purchase transactions into acquisitions and mergers. Acquisitions may take a form of share purchase, purchase of assets, powers of attorney, privatization, lease and joint ventures (Poteraj, 2004, p.30). Czekaj considers the consolidation as a form of fusion, in addition to mergers and acquisitions (Czekaj, Dresler, 2008, p. 244). According to his definition a fusion is a combination of companies, resulting in complete absorption of one company by the other, followed by the acquisition of assets and liabilities. Following the transfer, the acquiring company retains its name and legal entity, in contrast to the acquired company which ceases to exist as a separate legal entity (Poteraj, 2004, p.32). Consolidation is different from the merger because it forms a completely new legal entity. This means that participating companies lose their independence and cease to exist. An acquirer and an acquiree have a similar status and are in the same situation. Frackowiak uses another term to determine this case, which is the concept of incorporation. In his opinion, the acquisition can be considered as a loss of company control by one group of owners to another individual or to a group of people managing the compa-

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

ny. It distinguishes the acquisition from the merger and consolidation that does not result in total loss of the acquired institution dependency. Poteraj adds that the acquisition may be a phase of the process of a complete fusion of interests by means of a merger or a consolidation. (Poteraj, 2004, p.31) In this way, he shows them as two separate processes. However, the author also presents distribution, in which the merged and the holding companies are elements in the consolidation processes. (Poteraj, 2004, p.34). Lich-tarski recognizes the concept of holding as a concentration form. (Lich-tarski, 1999, p. 372) They are characterized by many restrictions of a company independence.

The above considerations show that there are many types of transactions resulting in an increase of a sector consolidation. Their features should be discussed, without taking into account their mutual dependence. It is considered to be reasonable to focus on the characteristics of different types of mergers, based on a few basic criteria. Each type of consolidation depending on legal form brings benefits for the involved companies. This may mean weaker market competition, takeover of the whole sector, smaller risk of growth of external company or opportunity to increase the market share while maintaining appropriate independence. For each acquisition method, however, there is an advantage which is highlighted at the beginning of this section. Consolidation in its assumptions is to improve the situation of the acquired business. Relations among enterprises may be of a more or less correct. Generally speaking, the process of market consolidation is related, on the one hand, to the need to achieve a high level of equity and the acquisition of skills (know-how), on the other hand – it is aimed to increase its market share in a short period of time.

Literature review – the case of banking sector

In the field of finance a prevailing view is that only large banking institutions have a chance to grow and compete in the global banking sector. (Kowalewski, 2003) This view is based on several assumptions. Only large institutions are able to finance the construction of a modern system of distribution of financial products and services, taking into account the current technological development. Banking institutions can benefit from the scale only by achieving a certain operating level. In addition, modern banking groups, due to demand or benefits of specialization and synergies, need to be able to offer a very wide range of financial services and products. At the same time, changes in the environment of the financial sector force banking

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

institutions to go out of local markets and build international presence. The increase in the scale of operations of banking groups increases demand for equity. Consequently, banks of the future will have a universal character, and will operate in international markets, offering all possible products and financial services to their customers using new distribution channels. (Freedman, Goodlet, 1998, p. 8-17)

Market concentration refers to the degree of dominance by large companies and their activities in the market. (Sathyam, 2002, pp. 7-20) The rise in the level of concentration may be caused by either growth of a parent company and / or by fall of the capacity of non-dominant firms in the market. The decrease in concentration can result from decrease in the size of a parent company and / or increase the size of non-dominant firms. (Athanasoglou et al., 2008, pp. 121-136) In the literature this problem is widely discussed. The effects of the research result in the emergence of various theories in relation to the banking sector. These theories can be grouped into these in opposition and the ones that support the sector concentration .

Opponents to the sector concentration show that there is a correlation between the degree of its concentration and credit supply. Berger (1995) on the basis of the US banking system, demonstrated that the liberalization of the geographical limitation of bank asset growth in the banking market can be considered as a partial cause of the credit crisis in 1989 - 1992. In addition, a higher level of the local banking sector concentration results in higher profits of the entire sector, which is achieved through higher prices of products and services. This is due to the fact that in a less competitive environment, banks can levy higher interest rates on their customers. The first study on the degree of concentration and competition in the banking sector was conducted in 1954 by Alhadef. With regard to the banking model based on SCP (Structure-Conduct-Performance) he argued that a higher degree of market concentration leads to higher prices. (Sharma, Ball, 2010, p. 95) If market concentration is positively correlated with market power of banks, the market concentration will increase the expected rates of return on assets (ROA). A relatively higher level of concentration is associated with lower level of socio-economic well-being and for this reason it is not desirable for the economy as a whole. Studies show that a monopolistic market power of banks, due to the increase of market concentration, increases the cost of capital and thus contributes to the increase in financing costs. And, in consequence, the lack of proper competition in the banking sector may negatively affect economic growth.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

Another argument against the increase in sector concentration is the fact that more concentrated banking sector exposes banks to financial problems. Advocates of this view point out that larger banks are more likely to receive state support as a result of policy described as "too big to fail", which is not applied to small institutions. (Boyd, Runkle, 1993, s.47-67) On the other hand, supporters of the concentration of the banking sector indicate that thanks to effects of scale achieved through consolidation transactions, the efficiency of bank performance is improved (Demirgüç-Kunt, Levine, 2000, pp. 1-32).

A part of the literature expresses the view that too much competition can destabilize financial markets and credit institutions although competition itself does not create instability. Systemic risk may appear independently from competition and in various market structures. Therefore, the relationship between stability and competition has been studied in the context of the consolidation of the financial sector by a Ferguson group. In the chapter of the Report on the consolidation of the financial sector, entitled "The impact of consolidation on financial risk", it is concluded that the only effective banks can survive in a competitive environment. It also indicates that the increase in competitive pressure may adversely affect the stability through the excessive increase of the risk by inefficient banks which are focused on maximizing their profits. There is a view that less concentrated banking sectors with a large number of relatively small banks are more vulnerable to financial crises in contrast to the highly concentrated markets where several large banking institutions operate. This is partly due to the fact that lower concentration is accompanied by stronger competitive struggle. Proponents of this opinion also add that larger banks can take advantage of diversifying their activities, which protect against potential financial perturbations (Allen, Gale, 2004, pp. 1-33).

Concentrated bank sectors achieve higher profits, with a higher level of resistance to the crisis. Relatively higher profits can create a specific financial buffer which can be used during potential problems in the market and which can contribute to the increase in the bank value, reducing the need to incur unnecessary risks in business. In addition, it is easier to monitor several large institutions than many small ones, therefore more effective market control is a characteristic feature of the strongly concentrated sector (Beck, Demirgüç-Kunt, Levine, 2003, pp. 26-27). Based on the empirical analysis of 47 banking crises in 70 countries Beck, Demirguz-Kunt and Levine showed that the concentration of the system is a stabilizing factor, and crisis probability is much lower in a concentrated banking system. In

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

addition, more institutionalized market is also better integrated and it is associated with a lower vulnerability to a crisis. It proves the stabilizing effect of theories concerning competition in the banking sector.

Gelos and Roldós (2002), analyzing the level of competition in economies in transition (1994-2000), said that despite the decline in the number of banks in the analyzed period, "the level of concentration did not increase, but did not decrease either." According to the authors, in the researched countries (including Poland), the negative effects on competition related to the consolidation, were offset by the increase of market-share of foreign capital. In this study, the authors point out, however, that the process of consolidation, especially in the Central Europe, was not completed then and therefore it was difficult to form definite conclusions. (Gelos, Roldós, 2003, pp. 1-28)

This review of the literature shows how important it is to study the level of concentration of the banking sector. The consolidation processes on the one hand can contribute to increased safety of the banking system by improving efficiency, but on the other hand - the effect of these operations may be opposite – it can increase the risk of doing business, and thus reduce safety. The final result depends on the concept of managing the process of mergers and acquisitions, and the condition of the business profiles of participants, along with individual decisions taken by operational managers. (Iwanicz- Drozdowska, 2002, pp. 29-36) As the degree of concentration of the banking sector and the competition affect its efficiency, it can be said that the degree of concentration can be recognized as a starting point for any analysis of the sector.

The banking industry in transition

The analyzed countries, namely the Baltic States and the Western Balkan States, have got a rather similar history of economy. Before declaring their independence all were parts of bigger federal countries: Lithuania, Latvia and Estonia were republics of the USSR and Serbia, Croatia and Bosnia and Herzegovina were Yugoslavia. They could not decide about the growth of their economies, as most state institutions were underdeveloped. It also refers to their banking sectors. The centrally planned economy, introduced at the end of the 20s by Stalin and functioning for the next six decades, as well as particular socialist market economy in Yugoslavia (so called the Third Way put into effect in the 1960s) had common features. The state banking sectors were based on large institutions, which assisted

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

by three or four special purpose entities, namely banks for agriculture, foreign trade and savings banks, with branches all over the country. The objectives of such financial institutions were limited to monitoring, facilitating and fulfilling credit plans. It meant that they could not run any independent policy and strategies since local politicians intervened in credit policies.

The first decisions during the process of transformation were: strengthening, widening and liberating financial sectors. The intention of such steps was to remove state from administration and distribution of capital, develop the banking sectors and allow them to accomplish their basic objectives. A common feature of the banking sectors in transition is that they are prone to crises. These crises are not caused by the liberalization of the legal environment, but its weakness and underdevelopment. The liberalization was demonstrated by a rather liberal policy towards formation of new banks. Another factor influencing the outbreak of the banking crisis was macroeconomic instability. It should be noted that the major reform - the privatization of the self-governed and the stated owned enterprises at the beginning of the 90s - was intended to contribute towards the development of capital markets as a source for raising new capital. Throughout the 90s a weak banking system was recognized as one of the reasons behind the decline of the a production sector, which, without a possibility of raising investment capital, could not restructure to face new market challenges. Although the causes of the crises differ between countries, two factors were common: the accumulation of bad, non-performing loans and inadequate system of regulation and supervision of the banking sector. This type of crisis was observed in Estonia in 1992, Lithuania and Latvia in 1995.

The same happened in the Balkan region. The crisis of the banking sector (by the state) first coincided with the civil war. Inefficiency of the banking sector was due to the civil war and the collapse of former Yugoslavia followed by vicious conflicts. During the war, the banking sectors and larger banks in particular, closely co-operated with governments in order to maintain functioning of the economy in relatively regular way. At the end of the war, the banks were reformed in various aspects : financially restructured, released from "bad debts" and capital-enhanced to be able to deal with forthcoming open market competition.

In Croatia, the first crisis, dating back to the early 90s, was the result of political, economic and legal instability as reminiscences of the vicious conflicts . It was caused by low responsibility level, meaning over-lending and low capital adequacy. In such a situation the government had to intro-

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

duce the recovery plans based on "*consolidation*" programs to restructure the banking systems. While some banks went bankrupt others were turned around e.g. Zagrebačka and PBZ. (Jankov, 1999).

What is common for the economies in transition is the fact that all suffered from some kind of crisis. The reasons for another crisis are explained by typical market economy problems and loopholes in legislation, characteristic of developed countries and manifested in lack of capital adequacy. Literature presents a number of reasons for outbreak of the crisis. The first factor is insolvency in the sector, measured by the percentage of non-performing loans. The recent problem is lack of financial discipline, to some extent resulting from unpaid state debts, and the costs incurred on restructuring the financial sectors. A key role in the outbreak of the crisis was played by a whole series of elements such as low quality of the management of banking institutions, ineffective interest rates, underdeveloped capital market, no privatization of the banking sector leading to ineffective control of banks, as well as high costs of their operation.

In 1998 Croatian banking sector was hit by the second wave of crisis. Sonje and Vujcic (1999) emphasized that the problem had appeared as early as 1989 when the value of loans exceeded the capital value of the sector. In 1991 almost half of the banks were insolvent (CNB, 1992). Because of deteriorating general economic conditions, the economy had to deal with problems of low-liquidity and generally not enough free capital to support restructuring and investment processes in the production sector. (Jankov, 2000) Three big banks, including Privredna banka, underwent government restructuring programs, in four basic steps. Non-performing loans were transferred from banks to government agencies. The second step was *recapitalization of the selected institutions*. Step three: the government took over the control and became their major shareholder, immediately announcing its intent to privatize the restructured banks, which was understood as selling them to foreign strategic investors. The last one was introducing new management in these institutions.

Fries and Taci point out that common features of the reforms in banking sectors in transition economies result from recommendations of the International Monetary Fund and World Bank along with so called Washington consensus that forced liberalization, restructuring and privatization of the banking sectors (Fries, Taci, 2002). Zoli (2001, p. 11-13) explained that government bailouts were performed to lift the burden of non-performing loans inherited from the socialist era, and worsened by the hyperinflation at the beginning of the 90s. She estimates that the fiscal costs of the banking

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

sector reforms in some transition countries, namely Bulgaria (1991-94), Czech Republic (1991-93) and Hungary (1992-93) accounted respectively for 58%, 67% and 40% of GDP. Because of the weaknesses of early 90. consolidation programs, Zoli estimates the total costs are actually higher. In case of Croatia, these costs are estimated for around 30% of GDP (Škreb, Šonje, 2001 and Jankov 2000).

The main element of recovery programs was to strengthen legislation and by-laws to improve quality of the banking sector supervision. Having introduced new banking law, the central banks issued a number of decisions regarding methodology of measuring capital adequacy and risk-weighted assets, classification of balance sheet items, off-balance sheet items and the bank risk exposures. Liberalization of laws enabling increase of foreign investors engagement in local banking sectors led to a very high share of foreign capital in these sectors. This situation allowed to consider the foreign strategic investors as a remedy for several problems. Foreign investors were to compensate budget deficit problems and provide a new flow of investment capital to support economic growth and technological know-how (and owners' control) to the finally efficiently restructured banking industry.

The concentration of the banking sector in Europe

A measure of market concentration includes not only the number of companies but primarily examines their relative size. In the literature a whole range of indicators can be found, which confirms that a comprehensive measure has not been established yet. The selection and their use depend on the needs and availability of data. This concerns mainly the concentration ratio (CR) and Hirschman-Herfindahl index, Grossack concentration dynamics, the Gini coefficient or the rate of entropy. As the further part of the study is based on the first two indicators, they will be explained in detail.

One of the basic indicators for the banking sector concentration is involvement of the largest credit institutions in the market (CRN), in relation to the size of assets or deposits. For this paper 5 major sector participants are considered – CR5. The main disadvantage of this indicator is that it excludes the participation of other institutions in the market, so that the indicator shows the degree of monopolizing the supply in the sector. O.Herfindahl and J.Hirschman Index (HHI) is a measure of the concentration expressed as an index for an aggregate of the squares of the share val-

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

ues of individual companies in the market. The index can range from 0 to 10,000 (100%²). The closer the market to monopoly, the higher the concentration ratio. In monopoly, the company owns 100% of the market, so the HHI index reaches 10,000. HHI decreases with growing diversity in market share and growing number of entities. [Rogowski, 2001, p. 43-44] The entities whose market share is much higher than the arithmetic mean for that sector have larger impact on the index value. The HHI index illustrates the strength of the market, however - to estimate the HHI value requires the data about all entities operating in the sector, which often are unavailable to the public. [Hirschman, 1964, p. 761]

The dynamics of the consolidation process in the years 1985–1999 is shown by a decrease in the number of banks by 40% in the US, and by 25% in the EU. At the end of the 80s takeovers of the largest British and American investment banks by commercial banks were considered crucial. It should be added that at the same time the process of consolidation of European banks was believed to remain at the development stage and was stimulated by establishing of the Monetary Union and the Common Market. European integration forced European financial institutions to fight for the dominant position in a new, expanded market. [White, 1998, pp. 3-13] Summary data for 2013 for Member States of the European Union show a big diversity in banking sector concentration. The CR5 index in the sector for the EU (15) ranged from the lowest level of approx. 33% in Germany and Luxemburg to 80% and more in Finland and the Netherlands, with the 2013 average 52%. The concentration measured with HHI confirms the above results. The average value of HHI for the EU (15) was 909 points, while in 2013 the highest score was noted in the Netherlands (over 3000 points) and the lowest in Germany (approx. 300 points). What shall to be stressed is the upward tendency of the sector's concentration in most member states, excluding only Denmark and Austria. The situation in the countries which joined the EU after 2004, seems rather different. Although in most new member states the concentration level of this sector is decreasing, there is lower diversity in concentration levels, comparing to the EU (15). In the analyzed period, the level of concentration of banking sectors in the countries of the "new EU" clearly decreased: 6% for the CR5 and 20% for HHI. Only in three countries - Slovakia, Bulgaria and Latvia, concentration ratios showed slightly increasing values.

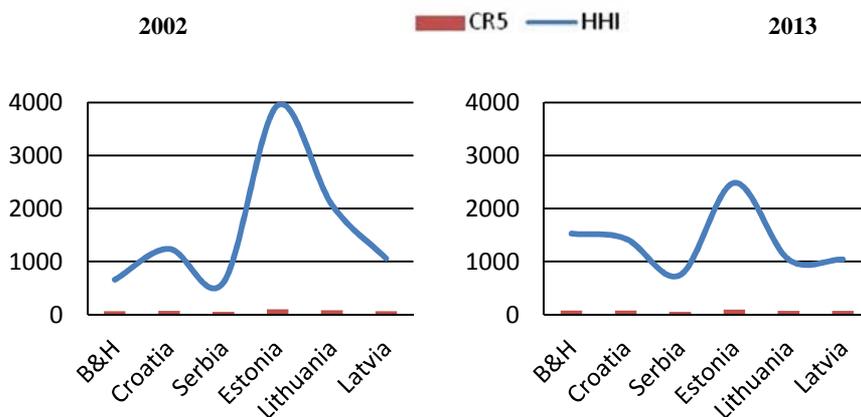

Comparing to other member states from the Baltic region, Lithuania and Estonia achieve the highest concentration level, measured with HHI and CR5 (see Figure 1). The highest share of the 5 largest credit institutions

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

was recorded in Estonia, where in the studied period the ratio reached 96% of its assets (in 2013 - 89.6%) and HHI - 3,434 pts. (in 2013 – 2,483 pts.). This proves the model of banking industries in these countries became closer to the oligopolistic competition, and concentration of the sector was much higher than in other EU member states. The sector concentration in Lithuania does not vary much for the one in Estonia. Latvian banking sector is much less concentrated, both in terms of HHI (1,038 pts.) and CR5 (64%) which remains much closer to the results of the averages in the EU (15) with rather stable situation in 2002-2013.

In Western Balkan region, a relatively high level of concentration of the banking sectors was observed. After the chaos of the 90s the situation began to stabilize in the transformation process. Due to a successful use of tools, such as: separation of commercial activities from central banks tasks, the central bank interest rates liberalization, restructurization and privatization of state-owned banks, and opening the sector to foreign capital. This contributed not only to substantial inflow of foreign capital, but also to high concentration in these markets. Only in Serbia the level of sector concentration measured by CR5 did not exceed 50% in 2013. In other countries, it ranged 70-80% of total assets. Moreover, it must be stressed that the concentration level in the region kept increasing, as presented in the figure 1.

Figure 1. Change of CR5 and HHI in the analyzed countries from 2002 to 2013*

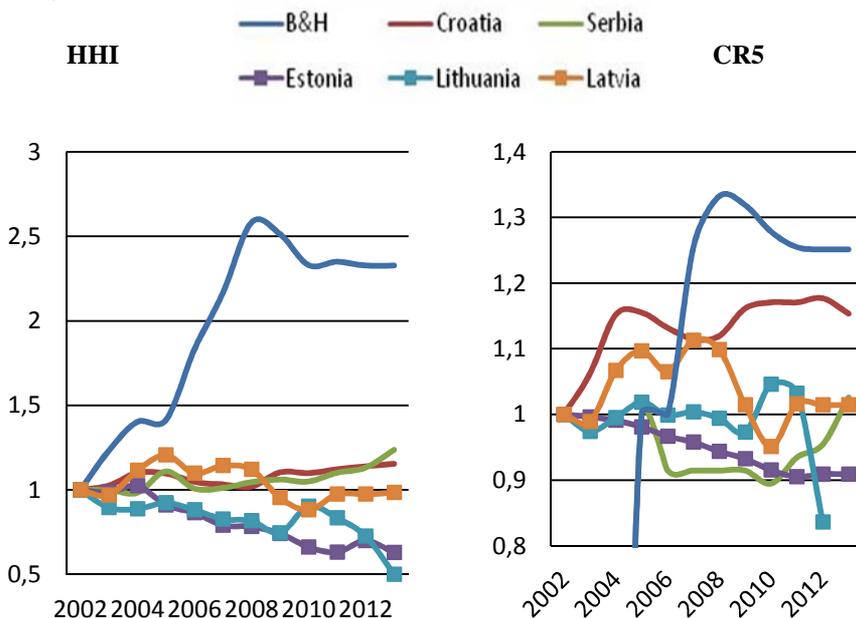

*The left axis presents HHI, the right – CR5

Source: author's elaboration, based on data from ECB and central banks of the non-EU countries

In the analyzed period, both groups of countries experienced diverse changes in concentration of their banking sectors. Sector concentration measured with HHI in the Baltic States decreased, but it rose in Western Balkans countries. In case of CR5 the general outlook is unclear and ambiguous. (Figure 2)

Figure 2. Changes of indices of CR5 and HHI in the analyzed countries (2002 = 100%)

Source: author's elaboration, based on data from ECB and central banks of the non-EU countries.

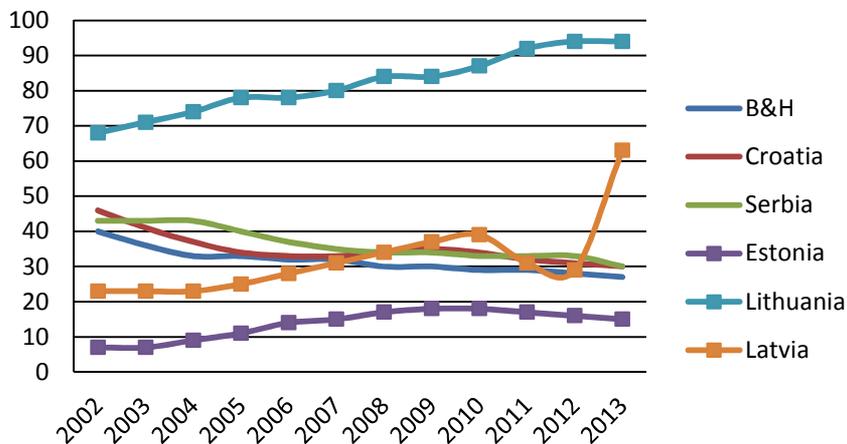

The Figure 2 depicts the differences in concentration processes in both analyzed groups. Firstly, the concentration level of the banking sectors in the Baltic States definitely decreased, both in terms of HHI and CR5. Latvia is the only example where the concentration level fluctuated and returned to the level achieved in 2002. In other countries in the region the concentration indices significantly decreased. Within the period of 11 years, the HHI dropped in Estonia by 38% and in Lithuania – almost by 50%. The decrease measured with CR5 is considerably lower: 9% in Estonia and by 20% in Lithuania.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

The characteristics of concentration in the Western Balkans were radically different. Due to ongoing transformation of the banking sectors in these countries, the indices were increasing. The strongest rise was recorded in Bosnia and Herzegovina, where HHI more than doubled, while CR5 rose by almost 33%. In Croatia both concentration indices rose by 24%, while in Serbia HHI rose by 15%, and CR5 remained at the same level.

Another characteristic feature of the banking sectors were considerable variations in the number of institutions operating in the sector - Figure 3. It must be emphasized that the evolution of the banking sector in the Baltic States led to structural change in the number of active market institutions. It should be noted that previously in EU (12) the number of banks increased in 6 out of 12 member states as a consequence of the consolidation of the sector. In the recent years, new technologies, introduction of different types of innovation and changes in distribution channels had a great impact on the sector. In the Baltic States (like in another 3 new member states: Malta, Slovakia and Poland) the number of credit institutions increased. In Lithuania the number rose by over 25, while in Latvia and Estonia – by 10 and fewer entities. In the Western Balkan region the number of banks operating there dropped, from over 40 to fewer than 30 entities.

Figure 3. Number of credit institutions from 2002 to 2013

Source: author's elaboration, based on data from ECB and central banks of the non-EU countries.

Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

The Fig.3 shows the data for Western Balkan countries on the left, the data for the Baltic States on the right side.

Next these countries were divided into groups, depending on the direction of changes in the level of concentration and the number of credit institutions. Table 1 shows the groups classified by the direction of the changes, for example, the A group includes countries where an increase in the concentration was accompanied by a decline in the number of institutions, and the I group, with countries where the concentration decreased in the absence of changes in the number of credit institutions.

Table 1. The groups classified by the direction of the changes

Concentration	Number of institutions	Group
↑	↓	A
↓	↓	B
↑	↑	C
↓	↑	D
↔	↔	E
↔	↑	F
↔	↓	G
↑	↔	H
↓	↔	I

Reference: author's elaboration.

Table 3 compares directions of changes in the number of participants in the banking sector and its level of concentration . It also presents dynamics of the above factors in 2013 compared to 2002. Table 2 shows the individual countries classified into appropriate groups, as shown in Figures 1-3.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

Table 2. Change of sector situation in 2013 in comparison to 2002

	CR5	HHI	Number of institutions	Concentration	Number of institutions	Group
B&H	2,33	1,26	0,68	↑	↓	A
Croatia	1,15	1,15	0,65	↑	↓	A
Serbia	1,24	1,03	0,70	↑	↓	A
Estonia	0,63	0,91	2,14	↓	↑	D
Lithuania	0,50	0,82	1,38	↓	↑	D
Latvia	0,98	1,01	2,74	↔	↑	F

Reference: author's elaboration, based on data from ECB and central banks of the non-EU countries.

In the group of countries that joined the EU in 2004 (Estonia, Lithuania and Latvia), dominated examples of a decline in the concentration with simultaneous increase in the number of institutions (D group). This meant new institutions weakened the sector concentration - as observed in Estonia and Lithuania. An increase in the number of institutions in the Baltic countries shows that there is still room for new institutions in the market. Within only one year in Estonia there were opened new banks: AS LHV Bank and Bank Snoras branch - the first foreign branch of the Lithuanian bank. New licenses were issued to the SEB Bank and Handelsbanken Bank branches in Lithuania.

In Latvia, the level of concentration remained unchanged despite an increase in the number of credit institutions (F group). The number of credit institutions changed only in 2013 as a consequence of the global financial crisis. The crucial fact is that such an increase did not impact negatively the level of concentration. It proves that new institutions were either small or their influence on the market was not significant. At the beginning of the transition period Latvia, comparing to other Baltic states, had the smallest foreign capital participation and liberal licensing policy. Licences were granted to Latvia Post Bank and the branch of Balti Pank Investeerigute group. It led to changes in the number of banks in the market. After a strong rise in 1993-1995, number of banks dropped by 20 only within two years as a result of consolidation processes, number of liquidation and bankruptcies. It should be noted that the largest banks in Latvia were established by consolidations. Latvijas Banka was recapitalized in 1995 by the Danish Unibank and adopting the name A / S Latvijas Unibanka. Later it became a member of consolidated SEB group in the Nordic market. In

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

1999 Rigas Komercbanka was taken over by Prima Bank, creating Pirma Latvijas Komercbanka PLC. In 2003 Prima Bank was taken over by the German NORD / LB Latvija, and later in 2006 - by DnB NORD Banka (Markiewicz, 2011, p. 153-154). The number of banks in Latvia began to increase again, mainly due to the entry of foreign banks, as this market attracted Scandinavian investors. SEB took over the majority stake in Latvijas Unibanka, and Swedbank in Hansabanka. Foreign investors to Latvian banks came from Germany, Estonia, Finland and Russia.

In the early years of transition in Lithuania, thanks to the liberal licensing policies, many new banks appeared. In 1992-1994, there were 28 banks, which was a very large number for such a small country, therefore the number of them fell by half, including two out of three biggest banks. An important problem for the Lithuanian banking sector was too little confidence of among clients that had to be slowly, gradually rebuilt. Lithuania was the last Baltic State, where foreign banks emerged, only after 1996. However, due to further expansion of foreign investors, their participation in the total banking assets grew significantly, reaching 90% of sector assets in 2006. The most important credit institutions in the Lithuanian banking sector are related strongly to Scandinavian capital, and were formed as a result of consolidation. Two biggest banks - Vilniaus Bankas and Hansabankas – were taken over in the process of privatization, respectively by Skandinaviska Enskilda Banken (SEB Bank) and Swedbank. In 2011 their share in sector assets amounted to over 47%. Another bank with over 16% of total assets –Bank Nord/LB Lietuva – belongs to a DNB Bank ASA - the largest financial services group in Norway.

In the first stages of the transformation in Estonia the number of banks fell while the banking sector faced an increase in regulatory requirements, new rules of prudence and growing competition in the banking sector. Smaller banks with insufficient capitals were liquidated or merged with other entities in order to increase their capital base. For many years only seven banks operated, out of which two largest: Hansapank and Eesti Ühispank were originally private banks, and belonged to Waldenberg family from Sweden. The number of banks in Estonia started to increase only after the European Union accession. Estonian banks also experienced several consolidations. Eesti Ühispank as the first bank which entered the banking sector after transformation merged with North Estonian Bank (1997), with Talinna Pank (1998) and then was taken over by the financial group SEB (2005). Another bank - Sampo Pank, which in 2008 was acquired by Deutsche Bank, had undergone various M&A transactions. First, in 1996

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

Estonia Forexbank incorporated Raepank, and after two years it merged with Estonian Investment Bank, creating a new group called Optiva Bank. Then it adopted a new name Sampo Pank. In 2007 a new bank Unicredit Tallin appeared, resulting from merging Estonian branches of Unicredit and HVB. In 1998 Hansapank merged with Eesti Hoiupank, later in 2005 privatized by Swedish investor Sparbanken Swedbank, which after 4 years became a sole owner. A few years later it was renamed for Swedbank AS - now it holds the biggest market share in the Estonian banking sector.

In Western Balkan countries, a deeper analysis shows their similarity to the countries of the "old" EU in reference to the direction of changes in the level of concentration and the number of banking institutions. Similarly to EU (15) countries, among the studied countries from the south a rise of concentration index prevails over a decline in the number of banks operating in the sector (A group). Such changes took place in all countries from this region. In Bosnia and Herzegovina, a decrease in the number of banks is due to the mergers of banks to meet capital requirements or license withdrawal by the central bank.

While the Baltic States banking sector is dominated by Nordic foreign investors, in the Western Balkan countries Greek and Italian banks are most active (Bastian, 2003, p. 81-107). Austrian and Italian banks were strongly engaged across the region (Breyer, 2004, p. 63-88). A high level of sector concentration coincided with high involvement of foreign inventors from neighboring countries. In Croatia, banking groups gradually developed during the 90s as a part of the process of sector consolidation and development. For the last decade the sector consolidation has been increasing through involvement of foreign capital in the national banking industry including the acquisitions of two biggest banks: PBZ (1999) and ZABA (2001) by two Italian bank groups: Grupo IntesaBCI and UniCredito Italiano. Before 1999 foreign banks access was allowed only in form of opening new branches. Acquisitions, both cross-border and domestic became dominant factors in forming sector structure after the second wave of turbulences. Since 2004, over 90% of the Croatian banking industry capital has been under control of eight foreign banking groups. Privredna banka and Zagrebačka banka are two biggest banks operating in Croatia. Together, counted by assets their sector share accounts for over 40%.

The Bosnian banking sector should be described not only by changing number of banks, but also by engagement of foreign investors. M&A transactions were main way of FDI in financial sector in this country. Looking at numerous foreign banks operating in B&H market, we can see that most

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

of them chose acquisitions to start their operations. Very important motive for acquisitions, instead of new ventures, was the fact that all acquired domestic banks had a strong wide network of branches and appropriate workforce which a new venture could never get in the short term. This trend, together with the legal requirement of minimum level of bank capital, forced small domestic banks to seek for foreign investors, which through mergers and acquisitions would allow to achieve the required level of capital and to survive in a highly competitive market.

While arguably still overbanked, by 2004 the number of banks in Serbia was cut to 43 - about one third of the 1995 peak (EBRD, 2005). Over the next few years, state ownership of the banking sector decreased and foreign banks increased their dominance. Through privatization, the share of state-owned banks declined to 15% of total assets in mid-2009. Privatization of banks resulted in foreign ownership of approx.75% of the banking sector, with subsidiaries of Austrian (27%), Greek (16%), and Italian banks (15,4%) keeping largest shares. Foreign ownership and presence in the banking sector became a crucial part of bank privatization in transition countries (Bonin, Hasan and Wachtel, 2005, p. 31-53). There was a particular need to reestablish public confidence in banks in Serbia. Serbia started late with fully fledged bank privatization. EBRD support encouraging foreign banks to enter and the presence of foreign banks provided such strong signals to the economy and investors that helped to restore confidence (Bastian, 2003). In 2006 the EBRD acquired a 25% stake in Komerciljalna Banka and National Bank of Greece bought Vojvidjanska Banka. Consequently, the market share of foreign banks rose. So far growth has been driven more by private consumption and FDI in Serbia than by domestic financial intermediation, but strong presence of foreign banks is likely to change this trend. In addition to the provision of financial services at market standards, foreign banks play a special role in meeting expectations by market participants, sending visible signals of change (Vives, 1996). For banks to fully reach their potential in bringing about healthy economic growth in Serbia, it was imperative to find a solution to the highly sensitive territorial issues, overcome the legacy of workers self management system and still pending enterprise restructuring.

Conclusions

Concentration of the banking sector, as measured by both HHI and CR5 indices changed during the quoted period, as a result of the consolidation of the sector. Also the number of institutions operating in this sector changed. In EU member states, trend of decreasing sector concentration is observed, accompanied by increases and decreases in numbers of credit institutions. The situation in banking sectors in the Western Balkans differed significantly, which could be explained by strong economic ties, particularly with Germany and Austria. It should be noted that the organizational integration of the Western Balkan banks with banking groups from Western Europe has not been accomplished to date. In terms of strategic decisions, acquisitions of local banks by foreign investors can be considered a harvesting strategy aimed at the benefits available in the sector which has not been fully developed yet. The relations between parent companies and their subsidiaries may evolve depending on the development of the general market conditions.

**Export Specialization in Services
of the Visegrad Countries**

JEL Classification: *F14; F15*

Keywords: *international trade; services; specialization; comparative advantage; Visegrad countries*

Abstract: The importance of services and the international trade in services is growing systematically. There are some reasons for that, especially the rapid development of IT technologies. This increase in the international trade in services is a global phenomenon, however there are some other specific issues, other than economic or technological, that might influence the trade in services in particular countries. As for the countries of the Central and Eastern Europe such a factor could be the accession to the European Union (EU).

The objective of the paper is to analyse the export specialization of the Visegrad countries in the international trade in services and how it changed over seven years after the EU accession. The service sector comprises of a variety of highly heterogeneous economic activities and the diversity of services is also reflected in the international trade of particular countries. Generally the trade theories deal with trade of goods, but there are some attempts already to apply these theories for services. To find out the export specialization based on the comparative advantage in particular services, the main categories of services are analysed based on the adjusted RCA index assumptions. Analysis prepared in the paper is based on the balance of payment statistics provided by the WTO.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

The article is concluded by discussing the questions about the export specialization of particular countries and how it changed after the accession to the EU.

Introduction

The importance of services in the economies is growing over the years. Services are also the growing component of the international trade worldwide. This same phenomenon applies to the economies of the Czech Republic, Hungary, Poland and Slovakia. These four Central European countries constitute the Visegrad Group - an alliance established in 1991 for the purposes of cooperation and furthering their European integration. In the last two decades those countries experienced significant changes in their political and economic development. The first change was a shift from the socialist planned economy to the market economy at the beginning of the nineties followed by signing the CEFTA agreement on the gradual creation of a free trade area between the Central European countries. And the second major change was the accession to the European Union in 2004. All those changes enabled the Visegrad countries to open to new markets and take advantages of the international trade not being bound to the previous agreements and boundaries of the Council for Mutual Economic Assistance (COMECOM). For all four states this freedom has resulted in increase of international trade, both in goods and services.

The basic objective of the paper is to analyse the export specialization of the Visegrad countries in the international trade in services using the Revealed Comparative Advantage (RCA) index and how it changed over time. The special emphasis is put on the period of accession to the European Union to find out if there was any influence of it on the Visegrad countries' international trade in services.

Methodology of the research.

Services are a very specific economic category. There are some discussion in the literature how to define services and how to measure the trade in services. In the paper there are two concepts of services tradability presented. Trade theories based on a concept of comparative advantage are widely used to analyse the trade in goods, however it is last two decades when economists have begun to examine how these theories might be applied to trade in services. In the second part of the study the theoretical framework for the revealed comparative advantage concept is presented, followed by a

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

discussion on usefulness or criticism on the application of this concept to the interpretation of patterns in the trade in services. The RCA index was constructed for the trade in goods purposes, but with setting two assumptions it might be used for analyzing the international trade in services as well.

The theoretical part of a study is followed by describing results. Firstly, the international trade in services if the Visegrad countries is analysed as for a volume and the share in the world's exports of services for years 1993-2011. Analysis is based on the balance of payment statistics provided by the WTO. The core part of the study starts with a calculation of RCA indices for each of the Visegrad countries corresponding to main types of services, such as: transportation, travel, communication services, construction, insurance services, financial services, computer and information, royalties and license fees, other business services, and finally personal, cultural and recreational services. The government services are not included. For the given RCA indices the trend analysis is made and time trend coefficient checked for significance at the 5% level. Then the tests of series are carried to examine whether the values of RCA for the Visegrad countries before the accession to the European Union were significantly statistically different from the values after the accession. The year 2004 is taken as a first year of the European Union membership. Test of series was used to verify if the RCA index values were random (null hypothesis) or if a country's accession to the EU has resulted in statistically significant changes in the RCA values (alternative hypothesis). The level of significance was set at 0.05. The paper is concluded with a summary of achieved results.

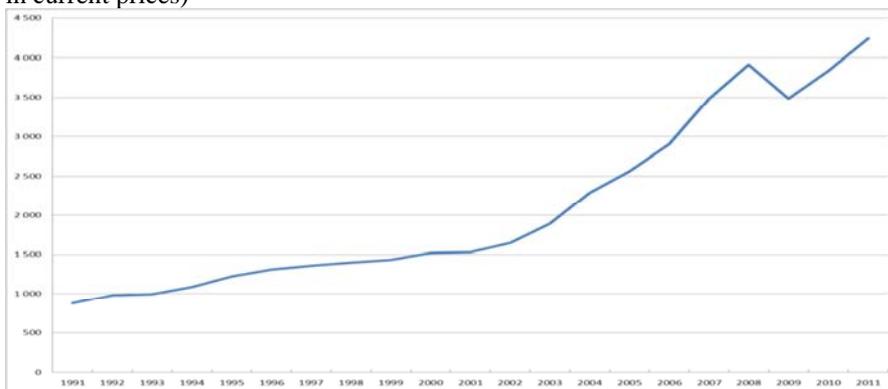

International Trade in Services.

Services in recent decades have come to play an increasingly important role in national economies (compare Francois & Hoekman, 2010, 642-692). Their share in GDP as well as in the creation of jobs is increasing. However, the growing importance of the services sector for the economies and economic growth does not correspond to the same extent on international trade in services. For many years, services have been considered as non-tradable due to specific features such as invisibility, non-storability, requirement of the physical contact between suppliers and consumers, close ties to movement of production factors (labour, capital), high level of specialisation and high trading costs (Grunfeld & Moxnes, 2003; Markusen, 2005). But recent years brought a significant change and services became

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

internationally traded to much higher extent. This phenomenon is noticeable especially since the beginning of XXI century (Fig.1). That resulted from two main factors: firstly due to the progress in communication technology and, secondly, due to the emergence of “new economy services”, such as e-commerce, software production and other services (IMF, 2003). With the development of technology the perception of services has changed. The possibilities provided by modern information and communication technologies have allowed for a relatively high degree of "independence" of services. In some cases, the usage of telecommunication or ICT networks has eliminated the proximity constrains. This allowed for breaking some ties between providers and consumers of services. Also an increase in the production of intermediate services and the growing importance of the outsourcing processes are largely responsible for the growth of international trade in services (Lennon, 2009).

Figure 6. Volume of world's export of services in years 1993-2011 (billion USD in current prices)

Source: own calculations based on WTO database (TsExports04564917).

Discussing international trade in services one has to be concerned with a problem of how to measure it. In the literature there are two definitions of international mobility of services: first one used by IMF or WTO and another one used by GATS. The first definition assumes that international trade occurs only when the two parties involved reside in two different states. These transactions are covered by balance of payments statistics and consist of the following categories of services: transportation, travel and other services: communication services, construction services, computer and information services, insurance, financial services, royalties and license

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

fees, other business services, personal, cultural and recreational services, government services.

Much wider definition was accepted in GATS, where four modes of supply were recognized:

- mode 1 - cross-border supply
- mode 2 - consumption abroad,
- mode 3 - commercial presence (foreign direct investments),
- mode 4 - presence of natural persons (compensation of employees and workers' remittances as approximate indicators of the mode).

This concept of mobility of services identifies all services as tradable (they can be provided and consumed under one mode or another) and covers all possible ways they can be delivered internationally (Kužnar, 2007).

The data collected by IMF or WTO based on the balance of payments that apply to the first definition do not correspond with the GATS's modes of supply. For this paper purpose we are using the nomenclature of trade in services used by the WTO, although we will not consider government services in this study.

Revealed Comparative Advantage – Theoretical Framework

The concept of comparative advantage was introduced by David Ricardo in 1817. Since then many economists have expanded the basic theoretical framework developed by Ricardo. They also tested the extent to which the theory of comparative advantage can be used to explain existing patterns of trade, however it is only in recent years that they have begun to examine how the existing theories could be applied to services (Feketekuty, 1988).

Comparative advantage means that every country can gain from trade if it concentrates its energies in the industries that make the best use of its resources and skills (Feketekuty, 1988). Therefore according to trade theories countries usually tend to specialize in exports of those services where they have a comparative advantage (Balassa, 1965; Deardoff 1985).

Generally trade theories deal with trade in goods, but considering the growing importance of services in the international trade, there are some discussions on trade theories for services going on (Deardoff, 1985; Stern & Hoekman, 1987; Snape, 1990; Stibora & De Vaal, 1995; Markusen, 2005). Although services in their characteristics differ significantly from goods, it might be assumed that to some extent the general ideas of trade theories for goods can be also applied to services and they can give some

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

useful insights about trade in services (Hindley & Smith, 1984; Stern & Hoekman, 1987; Feketekuty, 1988). The problem with trade in services is that it is largely invisible and it is tied to the international flow of persons, information, capital and good, and it is closely tied to foreign investments in the importing country. Therefore it is difficult to identify precisely what is being traded. But Feketekuty (1988) underlies that the unique characteristics of trade in services do not invalidate the application of existing international trade theory, but the existing theory will have to be expanded to deal with the unique aspects of trade in services.

There is also some criticism on the applicability of the concept of comparative advantage to international trade in services. Prieto (1989) argues that to extend to which markets become increasingly globalized, the concept of comparative advantage ceases to be relevant as in the theory it is valid only when there is no mobility of production factors. He also points out that more than endowment of physical resources (land and capital) there are few other key elements that determine comparative advantage in trade in services. These are: information resources, country's telecommunication infrastructure, orientation and volume of funds spent on investment and development, level and skill of labour, and the reliability projected by a given service supplier. The importance of other factors than physical endowment is also recognised by Daniels (1993) and Langhammer (2004). Daniels in case of trade in services sees the importance of finance capital, political and cultural factors, characteristics of human capital, the pattern and level of existing development in a country. While in the opinion of Langhammer (2004) comparative advantage for service trade cannot be compared to comparative advantage for goods trade because it follows other determinants such as existences of different modes of supply, domestic policy factors and specifics of factor movements.

Although all the discussion for and against it, the concept of comparative advantage has already a permanent place in the economic literature. But the question of how to measure it is still discussed. Attempts to quantify the comparative advantage has been taken by many economists: eg. Liesner (1958), Balassa (1965), Donges & Riedel (1977), Bowen (1983), Vollrath (1991), Dalum et al. (1998), Laursen (1998), or Proudman & Redding (2000).

Initial work on the determination of the strengths of the economy by analysing the structure of exports was carried by Liesner in 1958. Similar approach was adopted by Bela Balassa in 1965 by publishing a formula that allows the identification of areas of the economy, where a country has a

comparative advantage. Index Revealed Comparative Advantage is currently the most commonly used indicator to measure the competitive position in international trade (Mongiało, 2007; Lee, 2010). The traditional formula for this indicator was the subject of much criticism and attempts were made to modify it (Laursen, 1998; Yeats, 1985; Proudman & Redding, 2000). However, the primary version of the index remains popular and is widely used in the literature.

Originally the RCA index was concerned with trade in goods (OECD, 2003). This was a consequence of the development of the theory of international trade. But a stable growth in international trade in services as a result of globalization, technological changes, stronger international economic relations, especially between developed countries, was the impetus for the theoretical and empirical analysis explaining the issues of international trade in services (Wróbel, 2009). This index was created for international trade in goods, however with setting up two assumptions it might be used for analysing international trade in services (Deardoff, 1985; Mongiało, 2007). Those assumptions are as follow: 1. trade model reflects relative costs and differences in elements other than prices, 2. trade emerges between countries as a result of differences in endowments of economic resources, not as result of differences in technologies.

Revealed Comparative Advantage (RCA) index is defined as (Balassa, 1965):

$$RCA_{ij} = \frac{X_{ij} / \sum_i X_{ij}}{\sum_j X_{ij} / \sum_i \sum_j X_{ij}}$$

X_{ij} – exports of sector i from country j

$\sum_i X_{ij}$ – total exports from country j

$\sum_j X_{ij}$ – exports of sector i from the reference group

$\sum_i \sum_j X_{ij}$ – total exports from the reference group

The RCA index is a key indicator that measures the degree of export specialization in a particular product or industry. The equation defines export specialisation in terms of country j 's share in relevant group of countries exports of product i in relation to country j 's share of total services exports in reference group total services exports. In other words it expresses if the country possess a comparative advantage in the international ex-

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

ports of goods or groups of goods in relation to the share of the country's total exports in exports of countries taken as a benchmark. As a reference (benchmark) group, it can be taken a set of countries which provides a sufficient information on trade. Traditionally there are two sources of data used: OECD and World Trade Organization (WTO). Therefore choosing one of those two sources the reference group is defined. For this paper the WTO database was used.

The RCA can range from 0 to infinity. When RCA index equals 1 for a given sector in a given country, the percentage share of that sector is identical with the reference group average. When RCA is above 1 the country is said to be specialized in that sector exports, while the RCA is below 1 then there is no specialization. The closest to 0 the less important is that given sector in the country's export. And vice versa – the higher result the domination of particular sector in the country's exports is greater.

International Trade in Services of the Visegrad Countries

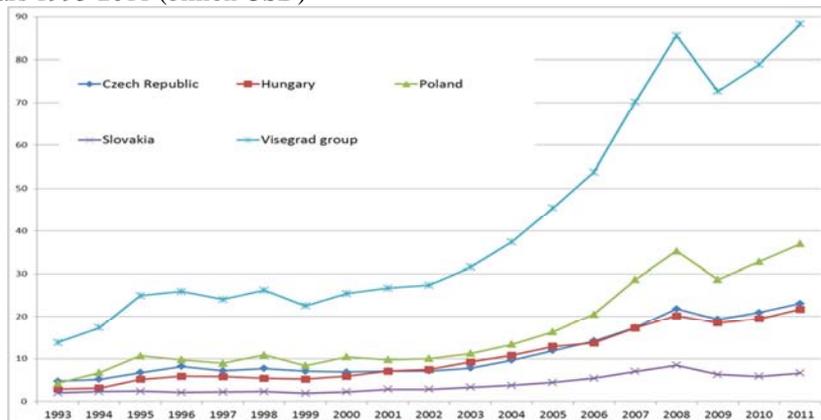

The world's international trade in services in 2011 accounted for 4 243,3 billion USD. The major players in terms of their export share were developed countries: The United States (13,96% of world's trade in services), the United Kingdom (6,75%) and Germany (6,08%). The total export of the Visegrad group amounted to 88,2 billion USD (2,08%). And individually Poland was placed on the 31 position among 185 countries that had reported to the World Trade Organisation (with 0,86% of share in the world trade in services), the Czech Republic placed 36 (0,53%), Hungary 37 (0,50%) and Slovak Republic 62 (0,15%).

Taking into account changes over time after the increase in the first half of nineties the share of the Visegrad countries in the world's trade in services decreased and stayed around the level of 1,6% for few years. The accession to the European Union had a positive impact on international trade in services for all four Visegrad countries what resulted in significant increase in volume of service trade for the Group (37 billion USD in 2004 up to 88 billion USD in 2011) and in increase in its share in the world's trade (1,63% in 2004 up to 2,19% in 2008 and 2,08% in 2011) (Fig. 2 and 3).

Specialisation in Exports of Services.

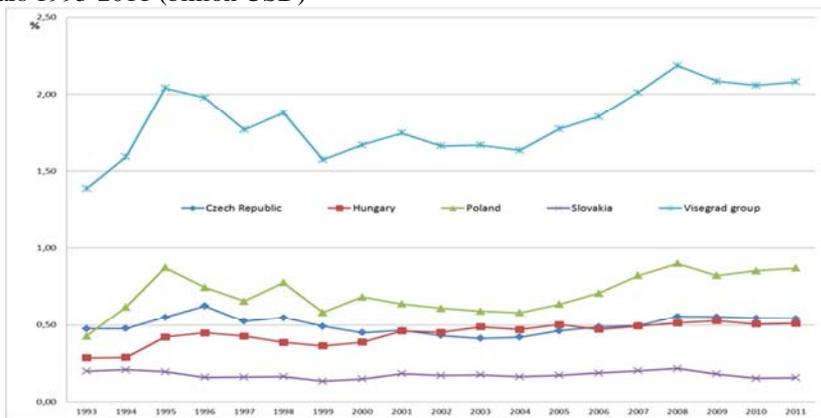

The service sector comprises of a variety of highly heterogeneous economic activities. This diversity of services is also reflected in the international trade of particular countries (Table 1).

Source: own calculations based on WTO database (TsExport04564917).

For the given RCA indices time trend analysis was made and time trend coefficient check for significance at the 5% level. There were also tests of series carried to examine whether the values of RCA for the Visegrad countries before the accession to the EU were significantly statistically different from the values after the accession in 2004 (the year 2004 was taken as a first year of the European Union membership). Test of series was used to verify if the RCA index values were random (null hypothesis) or if a country's accession to the EU has resulted in statistically significant changes in the RCA values (alternative hypothesis). The level of significance was set at 0.05.

Transportation services

Transport is usually one of the biggest sub-sectors of services in terms of its share in the national economy and in employment. It is also very heterogeneous itself, consisting of sea, air and other including land, internal waterway, space and pipeline transport services that are performed by residents of one economy for those of another, and that involve the carriage of passengers, the movement of goods (freight), rentals (charters) of carriers with crew, and related supporting and auxiliary services (WTO, 2013). The significance of that sub-sector depends on few factors whether the most important ones are geographical location and transport infrastructure.

The country with the highest RCA in transport services is Slovakia. In the pre-accession time the share of exports of transport services in the total Slovakia's exports was very high. The accession to the European Union in 2004 resulted in decrease of the RCA values to 1,5 level, however it is still the highest RCA in this sub-sector amongst the Visegrad countries. Also Poland specialises in exports of transport services – the RCA values are above 1 and there were no significant changes in the level of RCA during the analysed time, however after accession to the EU the situation in the exports of this sub-sector was stabilised. For the Czech Republic and Hungary there was an increase in specialization in transport services (both has statistically significant trends). Especially Hungary has noticed a very positive trend towards the specialisation in exports of transport services.

For all four countries the accession to the European Union had an impact on their exports specialisation in transport services, although it was different for different countries. The impact on the Czech Republic and Hungary was positive and the exports specialization in transport services was improving, in Poland the level of exports specialization stabilized, whether Slovakia was losing its dominance.

Travel services

Travel services are a broad category that includes goods and services acquired by personal travellers, for health, education or other purposes, and by business travellers. Unlike other services, travel is not a specific type of service, but an assortment of goods and services consumed by travellers. The most common goods and services covered are lodging, food and beverages, entertainment and transportation (within the economy visited), gifts and souvenirs (WTO, 2013).

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

At the beginning of the analysed time three out of four Visegrad countries specialised in exports of travel services: Hungary, Poland and the Czech Republic. Since 2004 all four countries had RCA above 1, although only for Slovakia the RCA values show a statistically significant upward trend and in 2011 Slovakia was specialized in exports of travel services in the highest extend. For other three countries time trend coefficient was negative. The largest decrease was noted for Hungarian exports specialisation, however accession to the EU had slowed down the decline. For the other Visegrad countries the accession to the European Union had no significant importance for their exports specialisation in travel services.

Communication services

Any of the four Visegrad countries had a permanent exports specialisation in communication services, which is a very broad category and encompass the transmission of sound, images or other information by telephone, telex, telegram, radio and television cable and broadcasting, satellite, electronic mail, facsimile services etc., including business network services, teleconferencing and support services. Also included are cellular telephone services, internet backbone services and on-line access services, including provision of access to the internet (WTO, 2013).

Before 2004 values of the RCA indices varied significantly for all countries. After the accession to the EU in 2004 there was firstly an increase in exports specialisation in the sub-sector for Slovakia, the Czech Republic and Hungary, but since 2006/2007 there was a downturn in RCA values. There is no export specialisation in communication services for Poland and calculations show that revealed comparative advantage in this sub-sector for Poland was characterised with statistically significant negative trend. The accession to the EU had no a significant impact on exports specialisation for any of the Visegrad countries.

Construction services

In the exports of construction services, which cover work performed on construction projects and installation by employees of an enterprise in locations outside the territory of the enterprise (WTO, 2013), the Visegrad countries are differentiated. The highest level of specialisation was recorded in Poland, however since 2003 there was a significant slowdown in the exports share (from 3,14 in 2003 to 1,63 in 2011). For the other countries

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

RCA indices did not indicate a specialisation in exports of construction services, although after 2009 the exports in this sub-sector revealed increase in comparative advantage for the Czech Republic and Slovakia. For all Visegrad countries the test of series shows that the accession to the EU had no significant statistical effect on their exports specialisation in construction services.

Insurance services

Insurance services are the very specific ones. They might be traded internationally, however traditionally customers prefer direct contact with insurers, especially when claims procedures are being proceeded. None of the Visegrad countries revealed exports specialisation in insurance services. Only for Poland prior to 2003 RCA indices in exports of insurance services achieved levels above or close to 1. After 2003 the share of these services in Poland's exports significantly dropped down.

Low RCA indices for exports of insurance services might be explained twofold. First that most of the insurance services might be internationally traded in the form of foreign direct investments. And secondly, since the end of nineties the ownership structure in insurance companies operating in the Visegrad countries was changing significantly towards the greater share of foreign capital (e.g. in Hungary insurance companies are nearly 100% foreign owned) what influenced the level of exports and imports of insurance services.

As the tests of series revealed Poland was the only of the Visegrad states that accession to the EU had an impact on exports specialisation in this sub-sector.

Financial services

In the financial services sub-sector the situation is nearly the same as for the insurance services, usually because financial services and insurance services are very closely related. Very often these same financial institution (e.g. banks) offer both financial and insurance products. Financial services as a sub-sectors cover financial intermediation and auxiliary services provided by banks, stock exchanges, factoring enterprises, credit card enterprises, and other enterprises (WTO, 2013).

Calculations of the RCA show that none of the Visegrad countries has revealed comparative advantage in exports of the financial services. More-

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

over time trends are negative and statistically significant. The worst situation during the analysed time appeared in the Czech Republic where the slope was negative in the highest extent out of all four Visegrad countries.

During the whole analysed period of time the situation in the exports of financial services sub-sector was decreasing steadily and there was no significant impact of the accession to the European Union. However due to the lack of data prior to year 2000 do not allow for more in-depth analysis if the association agreements with the EU and opening of the Visegrad countries financial services markets to the foreign direct investments of the financial institutions from the European Union Member States had no a direct influence on such low levels of comparative advantage in exports of financial services in the Visegrad states.

Computer and information services

Computer and information services are subdivided into computer services (hardware and software related services and data processing services), news agency services, and other information provision services (database services and web search portals) (WTO, 2013). This type of services gains importance since the nineties as the development of new technologies is progressing.

In this services sub-sector all Visegrad countries noted statistically significant positive trends. The Czech Republic, Slovakia and Hungary noted increasing comparative advantage over analysed time reaching RCA indices above 1. Poland was the only state that was characterised by RCA below 1, however the share of computer and information services in total Polish exports was permanently increasing. The increasing role of these services in exports seems to be a natural process while test of series has not revealed any significant impact of the EU's accession except for the Czech Republic.

Royalties and licence fees

The royalties and licence fees cover payments and receipts for the use of intangible non-financial assets and proprietary rights, such as patents, copyrights, trademarks, industrial processes, and franchises (WTO, 2013). These services arise usually as effects of research and development investments as well as investments in education and technology. These investments in countries of Central and Eastern Europe tends to be rather low and as a

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

result any of the Visegrad countries specialize in exports of royalties and fees. In overall their competitive position in this category of services was very low. The best position in this sub-sector was noted for Hungary, however only in 2005 the RCA for Hungary exceeded 1. The accession to the European Union had not a special impact on exports of those services in any of the Visegrad countries.

Other business services

Other business services consist mainly of business-to-business services and they are characterised by Markusen (2005) as knowledge-intensive requiring a high initial investments in human capital. This is a sub-sector that is intensive in skilled labour and whose final products are highly differentiated. These category includes trade-related services, operational leasing (rentals), and miscellaneous business, professional and technical services such as legal, accounting, management consulting, public relations services, advertising, market research and public opinion polling, research and development services, architectural, engineering, and other technical services, agricultural, mining and on-site processing (WTO, 2013).

During the analysed period only Slovakia was constantly losing its competitiveness in other business services. Other three countries were systematically increasing exports of those services achieving in 2011 the level of RCA above 1 for all of them.

The accession to the European Union had statistically significant positive effect on exports of Hungary and Poland. In case of Poland exports of other business services accelerated to reach 1,01 in 2009 from 0,53 in 2002, whether for Hungary since 2004 the comparative advantage measured by RCA was stabilised on the level above 1.

Personal, cultural, and recreational services

Personal, cultural, and recreational services are subdivided into two categories: audiovisual services and other cultural and recreational services. The first component includes services and fees related to the production of motion pictures, radio and television programmes, and musical recordings. The second category services includes services such as those associated with museums, libraries, archives, and other cultural, sporting, and recreational activities (WTO, 2013).

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

The country that highly specialises in personal, cultural and recreational services is Hungary. It noted the highest level of RCA index in 2005 (7,93), and since then its competitiveness was slightly decreasing, however it still stayed above 5. Also Slovakia specialised in exports of this category of services. On the other extreme is Poland where the competitive position was quite low until recent years. The Czech Republic was losing its competitiveness and since 2004 the comparative advantage index was achieving values below 1. The Czech Republic was also the only of the Visegrad countries for which the test of series revealed a significant negative impact of the accession to the European Union on the share of this category of services in the country's total export.

Conclusions

Services are growing in importance in international trade for all four Visegrad countries. There are 10 main categories of services covered by the WTO statistics: transportation, travel, communication services, construction services, computer and information services, insurance, financial services, royalties and license fees, other business services, as well as personal, cultural and recreational services. To find out the Visegrad countries degree of specialisation in international trade in different types of services the Revealed Comparative Advantage index was calculated. We found out that in years of 2000-2011:

- The Czech Republic specialised in transportation, travel, communication services as well as computer and information services. But during that time it lost its competitiveness in personal, cultural and recreational services.
- Hungary specialised in personal, cultural and recreational services. The level of competitiveness in this type of services was overwhelming all other types of services in Hungary's exports and it was the highest level amongst all Visegrad countries. Hungary specialised also in exports of travel and communication services, and with time it gained competitiveness in computer and information services as well as in other financial services.
- Poland had the greatest comparative advantage in construction services followed by transportation services and travel services. After 2009 there was an increase in specialisation in other business services.
- Slovakian comparative advantage was the greatest in transportation services and personal, cultural and recreational services. This country

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

specialised also in exports of travel services, communication services and construction services. At the end of analysed period computer and information services were gaining a greater share in Slovakian total exports of services.

- All Visegrad countries had a very low level of comparative advantage in exports of insurance and financial services as well as in royalties and licenses fees.

In 2004 the Czech Republic, Hungary, Poland and Slovakia became members of the European Union. Based on results of test of series we noticed that the accession to the EU had some positive effects on total exports of services for the whole Visegrad group. However this influence was different for particular countries and types of services. For all Visegrad countries the influence of the membership had an effect on exports of transportation services. Although for the Czech Republic and Hungary this impact was positive, for Slovakia negative and for Poland the accession to the EU had a stabilising effect on exports of transportation services. The positive impact of the EU membership was noted in exports of computer and information services in the Czech Republic and in exports of other business services for Hungary and Poland. Also the influence of membership on the exports of travel services for Hungary should be appraised as positive while it hampered the rapid decline in the comparative advantage that Hungary experienced in the pre-accession time. On the other hand, the negative effect of the accession was noted for exports of insurance services of Poland.

Conclusions based on the calculations of the RCA and test of series are that in years of 2000-2011 all Visegrad countries experienced changes in the level of their export specialisations in different types of services, but the very moment of the accession to the European Union had not a special impact on those changes, while they rather emerged from the natural economic development and changes in the national economies deriving from the harmonisation and adaptation to the requirements of the European Union membership that started after signing the association agreements at the beginning of nineties of twentieth century.

Monopolistic Markups in the Polish Food Sector

JEL Classification: *L11; L66*

Keywords: *markups fluctuations; Polish food sector; market power*

Abstract: Agri-food sectors are commonly considered as highly regulated, traditional and of strategic importance, mainly due to the food security issues. Changes in the related market structures are subject of constant interest because of their importance for competition and economic welfare of food producers and consumers. In Poland, a rising concentration among various branches of the food industry can be observed. The main objective of the article was to depict the changes of the market power execution in the Polish food sector and its branches in the period 2002-2013. As a measure of this phenomenon the markups of price above the marginal cost were applied and for their estimation two methods were used, namely the Roeger method involving primal and dual Solow residuals and the method based on the marginal cost of labor. Yearly data for 32 food sector branches and various accounting categories were used in the calculations. It was found that in the analyzed period the markup over marginal cost on average amounted to 10.4% and it was increasing over time. The labor input category seemed to be not sufficient for the markup calculation. The evolution of the monopolistic power in the Polish food sector appears to be associated not only with the business cycle, but also with the sector developments accelerated by the accession to the EU. Moreover, the differences in results for the branches indicate a considerable heterogeneity in the Polish food industry companies pricing practices.

Introduction

The market structures in the food sector are subjected to constant changes. As early as in 1966 in the report prepared by the US National Commission on Food Marketing it was admitted, that the concentration in many branches of the U.S. food sector reached too high, undesirable level, and the marketing and promotion expenses were excessive. It was also found, that through mergers and acquisitions companies are getting bigger exceeding sizes needed to maintain their operational efficiency (Sexton, 2000, pp. 1087-1104). The intensification of the concentration processes in the agro-food sector has a worldwide character and has been noticed in many countries for a long time. Figiel & Kufel (2013) proved high and statistically significant correlation between the value of the world agro-food production and the value of mergers and acquisitions in the world in the period 2000-2010.

Also in the Polish food industry concentration processes occur. In 2010 companies hiring more than 250 workers, constituting only 1.7% of all nearly 16 thousands companies operating in the sector, made 36.9% of all employment and 54.1% of all production value. Three capital groups generated 85.7% of revenues in the oil manufacturing, 78.5% in brewing manufacturing, 76.9% in tobacco industry, 75.6% in potato manufacturing and 69.6% in sugar manufacturing. In the period 2003-2010, while the production value increased from 102.7 to 158,9 billions of zł, the number of entities decreased from 19.52 to 15.97 thousands. The concentration ratio in sales in 2013 amounted to 0.79 in the food production, in the production of beverages – 0.66, and in tobacco industry – 0.37. It is also envisaged, that the process of concentration in the food sector will be continued and the role of large firms will grow (see Szczepaniak, 2012, pp. 78-87).

Potentially, a high concentration can contribute to non-competitive conduct of the main players in the industry, leading to higher markups of price above the marginal cost¹. There are plenty of research results concerning relation between concentration and market performance, e.g. (Tirole, 1988; Carlton & Perloff, 2005, pp. 263-267) and it turns out that most of the time the relation between these variables is positive and statistically significant, but weak. Therefore, increasing concentration in the Polish food sector data may be a sign of the increasing markups, what may influence competition and economic welfare of food producers and consumers. However, this

¹ This paradigm is known as Structure-Conduct-Performance (SCP) hypothesis.

may not be truth, as already in 70-ties it was proved, that the positive correlation between concentration and market performance is consistent with the increasing effectiveness hypothesis, as the company may create innovations, which decrease costs and improve quality. This makes it possible to increase markups and profits, as well as to gain dominant position in the market, what accelerates the concentration processes (compare Demsetz, 1973, pp. 1-9).

Consequently, the main aim of the article is to depict changes of monopolistic markups in the Polish food sector in the period 2002-2013. Moreover, two additional research questions were formulated. Firstly, can the markup be considered as a symptom of market power? Secondly, were labor markups changes good indicators of market power execution changes in the Polish food sector in the period 2003-2012? In order to answer the first question, the concept of markup and its estimation methods will be presented. Afterwards, the key aspects of methodology for markup estimation will be discussed, in particular the Roeger (1995) and the Rotemberg & Woodford (1999) methods. Then, the results of applications of both methods will be showed and compared in order to assess the appropriateness of the second method for the Polish food sector.

It needs to be added, that there have been no enough extensive attempts to measure market power in the Polish food sector and the main point has been rather to discover the price transmission mechanism or the power distribution among the food marketing chain actors (compare Seremak-Bulge, 2012, pp. 5-24; Urban, 2001, pp. 1-120). The only studies were carried out by Gradzewicz & Hegemajer (2007a,b). The average markup in the Polish food sector in the period 1996-2004 estimated with the Roeger method markups amounted to 0.224, what was the third highest result among all manufacturing industry branches.

The concept of markups and methods of their estimation

The markup is a gap between the price (P) that a firm charges and its marginal cost (MC): $\mu = P/MC$ (see Samuelson & Marks, 2009, pp. 118-120; Pindyck and Rubinfeld, 2013, pp. 372-373). The total revenue (TR) of the company can be written as follows: $TR = Y \cdot P$, where Y is an output, and the change in total revenue caused by production of an additional unit is: $MR = \frac{dTR}{dY} = P + Y \cdot \frac{dP}{dY}$. From the other side, a price elasticity of de-

mand can be expressed as follows: $\varepsilon = -\frac{dY}{dP} \frac{P}{Y}$. Hence we have:

$\frac{P}{\varepsilon} = Y \cdot \frac{dP}{dY}$ and $MR = P + \frac{P}{\varepsilon} = P\left(1 + \frac{1}{\varepsilon}\right)$. The optimal markup is a markup received under the profit maximizing condition: $MR = MC$. From the formula for markup we get: $MC = \frac{P}{\mu}$. Consequently we have: $P\left(1 + \frac{1}{\varepsilon}\right) = \frac{P}{\mu}$, and the optimal markup can be expressed as follows: $\mu = \frac{1}{1 + \frac{1}{\varepsilon}}$. Two main

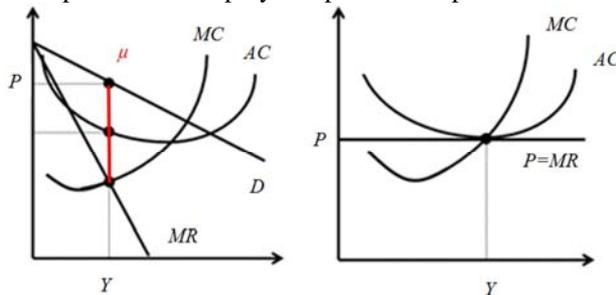

conclusions are, that the increase of price elasticity of demand (absolute value) causes the markup to fall and vice versa, and that the optimal markup calculation allows the enterprise to set the profit maximizing price:

$$P = \frac{MC}{1 + \frac{1}{\varepsilon}}$$

Olive (2002) enumerated five economic meanings of markups. Firstly, they indicate a market power. Also according to Church (2000), a market power is a firm ability to profitably rise the price above the marginal cost². Although markups are rather a realization of this ability, not this ability itself, because the markup grows along with the perturbation between a price and a marginal cost, it's commonly used as a measure of market power and this two concepts are used interchangeable. Because a firm has a market power, when it concerns rising price above marginal cost as profitable, the market power depends on the market structure. The situations of perfect competition and monopoly are presented in figure 1. We can see that while in the first situation market power of the monopoly amounts to μ , in the perfect competition a firm has no ability to exercise market power and because price equals marginal cost, the markup amounts to zero.

² This is the most common definition of market power. However, also other can be met, e.g. in the opinion of Pindyck and Rubinfeld (2013) a market power is either a seller or a buyer ability to influence a price of a product.

Figure 1. Market power in monopoly and perfect competition*

*AC – average costs

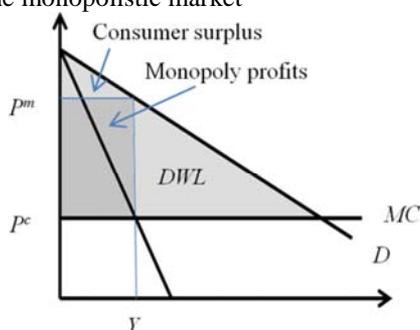

Source: own elaboration based on Marks & Samuelson (2009, pp. 436-440, 468-479).

The reason for the dependence of the markup on the market structure is its relationship with price elasticity of demand, so on the character of the demand curve. In the case of homogenous goods, the higher number of competitors, and in the case of diversified products – the higher cross-price elasticities of demand, the higher is the price elasticity of demand and the lower is the market power exercised by the company on the imperfectly competitive market (see Church & Ware, 2000, pp. 31-34). Tremblay & Tremblay (2012, pp. 328) concluded, that the market power measured by markups is growing when: there are entry barriers, what implies higher concentration on the market; there are no potential entries; products are diversified; firms compete more by quantity than by price; firms create effective cartel; firms make strategic investments in order to decrease costs or to rise prices in the future. Because these factors intensities are different depending on the market, also the markups illustrating market power are different depending on the market. What should be added however is, that while calculating market power a proper attention should be paid to the time and market boundaries. Moreover, the business cycle and technological change can matter (Church & Ware, 2000, pp. 147).

The second meaning of markups is that they represent the welfare loss for the society (see Olive, 2002, pp. 3). The common welfare measure is the total surplus, being the sum of consumer and producer surpluses. It's a value, which producers and consumers are willing to pay for the equilibrium quantity at the equilibrium price. This welfare measure is maximized in the competitive equilibrium and each departure decreases its value. The competitive equilibrium is characterised by the desired efficiency and welfare levels and according to the Pareto rule, no actor can improve its position without worsening the situation of the other one (see Carlton & Pres-

toff, 2005, pp. 69-71). In order to measure this effect of markup pricing, the so called deadweight loss (DWL) is calculated. It's a cost of inefficient market performance incurred by the society, measured by the loss in total surplus comparing to the situation of competitive equilibrium. Church & Ware (2000) highlighted, that this allocative inefficiency leading to lowering the volume of production is the main outcome of market power execution. DWL in the situation of a monopoly is presented on the figure 2. We can observe that the output in the monopoly is lower than the optimal one ($Q^m < Q^c$). The loss of welfare in the uncompetitive market structures may be an effect of: monopolistic pricing practices, achieving excessive profits, reduced production, unused production capacity, weak tendency to cost reduction and to innovate because of the lack of competitive pressure.

Figure 2. DWL on the monopolistic market

Source: own elaboration based on Church & Ware (2000, pp. 33-36).

Thirdly, according to Olive (2002) markups are incentives for investment and technological change. Yet Schumpeter (1965) noticed that market power encourages to research and development. Without the perspective of monopolistic profits companies wouldn't have enough incentives to conduct research and development. What is interesting, DWL will have positive meaning, when it enables innovation regarding products and technologies leading to growth of the economic as well as life quality standards.

Fourthly, markups at the aggregated level change along the business cycle and are used as an argument in the macroeconomists discussions on the character of cyclicity of real wages (see Olive, 2002, pp. 3). Finally, markups are used as key exogenous variables in the macroeconomics models of inflation and general equilibrium models (see Olive, 2002, pp. 3), especially in the New Keynesian dynamic stochastic general equilibrium (DSGE) models, utilized nowadays in the majority of central banks for the

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

needs of monetary policy, in which the markups level is an exogenous variable and the assumptions about their cyclicalities are used for the construction of the supply side.

The point is that high markups and their variability influence the price dynamics in the business cycle, what influences the monetary policy effectiveness. Monopolistic structures in the economy, reflected by high markups, change economy response to both demand and supply disturbances. Anticyclical markups and its positive influence on inflation imply asymmetric reaction of monetary policy and economic activity variation. During economic downturns the fact, that inflation doesn't fall as much as when markups were stable, limits the abilities of central banks to sustain the aggregated activity level through the decrease of interest rates. On the contrary, the markups decrease in the expansion phase limits the inflation pressure and enables central banks to delay introduction of an restrictive monetary policy.

What is interesting, the Keynesian models depend on countercyclical markups only since early 80-ties. Before, the leading was assumption about sticky wages (compare Taylor, 1980, pp. 1-23), but because the earlier models appeared to contradict the cyclical properties of real wages, researchers changed the assumption of sticky wages for the one of sticky prices (see Gordon, 1981, 493-530; Rotemberg, 1982, pp. 517-531). As stated Nekarda & Ramey (2013), from the Woodford model (2003), in all New Keynesian models markups fall in response to positive demand shifts. Sticky prices together with procyclical marginal cost cause, that an expansionary monetary or government spending shock decreases the average markup. This is also true in the newest models built in the New Keynesian spirit joining sticky prices and sticky wages, e.g. (Erceg et al., 2000, pp. 281-313; Smets & Wouters, 2003, pp. 1123-1175; Christiano et al., 2005, pp. 1-45). In the inspiring model of Jaimovich and Floetotto (2008), procyclical entry of firms leads to countercyclical markups, and then to procyclical TFP. Regarding inflation, Ball et al. (2003) or Steinsson (2005) in their New Keynesian models assume positive correlation between markups and inflation, and a markup change is that of the a cost nature. It's also worth highlighting, that understanding the mutual relation between markups and prices is especially important in countries, which set inflation targets, e.g. in Poland.

The above discussion show that markups are and can be regarded as symptoms of market power. Moreover, it can even be stated, that they are the only right indicator of the market power execution, and it's hardly im-

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

possible to think about the better one. In practice, in order to assess the market power execution, the so called Lerner index is utilized: $\mathcal{L} = \frac{P-MC}{P}$. Its values for different structures in the static setting are presented in table 1. For diversified products and dynamic markets characterized by today's production and sales influencing future profits, e.g. those including learning-by-doing, the Lerner indexes formulations are far more complicated, see (Tremblay & Tremblay 2012, pp. 336-337).

Table 1. Lerner index in different market structures*

Market structure	\mathcal{L}
Perfect competition	0
Bertrand oligopoly	0
Cournot oligopoly	$1/(n \cdot \varepsilon)$
Cartel	$1/\varepsilon$
Monopoly	$1/\varepsilon$

* ε – the absolute value of the price elasticity of demand, n – the number of firms with perfectly homogenous

Source: Tremblay & Tremblay (2012, pp. 314).

Because the Lerner index calculation is usually problematic, mostly because of the lack of data on marginal costs (available data typically include only average cost), other market power measures have been developed. Majority of them is focused on profitability, e.g. q Tobin, rate of return, profit to sales ratio, relative profit diversification (see Tremblay & Tremblay, 2012, pp. 311-318), and they are not free from drawbacks. Firstly, price can exceed marginal cost even when profits are zero, e.g. in the monopolistic competition. Secondly, most of companies it's hard to identify share of revenue, costs and assets connected with the certain products or markets. Thirdly, they employ accounting profits being only a weak approximation of economic ones (compare Carlton & Perloff, 2005, pp. 249-252).

Consequently several methods of indirect markups estimation were developed, e.g. total cost function estimation, the price response to a change in costs, New Empirical Industrial Organization (NEIO), stochastic frontier method, game theory, overall efficiency loss estimation, single input margin (see Tremblay & Tremblay, 2012, pp. 318-326; Einac & Levin, 2010, pp. 145-162; Rotemberg & Woodford, pp. 1051-1135). The main disadvantage of them is, hard to state, which part of the difference between revenues from sales and marginal costs is a result of market power (a relationship between price and marginal costs), and which is a result of economies

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

of scale (a relationship between average and marginal costs) (compare Gradzewicz & Hagemeyer, 2007a, pp. 515-540). Then, it is assumed that there are no economies of scale.

Methodology of the research

In order to assess market power execution in the Polish food sector two methods were chosen because they are the most well-known and the most frequently applied regarding problems on micro and macro levels (compare Gradzewicz & Hagemeyer, 2007b, pp. 13-27; Nekarda & Ramey, 2013, pp. 1-47). The first one was developed by Roeger (1995), and the second one by Rotemberg and Woodford (1999).

The Roeger method is one of the methods studying the price response to a change in costs. The main idea of this group of methods is that on the perfectly competitive market each increase in costs will be completely transmitted on consumers, whereas on the imperfect one the pass-through is different from zero. Therefore, the range, in which price responds to change in costs, can be used for markup estimation. In most studies taking advantage of this broad category of methods, directly or indirectly Hall (1988) developments are used. He calculated markups from the following equation: $\Delta \ln \frac{Y}{K} = \mu \Delta \ln \frac{X}{K} \cdot \theta + \xi$, where Y is output, K is a capital input, X is a labor input, and θ is a share of labor costs in production value. The main problem with this method was that, disturbances in unobserved productivity are a part of random error of the model and therefore could be correlated with the production factors, what induces a markups estimates bias. This problem was solved by introducing instrumental variables influencing unobserved residual in the Solow model, which influence changes in employment and demand, and not in productivity, e.g. world oil price, government military expenditures, dummy variable connected with ruling party. Additionally, because data must be in real terms, there is a problem concerning the influence of products quality changes on prices. Finally, markups estimates were too high comparing with no profits in certain branches.

The great deal of these problems was solved by Roeger (1995). Whereas Hall took advantages of the primal Solow residual (SR) based on the production function, Roeger added the dual Solow residual (DSR) based on the cost function. By SR we understand a share of a technology change in the production, and by DSR a share of a technology change in the change of total costs of production. Using primal and dual Solow residuals enables

elimination of unobserved productivity variable from the regression equation (no bias under constant returns to scale), what gives more precise and closer to reality markup estimates (see Gradzewicz & Hagemeyer, 2007b, pp. 13-27). Consequently, the estimation could be performed with normal least square method. There is no need to look for instrumental variables.

Moreover, because of the assumption, that markups are constant in particular branch in particular year, data may be in nominal terms (see Gradzewicz & Hagemeyer, 2007b, pp. 13-27). Additionally, because of the assumption of constant returns to scale, if returns to scale are constant, the estimators are equally burdened in time (compare Gradzewicz & Hagemeyer, 2007b, pp. 13-27), what doesn't influence the markups dynamics. Consequently, this method is relevant to study markups dynamics, as well as the impact of exogenous variables on markups. Roeger estimates represent lower bound of markups in branches with growing returns to scale, large sunk costs and strong rigidity of adjustments over the business cycle (compare Martins et al. 1996, pp. 1-47). The assumption of constant returns to scale was however broadly criticized.

If we assume, that the production function is: $Y(X_1, \dots, X_N, K, E) = F(X_1, \dots, X_N, K)E$, where Y is an output, K is a capital input, X_i are inputs of production factors from 1 to N , and E is a neutral Hicks technology change, after logarithmic differentiation we get: $\frac{dY}{Y} = \sum_i \frac{\partial Y}{\partial X_i} \frac{dX_i}{Y} + \frac{\partial Y}{\partial K} \frac{dK}{Y} + \frac{dE}{E}$ (see Gradzewicz & Hagemeyer 2007b, pp. 13-27). Assuming perfectly competitive production factor markets, we have: $w_i = \frac{\partial Y}{\partial X_i} \frac{P}{\mu}$, and $w_k = \frac{\partial Y}{\partial K} \frac{P}{\mu}$, where w_k and w_i are prices of capital and other production factors accordingly, P is a price of a final product, μ is a markup. Assuming homogeneity of production function, we have: $TC = MC \cdot Y$. The shares of production factors costs in the total costs can be expressed as: $\alpha_k = \frac{w_k K}{Y \cdot MC}$ and $\alpha_i = \frac{w_i X_i}{Y \cdot MC}$. We get then: $\frac{dY}{Y} = \sum_i \frac{w_i X_i}{Y \cdot MC} \frac{dX_i}{X_i} + \frac{w_k K}{Y \cdot MC} \frac{dK}{K} + \frac{dE}{E}$. Because the shares of production factor costs in total revenue are as follows: $\theta_i = \frac{w_i X_i}{PY}$, we obtain: $\alpha_i = \frac{w_i X_i}{Y \cdot MC} = \theta_i \mu$, and $\alpha_k = \theta_k \mu$, accordingly. Assuming constant returns to scale, from the Euler theorem, we have: $\sum_i \alpha_i + \alpha_k = 1$. Then: $\frac{dY}{Y} = \sum_i \theta_i \mu \frac{dX_i}{X_i} + \theta_k \mu \frac{dK}{K} + \frac{dE}{E}$. After transformations we can get the

primal Solow residual: $SR = \frac{dY}{Y} - \sum_i \theta_i \frac{dX_i}{X_i} - (1 - \sum_i \theta_i) \frac{dK}{K} =$
 $(1 - \frac{1}{\mu}) \left(\frac{dY}{Y} - \frac{dK}{K} \right) + \frac{1}{\mu} \frac{dE}{E}.$

From the cost function we can obtain marginal cost: $MC = \frac{G(w_i, \dots, w_N, w_K)}{E}$. After logarithmic differentiation we get: $\frac{dMC}{MC} = \sum_i \frac{\partial G}{\partial w_i} \frac{dw_i}{G} + \frac{\partial G}{\partial w_k} \frac{dw_k}{G} - \frac{dE}{E}$. In accordance with Shepard lemma we notice that: $X_i = \frac{\partial C}{\partial w_i} = \frac{\partial G}{\partial w_i} \frac{Y}{E}$. Hence, we have: $\frac{dMC}{MC} = \sum_i \frac{X_i dw_i}{Y \cdot MC} + \frac{K dw_k}{Y \cdot MC} - \frac{dE}{E}$. Assuming constant markups in certain year in a certain branch $\frac{dMC}{MC} = \frac{dP}{P}$, we have: $\frac{dP}{P} = \sum_i \frac{\theta_i \mu dw_i}{w_i} + \frac{(1 - \sum_i \theta_i \mu) dw_k}{w_k} - \frac{dE}{E}$. After transformations we can get the

dual Solow residual: $DSR = \sum_i \theta_i \frac{dw_i}{w_i} + (1 - \sum_i \theta_i) \frac{dw_k}{w_k} - \frac{dP}{P} =$
 $(1 - \frac{1}{\mu}) \left(\frac{dw_k}{w_k} - \frac{dP}{P} \right) + \frac{1}{\mu} \frac{dE}{E}.$ Then, subtracting DSR from SR , would give us the Nominal Solow Residual (NSR), with the technological change cancelled out: $NSR = \frac{dY}{Y} + \frac{dP}{P} - \sum_i \theta_i \left(\frac{dX_i}{X_i} + \frac{dw_i}{w_i} \right) - (1 - \sum_i \theta_i) \left(\frac{dX_K}{X_K} + \frac{dw_K}{w_K} \right) = \left(1 - \frac{1}{\mu} \right) \left[\frac{dY}{Y} + \frac{dP}{P} - \left(\frac{dK}{K} + \frac{dw_K}{w_K} \right) \right].$

Using the differential calculus for two variables, we can observe that our NSR is the approximation of the following equation: $\Delta \ln(Y \cdot P) - \sum_i \theta_i \Delta \ln(X_i \cdot w_i) - (1 - \sum_i \theta_i) \Delta \ln(K \cdot w_K) = \left(1 - \frac{1}{\mu} \right) [\Delta \ln(Y \cdot P) - \Delta \ln(K \cdot w_K)]$, and estimating the expression $\left(1 - \frac{1}{\mu} \right)$ we can finally obtain μ .

The second method applied concern single input margins and it was developed by Rotemberg & Woodford (1999). Because marginal cost of increasing production by increasing any of the production factors should be equal, markups may be measured using only the one chosen. The source of such a reasoning lies in the fact, that: $MRP_i = MR \cdot MP_i$, where MRP_i is a marginal revenue of production factor i , and MP_i is a marginal product of production factor i (see Samuelson & Marks, 2009, pp. 234-235). Because profit maximization condition is: $MR = MC$, the optimal markup can be expressed as follows: $\mu = \frac{P \cdot MP_i}{MRP_i}$. Consequently, the minimizing cost firm should cover the marginal cost of increasing production, taking into account all possible margins (compare Nekarda & Ramey, 2013, pp. 1-47).

According to Rotemberg & Woodford (1999), the most appropriate measure of marginal cost concerns increasing production by changing labor

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

input, with other costs constant. In particular, they considered the number of hours per worker, which was explained by the fact, that while there are adjustment costs of hanging a number of worker and capital stocks, there are no adjustment costs of changing working hours³. If the production function is as follows: $Y = F(ZhN, \dots)$, where N is a number of workers, Y is an output, Z is a labor augmenting technology, h is a number of hours per worker, and W_A is an average hourly wage, we obtain: $MC = \frac{W_A' h + W_A}{F_1(ZhN, \dots) Z}$, where F is a derivative of production function against effective labor ZhN (see Nekarda & Ramey, 2013, pp. 1-47). We can notice, that in the numerator we have marginal revenue of increasing hours per worker and in denominator – marginal product per worker.

Assuming that production function is of Cobb-Douglas type, and marginal wage equals average wage, we get: $\mu = \frac{P}{W_A / \left[\alpha \left(\frac{Y}{hN} \right) \right]} = \frac{\alpha}{s}$, where α is an exponent in the production function (elasticity of output against labor input), and s is a labor share in production value. The change in inversed labor share indicates the change of markup. Although this method is appropriate for a situation of increasing production by increasing working hours, it was also applied to labor costs calculated with no consideration of working hours, (see Klein, 2011. pp. 1-22). Moreover, markups were approximated by the ratio of price of final product to a labor input price (see Phelps, 1994, pp. 678-711).

Few important problems are connected with labor markups (Nekarda & Ramey, 2013). The first one concerns not including overhead labor, which consists of all activities necessary for firm functioning, which can't be connected with products or services offered by the firm. In other words, these activities don't generate profits directly. Overhead expenses include e.g. costs of accounting, advertisement, insurance, legal fees, taxes, rent, repairs, telephone bills. The second problem is not allowing for elasticity substitution between production factors, whereas the third one concerns using average wages, not marginal ones. Although in the standard New Keynesian literature it was assumed, that average wage is a proper measure of marginal increase in working hours, this assumption was neglected by Bills (1987), who argued, that average wage could increase in average hours per worker because of the costs of overtime hours.

³ This choice can be also explained by the fact, that it is regarded that in the short period capital costs are stable, the cost of materials increases proportionally to the production value, and only labor costs may vary (Samuelson & Marks, 2009, pp. 278-280).

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

Consequently, the labor method was further developed. Rotemberg & Woodford (1999) presented corrections of their method by taking into account: non-Cobb-Douglas production function, overhead labor, marginal wage not equal average wage, costs of labor input adjustment, labor hoarding, and variable capital utilization. An attempt of omitting some of these problems and applying the results to real data was undertaken by Nekarda & Ramey (2013).

Moreover, Rotemberg & Woodford (1999) analysed three single input markups measures, alternative to labor markups. The first one was indirect inputs, like energy and materials. The conditions for its use were, that the production technology can't utilize these inputs proportionally to the primary production factors (see Basu, 1995, pp. 512-531), and that there are no adjustment costs. What is interesting, came to the conclusion, that if a production function is isoelastic with respect to labor and materials, a markup is proportional to the both labor share and materials share, so both shares should move proportionally to each other, and their sum should be a multiple of a markup (see Domowitz et al., 1986, pp. 1-17). The second one was stocks of final goods, where it was assumed, that for the firm minimizing costs, marginal cost of decreasing stocks has to be equal to marginal cost of additional production. The third one relies on cost of capital stocks including adjustment costs.

Because of a lack of data on working hours and because we have some doubts if firms in our converging economy actually equalize the marginal cost of rising output across all possible margins, the Roeger markups were assumed as the reference indicators of market power execution in the Polish food sector. Consequently, in order to answer the question if labor markups changes were good indicators of market power execution changes in the Polish food sector in the period 2003-2012, the changes in labor markups will be compared with results received with the Roeger method.

Polish food sector in the period 2002-2013

Individual or sectorial approaches may be distinguished regarding markups calculation (compare Nekarda & Ramey, 2013, pp. 1-47). The first one relies on the data from individual entities coming from the firms financial statements and the sectorial data concerns separate branches or sectors of the economy. The major advantage of the first one is their appropriateness for the impulse reaction analysis, that is monetary shocks or government spending shocks because of their higher frequency, whereas

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

the second one enables to take advantage of the instruments identifying demand and supply shocks typical for a certain branch. There is also the third option concerning aggregation of individual data to the branch level. In our analysis, because of the data confidentiality, we could only get the data of the third type. They come from the F-01 financial statements prepared by the companies hiring more than 9 workers at the end of the fourth quarter and concerning the whole calendar year on the voluntary basis.⁴

The way of calculation categories used for markup estimation are presented in table 2. The analysis covered a period 2002-2013. The yearly data were acquired from the IAFE-NRI, and the portal www.obligacjeskarbowe.pl. They cover divisions: 10 – food, 11 – non-alcoholic beverages of section C – manufacturing of the Polish Activity Classification 2007. The data from 11 main groups and 32 classes were analyzed. Regarding labor markups, because of no access to data on working hours in food sector branches, the labor share was calculated as the ratio of labor costs to production value.

Table 2. The data used in the analysis

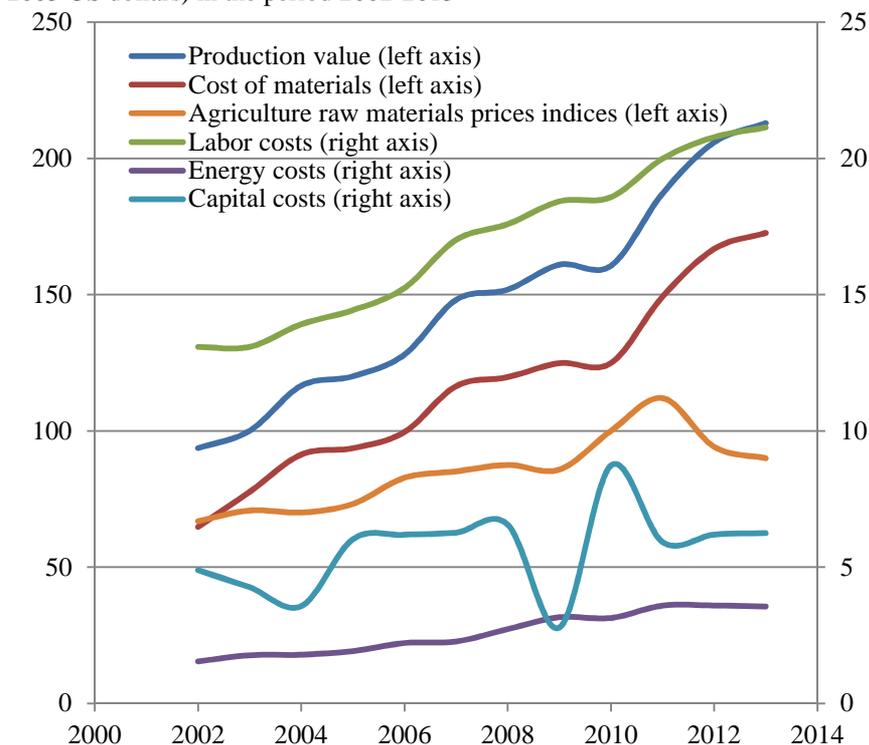

Variable	Characteristics
Production value	Sales revenue adjusted for the change in inventories and taxes levied on the company costs (excise tax, property tax, tax on means of transport and nondeductible VAT)
Materials costs	Costs of materials, external services and commodities and materials purchased for resale
Labor costs	Wages and salaries, social security contributions paid by the employer, other generic costs (staff costs – including travel expenses, death benefit, accident compensation and others, e.g. property insurance)
Energy costs	Extracted as a separate production factor
Capital costs	Instead of the assets value the following value of a flow of capital services in branch i is used: $k_i = (r - \pi + \delta_i) \cdot K_i$, where: r is the rate of return defined as expected return on capital employed in the alternative project, measured by the interest rate of government bonds; π is a value added deflator; δ_i is a depreciation rate (the ratio of depreciation to the assets value); K_i is the fixed and intangible assets value (see Jorgenson & Griliches, 1967, pp. 249-283; Oulton and Srinivasan, 2003, pp. 1-88)

Source: own elaboration based on the Gradzewicz & Hagemajer (2007b, pp. 11-27)

⁴ Because some of the needed categories are lacking in this statement, we were forced to calculate them in an indirect way.

Figure 3 presents the values of each category, as well as agricultural products prices indices. Table 4 presents main characteristics of the data.

Figure 3. Production value and costs of production factor costs (in mln zł) in the Polish food sector and prices of the world agricultural products (2010=100, real 2005 US dollars) in the period 2002-2013

Source: own calculations based on IAFE-NRI (2014), www.obligacjeskarbowe.pl.

Although food sector in Poland is often treated as traditional one and of diminishing importance, we could observe the enormous growth of the production value of analysed companies in the period 2002-2013. In 2013 it reached its maximum of 212.93 mln zł. Comparing with 2002, it was a growth by 127.22%. The main reason was undoubtedly joining the EU and export growth. It should be noticed, that in the period 1995-2013 export of the whole Polish agro-food sector increased from 3 to 14 bln euro, and for example in 2012 almost 77% of it went on the EU markets (see Łopaciuk, 2013, pp. 7-14).

Table 4. Main characteristics of analysed categories

Item	Production value	Cost of materials	Labor costs	Energy costs	Capital costs
Mean (in mln zl)	148.83	116.81	16.94	2.61	5.64
Minimum (in mln zl)	93.71	64.82	13.08	1.55	2.79
Maximum (in mln zl)	212.93	172.65	21.14	3.59	8.73
Coefficient of variation (in %)	25.17	27.66	16.61`	28.57	26.54
Growth (in %)	127.22	166.37	61.58	129.85	27.97
Yearly growth (in %)	7.34	8.12	4.84	8.42	3.19
Change of share in production value (in %)	-	17.23	-28.89	1.16	-43.68
Variability explained by growing linear trend (in %)	97.37	96.49	98.36	95.92	17.92

Source: own calculations based on IAFE-NRI (2014), www.obligacjeskarbowe.pl.

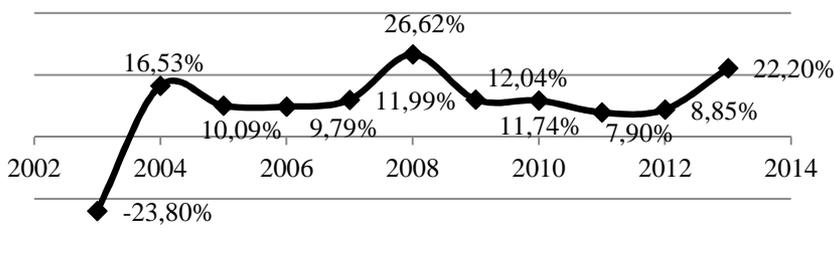

Also all the series of distinguished cost categories can be characterised by growing trends, which explained more than 90% of their variability, apart from capital, changes of which were more of the cyclical character. Comparing to the production value, materials costs were growing in the faster pace, and labor costs were growing one third slower. While energy was increasing the fastest, the weakest growing trend may be observed in capital cost data. Consequently, while the share of the cost of materials in the production value increased, the shares of labor and capital costs decreased.

Looking at the correlations between analysed data series, we can observe that the capital costs correlations with the rest of variables were the weakest (0.34-0.39), whereas correlation between other variables were between 0.95 and 0.99. The drop in capital costs in 2009 may be an effect of the world economic crisis. As early as in 2010 companies seemed to rebuild their capital costs. Simultaneously, with the high worldwide inflation of agricultural products in 2010 and 2011 (of appropriately 0.16 and 0.12), what influenced food prices, the food production value started to increase faster. Moreover, probably because of the higher market uncertainty and restructurings, the pace of rising of labor costs wasn't so high.

Roeger markups

Figure X presents the estimated Roeger markups in the period 2003-2013⁵. The average markup amounted to 1.10, what can be seen as rather moderate. The standard deviation from the mean was also relatively low – 0.12, and the coefficient of variation amounted to 0.11. What is interesting however, elimination of the first observation, which is an outlier, increases the mean to 1.14, decreasing the standard deviation to 0.06 and the coefficient of variation to 0.05. Although since the accession to the EU markups increased by 0.06 (from 2003 it was by 0.46 p.p.), no linear trend was found in the data. Particularly, its negative sign in 2003 was caused by the high increase in costs of materials (agricultural products prices) before the entrance.

Figure 4. Roeger mark-ups (over MC) in the Polish food sector in the period 2003-2013

Source: own calculations based on IAFE-NRI (2014).

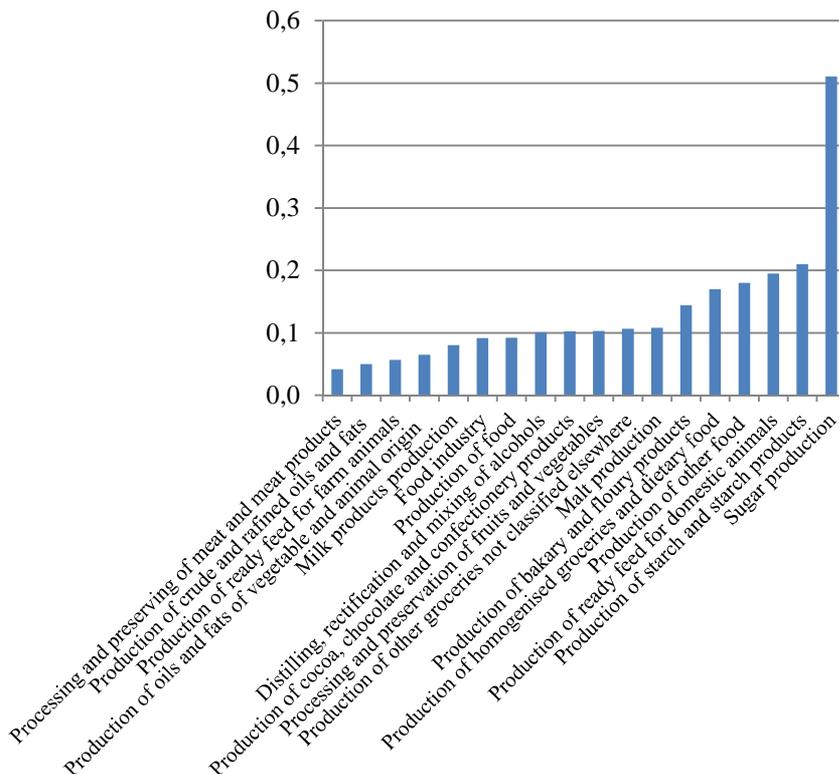

Comparing with the level of the Polish food sector markups estimated for the period 1996-2004 by Gradzewicz and Hagemeyer (2007b), the average Roeger markup over *MC* decreased (from 0.22 to 0.10), and its variability increased (from 0.56 to 1.18). Higher variation of markups could be related with the convergence processes taking place in the Polish economy after entering the EU, as well as with the effects of the 2007 crisis.

Additionally the average markups over *MC* in the food sector branches in the period 2003-2013 were calculated. But only for 18 out of 46 categories the results were statistically significant. They are presented in figure 5.

⁵ Although all the regression results were statistically significant (at the level 0.1), the set of explanatory variables was not always sufficient. Especially in years 2003, 2006, 2012 and 2013 some other factors mattered.

Extremely high markups were observed in the sugar production reaching 0.51. To other relatively high markup include production of starch and starch products (0.21) and ready food for domestic animals (0.20). The lowest markup food industry branches were as follows: processing and preserving of meat and meat products production (0.04), as well as production of crude and refined oils and fats (0.05).

Figure 5. Roeger markups (over MC) in selected branches

Source: own calculations based on IAFE-NRI (2014), www.obligacjeskarbowe.pl.

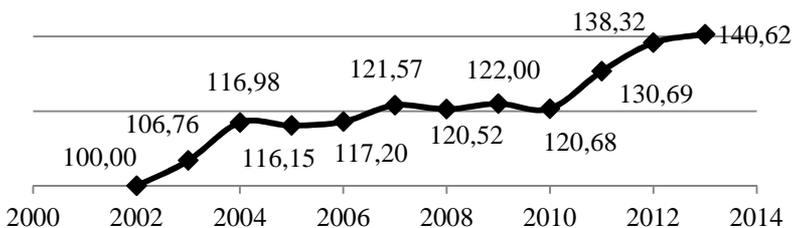

Labor input markups changes

Figure 6 presents the labor markups changes calculated for the period 2002-2013, assuming constant elasticity of output with respect to labor input. The coefficient of variation amounted to 0.09. In the whole period these indexes were increasing on average by 0.025 yearly, what means, that

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

labor markups were increasing by 2.5% yearly, and R^2 amounted to 0.88, what implies the existence of a strong growing trend. Growing labor input markups means that the share of the costs of labor in the value of production was decreasing in the analyzed period.

Figure 6. Labor markups changes in the Polish food sector in the period 2002-2013 (2002=100)

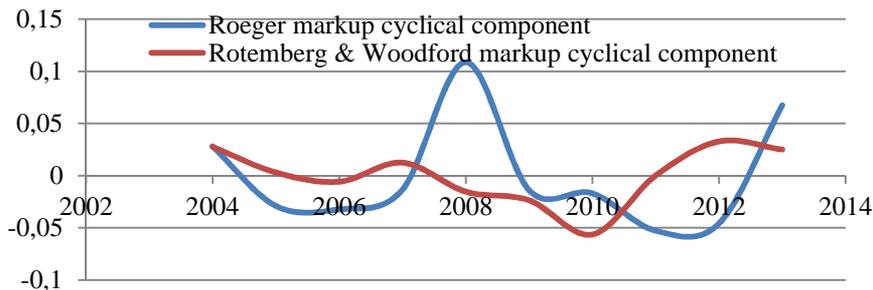

Source: own calculations based on IAFE-NRI (2014).

Three subperiods can be identified: the first one between 2002 and 2004 characterized by the fast increase, the second quite stable between 2004 and 2010, and the third from 2010 to 2013 with again faster increase in labor markups. We suppose the changes were caused by the shocks connected with the EU accession and the world financial crisis. Comparing the labor markup growth with the Roeger markup growth, we can observe, that while the Roeger markups from 2003 increased by 60.36% (and by only 4.86% from 2004), the change in labor markups amounted to 40.62% (20.21% from 2004). Excluding 2003 as the year which stands out (regarding the Roeger markups), we can state, that labor markups change was higher. Consequently, in comparison with Roeger markups, the Rotemberg & Woodford markups seem to overestimate the change in the market power execution in the Polish food sector in the period 2004-2012. This could mean that the assumption of constant elasticity of output with respect to a labor input may not be appropriate for this period (it decreased) and the positive change in labor productivity in the Polish food sector after joining the EU took place.

Moreover, in order to assess, if our labor markups changes were good indicators of market power changes in the Polish food sector, we compared their variability with the one of the Roeger markups (data in logs) in the period 2004-2013. The results are presented in figure 7. It appeared, that the correlation between the data is very weak and it amounted to 0.04. Surprisingly, it was very high until 2007 (0.96) and in the period 2008-2013 it amounted to 0.01. These results might show then, that the Rotemberg and

Woodford markups changes is quite relevant for the part of the analyzed period. The discrepancies regarding period 2008-2013 might indicate that the wages in the Polish food sector were too rigid in this period and should have grown faster, what could be a sign of unions weaknesses in the Polish food companies.

Figure 7. Detrended Roeger and labor markups in the period 2004-2013 (HP filter)

Source: own calculations based on IAFE-NRI (2014), www.obligacjeskarbowe.pl.

Conclusions

The main aim of the article was to depict changes of monopolistic markups in the Polish food sector in the period 2002-2013 as indicators of the market power execution. The theoretical background was presented in order to prove that the markup can be considered as a symptom of market power. The Roeger and Rotemberg & Woodford methods were applied. The average Roeger markup (above MC) amounted to 0.10, what can be seen as rather moderate and in 2013 it equaled 0.22. The differences in results for the branches indicate a substantial heterogeneity in the Polish food industry companies pricing practices.

Because from 2004 to 2012 the change in Roeger markups (+4.86%) was lower than in the labor markups (+40.62%), the labor markups changes seems to overestimate the change in market power execution in the Polish food sector. Also because of weak correlation between detrended series, we considered simple inversed labor input as insufficient indicator of the market power execution changes in the Polish food sector in the period 2004-2013. The application of this method for the Polish condition needs further improvements, e.g. additional data on hours per worker are needed (no adjustment cost), and the values of elasticity of output with respect to labor input will enable calculation of absolute markups values. Additionally, the

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

following possible amendments should be included: CES production function, overhead labor, marginal wage. Nevertheless, because of the restructurings in the Polish food sector and because of the crisis, the assumption that a cost minimizing firm equalizes the marginal cost of rising output across all possible margins may be too strong.

Regarding data, some drawbacks should be here highlighted. Firstly, the main obstacle was no access to data on the firm level and consequently no possibility to clean the database. Secondly, the data frequency was too low (yearly basis) to analyse the cyclical proprieties of markups.

Finally, some rather general conclusions regarding competition policy in the food sector can be formulated. It should still focus on the antitrust laws execution, but most effort should be put on creating strategic trade policy, which will contribute to broader and faster development of the Polish food sector and especially to the more intense international trade promotion. Regarding regulation and deregulation, a special focus should be put on regulations promoting vertical arrangement between firms as well as vertical integration, both in the framework of the CAP and the national agricultural policy. In particular, special attention should be paid to the concentration processes and pricing practices in the production of sugar starch and starch products, ready food for domestic animals, homogenized groceries and dietary food, as well as bakery and floury products.

Public-private Mix and Performance of Health Care Systems in CEE and CIS Countries

JEL Classification: *I11; H51; P36*

Keywords: *health care system; public-private mix; transition economies, health status*

Abstract: The role of the public and private sector in health care systems remains one of the crucial problems of these systems' operation. The purpose of this research is to identify the relationships between the performance of health systems in CEE and CIS (Central and Eastern Europe and Commonwealth of Independent State) countries and the mix of public-private sector in the health care of these countries.

The study uses a zero unitarization method to construct three measures of health system performance in the following areas: (1) resources; (2) services; and (3) health status. The values of these measures are correlated with the share of public financing that represents the public-private mix in the health systems.

The data used is from World Health Organization's *Health for All Database* for 23 CEE and CIS countries and comprises the year 2010.

The results show that the performance of health systems in the countries investigated is positively associated with a higher proportion of public financing. The strongest relationship links public financing with performance in the area of services production. For policy makers, these results imply that health systems in post-communist transition economies could be susceptible to a decreasing role of the state and that growing reliance on the market mechanism in health care can deteriorate the operation of these systems.

Introduction

The role of the public and private sector in developed economies seems to be one of the crucial problems in both economic policy and research agenda. Health care systems are not free from dilemmas concerned with the extent to which the government and market should run their operation. The growing pressure on public finance of contemporary welfare states has led to increased importance of market mechanism in health care systems over the last 25 years. Privatization processes, introduction of managed care and internal market as well as increasing private health financing are some examples of this trend. The expectations behind these market-enhancing policies were to restrain growth in health expenditure and to introduce the vital forces of competition into health care, traditionally dominated by public economics thinking. Nowadays, it is clear that the reinforcement of private mechanism has not led to improved control over health care spending and one of the side effects of market oriented reforms is a problem of health inequities. Currently, the question of appropriate public and private roles in health care is still far from being answered and the claim of Saltman (2003, p. 24) that "...one of the most striking aspects of this public-private debate is that it never seems to be finally settled" describes the state of present policy and research debates in the area of health care.

This study attempts to contribute to the debate on the role of public and private sectors in health care by investigating whether the public-private mix in health care financing is associated with the performance of health systems. To do so, data from 23 transition economies of Central and Eastern Europe (CEE) and Commonwealth of Independence States (CIS) is used. The way the public-private mix influences the operation and performance of health system is subject to heated debates and extensive literature on the topic has been published. However, a vast majority of these contributions focus on highly developed economies, usually OECD member states (see e.g. Götze, Schmid, 2012; Holden, 2005; Rothgang, Cacace, Frisina, & Schmid, 2008; Rothgang, Cacace, Grimmeisen, & Wendt, 2005; Touhy, Flood, Stabile, 2004). The intention of this research is to shed more light on the topic by analyzing relationships between the magnitude of public/private sector and the performance of health care in transition economies context.

The paper is organized as follows. The introductory part of the paper describes the motivation behind the paper and provides context for the study. Next, in the theoretical section, the public-private dichotomy in

health care context as well as the concept of health care system performance are briefly discussed. In the third section, the results of the empirical analysis are reported and discussed. The last section concludes the paper and provides future research directions.

Theoretical background

There are two theoretical issues to be discussed here in order to clarify the concepts used in the empirical analysis. First, the problems of ownership and public-private distinction are considered; after that, a brief discussion of health care system performance is provided.

Public and private sector in health care

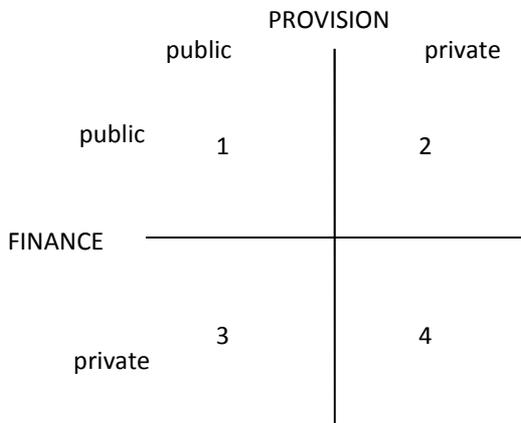

There is no single and unambiguous meaning or definition of public and private domains in health care context. The ambiguity is caused by a great complexity of health care systems that cannot be captured in a straightforward model describing ownership issues. Consequently, a reliable taxonomy of public and private spheres is difficult to construct and classifications used often do not follow the dynamics of modern health care systems.

Simplifying the reality of these complex interactions, one can use the Donaldson's and Gerard's model of the public/private mix in health care financing and provision (Donaldson & Gerard, 2005, p. 57). Figure 1 illustrates how public or private financing of health care can be accompanied by public or private provision of services.

Quadrant 1 represents the pure public sector in which public providers are publicly financed and segment 4 describes private delivery that is financed privately. The point is that in health care public finance does not match public provision in each case and private delivery does not have to be financed privately. Private provision accompanied with public provision (segment 2) as well as public delivery financed privately (segment 3) both represent the mixed sector (Donaldson & Gerard, 2005).

In fact, the public-private dichotomy in health care is not limited to the financing and provision dimensions. Maarse (2006) discerns the public and private dimensions also in the management and operation as well as in investment areas, while Rothgang, Cacace, Grimmeisen, and Wendt (2005) distinguish also a regulation aspect of the public-private mix.

Figure 1. Public-private mix in health care financing and delivery

Source: Donaldson & Gerard (2005, p. 57).

Therefore, the complexity of the ownership problem in the health care context brings conceptual confusion and makes the definitions of 'private' and 'public' ambiguous and contextual. What is private, particularly, is difficult to define as the arrangements in the private sector range from private-for-profit, through self-employment to private-not-for profit and each of the above can be extensively financed and/or regulated publicly (WHO, 2002). In fact, the phenomenon called 'melting of public-private boundaries' is increasingly observed with new schemes combining public and private elements and where the public and private domains are not easily distinguishable (Maarse, 2005; Saltman, 2003). As a consequence, the application of the public-private dichotomy to empirical analyses in health care depends on data availability and, inevitably, simplifies the complex phenomenon of ownership.

Performance of health care systems

The performance of an economic organization is usually defined in terms of achievement of some specified objectives. Thus, the performance of health care systems should refer to the goals of these systems.

According to WHO a health system consist of all the people and actions whose primary purpose is to improve health (WHO, 2000). In practical applications, this wide definition is often restricted to those activities that

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

refer to formal health care activities and exclude actions from other than health care industries.

There is ongoing debate on the objectives of health systems. Probably, the most prominent approach to the issue is the one of WHO. As it is maintained by this organization, there are three main goals of health systems: (1) health, (2) responsiveness, and (3) fairness in financial contribution (Murray & Frenk, 2000, p. 719). In other words, health systems to meet their goals should deliver effective, preventive and curative health services to a whole population, equitably and efficiently, and protect individuals from catastrophic health care expenses (Kruk & Freedman, 2008, p. 264). The defining goal of health systems is to maintain and restore health both in terms of average health status improvement and health inequalities reduction. Responsiveness, the second intrinsic goal defined by WHO, refers to respect for the people interacting with the system as well as client orientation. The third goal, fairness in financial contribution, means that the operation of health systems should not lead households to impoverishment when in need of obtaining necessary health care and that poor households ought to contribute to the health system less than rich households do.

Translating these goals into operational measures that could be applied internationally is a complex issue and it was only once when WHO approached the problem constructing a composite index of health system performance (WHO, 2000). Thenceforth, the authors aiming at assessing the performance of health care systems focus rather on single aspects of health system operation. The performance dimensions that are usually evaluated are effectiveness in outcomes (health status, patient satisfaction) and outputs (access to and quality of care); equity in outcomes (health status of disadvantage groups, fair financing and risk protection) and outputs (access to and quality of care for disadvantaged groups) as well as efficiency in outcomes (value of resources) and outputs (adequacy of funding, costs and productivity, administrative efficiency) (Kruk & Freedman, 2008, p. 267-268).

In this research, selected categories of health system performance in CEE and CIS countries are chosen, based on the data availability; the details are provided below.

Methodology of the research

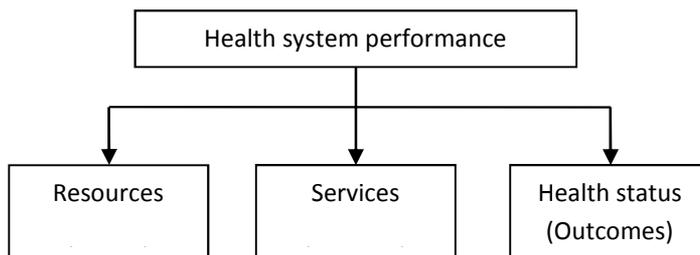

The empirical analysis in the paper consists of two stages. First, the performance of health care systems in CEE and CIS countries is assessed. In

this stage, three measures of health system performance are constructed and their values are calculated for each country. In the next step, the values of these performance indices are correlated with a variable measuring the public-private mix of health care. A detailed description of methodology (variables, methods, time span of the analysis and data source) is provided further in this section.

The performance of health care systems is described in three dimensions, namely, their inputs, outputs and outcomes. This approach draws on Donabedian's structure-process-results approach (Donabedian, 1988, p. 1745-1746) and a health production model which links health care inputs through outputs to health outcomes (Cumming & Scott, 1998, p. 55). The study follows a framework used in the recent paper focusing on health systems of OECD member states (Tchouaket, Lamarche, Goulet, & Contandriopoulos, 2012).

Figure 2 presents a conceptual approach to health system performance assessment applied here.

Figure 2. Conceptual approach to assessing performance of health care systems

Source: own work.

Three synthetic measures are constructed in order to evaluate the performance of health systems in each of the three above aspects separately. The construction of one general index that would combine all three aspects of health care seems not to be well-grounded in health policy theory.

As it is discussed above, the concept of health system performance is multidimensional and its investigation requires using appropriate methods. Here, zero unitarization method (Kukuła, 2000), which is a multivariate analysis technique, is used to incorporate the multidimensional nature of health systems.

The method allows for constructing a synthetic development measure which is characterized by some specific properties; it combines the speci-

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

ficity of individual variables that it is built of, and reflects the investigated phenomena thoroughly (Młodak, 2006, p. 119). The method is based on the variables normalization procedure and is considered to be one of the simplest methods of synthetic measure construction, and one that is characterized by desired properties¹.

The method requires assigning variables to stimulants or destimulants. The former category groups those variables in which case the higher values are preferred over lower values, while in the case of the latter, lower values have preference over higher ones. For the sake of brevity, the formal procedure as well as calculation formulas are not shown here and they can be accessed elsewhere (see e.g. Kukuła, 2000; Kukuła, 2012; Młodak, 2006).

There are numerous indicators that allow to describe health care in terms of inputs, outputs and outcomes and their selection usually depends on data availability. The data for this analysis has been taken from World Health Organization's *Health for All Database* (WHO, 2014), an online database that collects information on various aspects of health systems in European countries. The analysis covers 23 countries of Central and Eastern Europe as well as some members of the Commonwealth of Independent States. The time span is limited to year 2010 solely, however, in cases of missing data, data from the nearest year (not earlier than 2007 however) is used.

The first step of the empirical procedure is to select variables according to data availability. Table 1 presents the initial set of variables selected with the use of this criterion. Potentially, more measures could be included, unfortunately, the data constraints prevented from doing so. The table also shows which of the variables are stimulants and which destimulants.

The resources employed in the health care systems were measured in physical, human and monetary terms. The physical resources were proxied by densities of hospitals and hospital beds; unfortunately the data on measures of technologically advanced equipment (e.g. magnetic resonance imaging or computer tomography scanners) is not available. The human resources were represented by two most common used indicators, i.e. densities of physicians and nurses. Of the monetary measures used, two were defined as stimulants and these were expenditure on health, expressed both as a share of GDP and in US dollars. On the other hand, two measures of out-of-pocket payments were classified as destimulants, because a higher

¹ It ignores units of measurement allowing for the comparison of diverse variables; it is characterized by equal variation range for all normalized variables [0,1]; it allows for normalizing positive, negative as well as zero values (compare Kukuła, 2000, pp. 81, 107).

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

share of direct private payments puts households at greater risk of catastrophic health expenditures.

The services produced in the health care systems were measured using inpatient care discharges and outpatient contacts. These were supplemented with five disease-specific discharges adjusted for mortality rates as well as with shares of infants vaccinated against four diseases. Each of the above services indicators was classified as a stimulant.

The population health status was proxied by demographic and epidemiological measures based on mortality and morbidity data. Life expectancies, infant and maternal mortality rates and standardized death rates are considered to be the best choice in international health status comparisons (Bonita, Beaglehole, & Kjellström, 2006, ch. 2; Murray, Salomon, & Mathers, 2000), while the incidence of three ailments reflects problems caused by communicable (tuberculosis and HIV) and non-communicable (cancer) diseases. Of the health measures, all but life expectancy measures were classified as destimulants.

Table 1. Definitions of variables used in the construction of synthetic measures

HEALTH CARE RESOURCES EMPLOYED	
<u>Stimulants:</u>	
R1:	Hospitals (number per 100.000 population)
R2:	Hospital beds (number per 100.000 population)
R3:	Physicians (number per 100.000 population)
R4:	Physicians per 100 beds (number)
R5:	Nurses (number per 100.000 population)
R6:	Total health expenditure as a share of gross domestic product (%)
R7:	Total health expenditure in US dollars, adjusted for purchasing power parity (US\$)
<u>Destimulants:</u>	
R8:	Share of out-of-pocket payments in total health expenditure (%)
R9:	Share of out-of-pocket payments in private health expenditure (%)
HEALTH CARE SERVICES PRODUCED	
<u>Stimulants:</u>	
S1:	Inpatient care discharges per year (number per 100)
S2:	Outpatient contacts per year (number per person)
S3-S7:	Hospital discharges adjusted for by-cause mortality*: (S3) neoplasms; (S4) circulatory system diseases; (S5) ischeamic heart disease; (S6) <i>cerebrovascular diseases</i> **;; (S7) respiratory system diseases (number per 100.000)
S8-S11:	<i>Share of infants vaccinated against: (S8) diphtheria; (S9) tetanus; (S10) pertussis; (S11) measles (%)</i>

HEALTH STATUS ACHIEVED

Stimulants:

H1-H2: (*H1*) Female and (*H2*) male life expectancy at birth (years)

H3-H4: (*H3*) Female and (*H4*) male life expectancy at 65 years (years)

Destimulants:

H5: Difference in life expectancy between females and males (years)

H6: Infant mortality rate (deaths per 1.000 live births)

H7: Maternal mortality rate (maternal deaths per 100.000)

H8-H10: Incidence of (1) tuberculosis; (2) HIV; (3) cancer (number per 100.000 population)

H11: Standardized death rate for all causes and all ages (number per 100.000 population)

* - the study uses hospital discharges divided by mortality by cause. Raw data on discharges should not be used as it not only reflects the availability of services; it also depends on incidence of diseases.

** - *italic text format* – variables excluded from the analysis due to formal reasons (see text for details).

Source: own work.

In the subsequent step, the set of potential variables was limited according to formal criteria required to apply the method efficiently. Firstly, the variation of indicators was investigated in order to exclude the variables characterized by too low variability. For that reasons, the measures of life expectancy (H1-H4) as well as infant vaccination indicators (S8-S11) were excluded, as their coefficient of variation values were lower than 10 percent, usually accepted threshold. Secondly, to avoid duplicating information contained in the selected variables, correlations among potential variables were investigated. Based on the correlation criteria, the measure of (adjusted) hospital discharges caused by cerebrovascular diseases (S6) was excluded as it was highly correlated (over 0,8) with the circulatory system discharges. The reason for excluding the former is that it is of lower magnitude for health care operation than the latter.

In the final step of the empirical analysis, three synthetic measures constructed in the way described above were correlated with the share of public financing in total health expenditure. Public financing was the only measure that allowed for proxying the magnitude of public sector in health care in international context. Obviously this indicator is not without drawbacks, still it reflects the public-private mix in an acceptable way and is widely used in country-level analyses (see e.g. Rothgang et al., 2005). For the purpose of correlation, Spearman rank correlation coefficient is used.

Results and discussion

The results of performance analysis are reported in table 2. The values of the indicators range from zero to one and higher values are interpreted as higher performance of the systems.

The countries with the highest resources availability were Slovenia, Belarus and Russia, while the ones with the lowest performance in this aspect were Bosnia and Herzegovina, Montenegro and Armenia. When it comes to service accessibility the group of top countries includes Belarus, Lithuania and Ukraine, whereas low services production characterized Kazakhstan, Armenia and Azerbaijan. The health status synthetic measure values place Bosnia and Herzegovina, Slovenia and TYFR Macedonia at the top of the healthiest nations rank; Ukraine, Russia and Kazakhstan were characterized by the poorest population health.

The results suggest that countries differ in the way they transform their health care resources and services to health status improvement. Some countries employed relatively abundant resources and used them relatively efficiently obtaining a good health status (see e.g. Czech Republic, Poland, Slovenia and Slovakia). There were also countries, however, the societies of which benefited from good health with little resource utilization and production of services (see e.g. Croatia, TYFR Macedonia, Azerbaijan). Conversely, some countries that performed well in terms of resources and service availability failed to transform these into the health improvement of their populations; the examples are Belarus, Estonia, Lithuania, Russia and Ukraine.

Source: own calculations based on WHO (2014).

Two conclusions can be drawn from the above differences in the inputs-outputs-outcomes transformation in particular countries. Firstly, the differences seem to reflect the efficiency variation among the CEE and CIS countries' health care systems. The countries with low (high) resources and/or low (high) services utilization that were simultaneously characterized by good (poor) health status probably are the ones with relatively efficient (inefficient) health care systems. Secondly however, good health status in particular countries may result from factors other than health care, i.e. a higher income level and lower income inequalities, a higher education attainment, health-enhancing life style, better housing and working conditions. In this research these health affecting factors were excluded from analysis, still, one can presume that the differences in efficiency of health care system among CEE and CIS countries are the case.

The final stage of the analysis shows a relationship between the performance of health care systems in the group of countries and the magnitude of public sector in these systems. The share of public financing in total health expenditures represents the public-private mix.

The three following figures (3, 4 and 5) show scatter plots illustrating the associations between the three measures of performance and the proportion of public financing.

Figure 3. The association between health care resources synthetic measure and the share of public financing

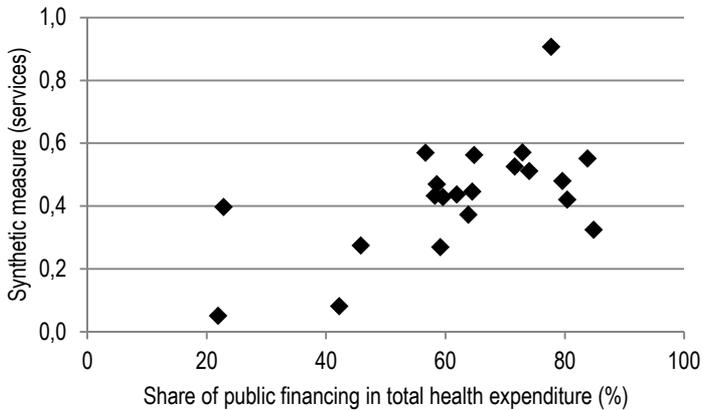

Note: The value of the Spearman rank correlation coefficient is 0,296 ($p = 0,17$).
Source: own calculations based on WHO (2014).

There is a positive but quite weak association between the resource dimension of health systems performance and the share of public financing in CEE and CIS countries ($\rho = 0,296$; $p = 0,17$). The value of Spearman rank correlation is not statistically significant, however, it still suggests that public financing could be positively associated with the performance of health system in the area of resources availability.

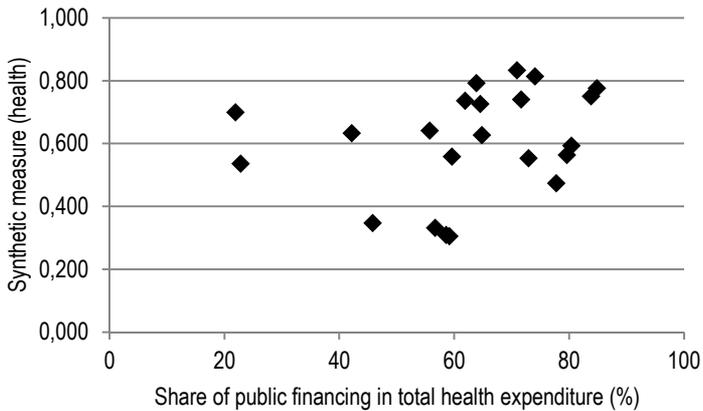

The correlation between health system performance in the area of services produced and the extent of public financing, is also positive and the association is quite strong ($\rho = 0,482$; $p = 0,03$). What is more, the value of correlation coefficient is statistically significant. The positions of marks on the scatter plot (figure 4) suggests that an increment in the share of public financing is related to a quite high improvement in the (services) synthetic measure. It remains in contrast to the previous graph (figure 3), where, there is a slight variation in the (resources) synthetic measure with a growing share of public financing.

Figure 4. The association between health care services synthetic measure and the share of public financing

Note: The value of the Spearman rank correlation coefficient is 0,482 ($p = 0,03$).
Source: own calculations based on WHO (2014).

Figure 5. The association between health status synthetic measure and the share of public financing

Note: The value of the Spearman rank correlation coefficient is 0,381 ($p = 0,08$). After removing the case with outlier value (Azerbaijan) the value of correlation coefficient grows to 0,440 ($p = 0,05$).
Source: own calculations based on WHO (2014).

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

The correlation between the health status performance of the CEE and CIS countries and the share of public financing is also positive ($\rho = 0,381$; $p = 0,08$) and the relationship is moderate. After removing the outlier case (Azerbaijan) the value of the correlation coefficient becomes statistically significant ($\rho = 0,440$; $p = 0,05$).

Conclusions

The purpose of the empirical analysis was to estimate the performance of health care systems in the transition economies of CEE and CIS countries and to establish possible relationships between the performance of these systems and the magnitude of the public and private sector in their operation. The performance of the health systems was assessed using three synthetic measures describing: (1) the resources employed; (2) services produced; and (3) health status achieved.

The results show that the countries differ in terms of their systems' performance. Generally, the wealthier countries are characterized by high performance in both the resources availability and health status. The other ones, however, engage less than average resources and produce quite little services, but still are able to achieve a good health status. On the other hand, the former Soviet republics are the countries that fail to achieve a good population health status, despite quite abundant resources in most of the cases.

When it comes to the relationships between the magnitude of public sector in the health systems and their performance, it was shown that the share of public financing is positively associated with the performance in all the three investigated areas. The strength of the relationships was varied, but still the correlations proved to be significant in two of the three cases. To sum the discussion up, one can conclude that public financing is positively related to the performance of the health care systems in the region of CEE. The conclusion has important policy implications, suggesting that the states should not decrease their involvement in the operation of their health systems. Otherwise, the performance of these systems would be put at the risk of malfunctioning and, consequently, deteriorate the health status of the populations.

Before concluding, a limitation of this study needs to be outlined. Here, the public-private mix of health care is described only in terms of health care financing and no other dimension of this mix (delivery, investments, and regulations) is investigated. The shortcoming is caused by data re-

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

strains. No systematic and comparable data on the public-private structure of providers is available. Also, statistics concerning the investments ownership structure in the group of CEE and CIS countries are non-existent. The data on the regulation is qualitative in nature and is also uncollectable for the group of the investigated countries.

The study results suggest many possibilities for future research. The investigation of health system operation in the post-communist transition economies could be extended by e.g. efficiency analyses and grouping countries of similar characteristics.

**Fiscal Sustainability in CEE Countries – the
Case of the Czech Republic, Hungary
and Poland***

JEL Classification: *E62; H62; H63*

Keywords: *fiscal sustainability; monetary and fiscal dominance; primary balance; debt; cointegration*

Abstract: The aim of the study is to assess fiscal sustainability in the Czech Republic, Hungary and Poland and to test for existence of fiscal dominance in these countries in the context of the fiscal theory of the price level. The empirical study is conducted using unit root tests and cointegration analysis with possible structural breaks. The approach is consistent with so called backward-looking approach for fiscal dominance testing proposed by Bohn (1998). The results suggest that in the Czech Republic and Poland fiscal dominance prevailed in the analyzed period, while in Hungary – monetary dominance. The result for Hungary may be caused, however, by a one-time reduction in debt resulting from changes in pension system.

Introduction

During and after the global financial crisis many countries saw a significant loosening of fiscal policy. Considering that in many European countries public debt levels were already high even before the outburst of the crisis, the worsening of the public finances raised questions about the sustainability of the fiscal policy. In this context, also concerns have arisen about the consequences of fiscal imbalances for the effectiveness of monetary policy. As the “unpleasant monetarist arithmetic” by Sargent and Wallace (1981) shows, price stability requires an appropriate fiscal policy. If the public debt is too high, the monetary authorities will finally lose control over inflation. This concept has been further developed by the fiscal theory of the price level (FTPL). FTPL claims that the intertemporal government budget constraint may be satisfied (that means that the fiscal solvency condition may be fulfilled) in two ways: through adjustment of the primary surplus – which is called the Ricardian or monetary dominant regime, or through the endogenous adjustment of the price level – which is called the non-Ricardian or fiscal dominant regime. Therefore, the fiscal imbalances and the lack of adjustment of the fiscal policy may threaten the overall economic stability.

The aim of the paper is to test for fiscal sustainability and fiscal dominance in three CEE countries: the Czech Republic, Hungary and Poland over the period Q1:2000 – Q3 2013. The test consists in analyzing the statistical properties of the fiscal variables time-series and the long-term relationship between primary surplus and public debt, as described below in detail. Although the fiscal situation varied across the countries, the public debt rose in all of them substantially over the analyzed period. Therefore it seems important to test for the presence of fiscal dominance, for it may undermine the ability of the countries’ central banks to achieve their inflation targets.

The paper is organized as follows. In the next section we refer to the fiscal theory of the price level as the theoretical guidelines how to distinguish between monetary dominance and fiscal dominance. In the third section empirical methodology is described in detail. The fourth section presents the countries’ recent fiscal policy developments and results of the empirical study of the long-term relationship between governments primary balance and debt. Finally, last section offers some concluding remarks.

Theoretical background

The fiscal theory of the price level states that, in general, a proper monetary policy is not sufficient to ensure the stability of the price level. The price stability also requires an appropriate fiscal policy. This possibility first formulated Sargent and Wallace (1981) in their “unpleasant monetarist arithmetic”. They showed that if the government finances its debt from taxes and seignorage, too loose fiscal policy may force the central bank to increase seignorage, in order to guarantee the fulfillment of the government budget constraint. In consequence, this would lead to higher inflation. FTPL (Woodford, 1994, 1995, 1996, 1998, 2001; Sims, 1994, 1999; Leeper, 1991; Cochrane, 2000, 2001) develops this concept.

In order to obtain the fiscal solvency conditions, we can write the intertemporal (present-value) government budget constraint:

$$b_t = \sum_{i=0}^{\infty} \left(\frac{1+y}{1+r} \right)^{i+1} E_t s_{t+i+1} + \lim_{i \rightarrow \infty} \left(\frac{1+y}{1+r} \right)^{i+1} E_t b_{t+i+1} \quad (1)$$

where b denotes public debt in relation to GDP, s – primary surplus to GDP, y – growth rate of real GDP, r – real interest rate and E is a expectations operator. Both y and r are assumed to be constant.

Therefore, we can write the condition for fiscal solvency as:

$$\lim_{i \rightarrow \infty} \left(\frac{1+y}{1+r} \right)^{i+1} E_t b_{t+i+1} = 0 \quad (2)$$

which means that the present value of the public debt must approach zero in infinity for the fiscal policy being sustainable, or:

$$b_t = \sum_{i=0}^{\infty} \left(\frac{1+y}{1+r} \right)^{i+1} E_t s_{t+i+1} \quad (3)$$

which means that the current debt must be equal to the sum of expected future primary surpluses expressed in present value term. The two conditions are, of course, equivalent (based on Bajo-Rubio et al., 2009).

According to the FTPL to regimes may be distinguished, depending on the way the fiscal solvency is guaranteed. In the Ricardian, or monetary

dominance regime, fiscal policy adjusts in such a way, that the intertemporal government budget constraint is satisfied, regardless of the price level. In contrast, in non-Ricardian, or fiscal dominance regime, fiscal policy is conducted in such a way that the intertemporal budget constraint would not be satisfied for all possible price levels. (Christiano and Fitzgerald, 2000) In this situation the price level is endogenous and adjusts to ensure fiscal solvency. We can rewrite equation [3] to illustrate this:

$$\frac{B_t}{P_t Y_t} = \sum_{i=0}^{\infty} \left(\frac{1+y}{1+r} \right)^{i+1} E_t s_{t+i+1} \quad (4)$$

where B denotes the public debt in nominal terms, P is the price level and Y is the real GDP.

If all other variables, in particular B, s and Y, are set, the only possibility for the government budget constraint to be satisfied is the adjustment of P. Therefore, according to FTPL, even delegating monetary policy to an independent central bank with strong mandate for price stability, like in inflation targeting countries, may be not sufficient to ensure the price level to be really stable.

Methodology

The tests for the fiscal dominance conducted in the spirit of the fiscal theory of the price level may be divided into two approaches: the, so called, backward-looking approach and the forward-looking approach. The backward-looking approach, formulated by Bohn (1998) and Bohn (2007) implies that in a monetary dominant (Ricardian) regime, an increase in the past levels of the public debt would lead to a larger present primary surplus, to ensure solvency. And vice versa – in the fiscal dominant (non-Ricardian) regime we would not expect to observe such a relationship. The other approach, namely forward-looking approach introduced by Canzoneri, Cumby and Diba (2001), postulates that in a Ricardian regime a larger primary surplus today would cause a reduction in the future levels of debt.

In this study the first approach is followed to analyze the fiscal policy sustainability in the Czech Republic, Hungary and Poland and to verify whether in these countries monetary or fiscal dominant regimes prevailed. In the backward-looking approach the long-term relationship between present primary surplus and the lagged public debt is analyzed. In the most

18-19 June 2015, Economics and Finance**

empirical studies the cointegrating relationship between the primary surplus and the lagged level of debt is estimated:¹

$$s_t = \alpha + \beta b_{t-1} + \varepsilon_t \quad (5)$$

where: s_t is the primary surplus to GDP ratio at time t , b_{t-1} is the public debt to GDP ratio at time $t-1$, and ε_t is an error term. The positive and statistically significant values of β ($\beta > 0$) would indicate the prevalence of monetary dominant regime, while $\beta \leq 0$ would indicate fiscal dominant regime.

However, before getting into the cointegration analysis, the properties of the time series have to be checked. Following the methodology applied by Afonso and Jalles (2012), in the first step of our analysis we test for the existence of a unit root in the first-differenced debt time series. This is the simplest test for the fiscal policy sustainability, since an unit root in the first-difference level of debt would indicate that the debt is explosive. Next, we investigate stationarity of the debt and primary surplus time series. Non-stationary and integrated in the same order time series would allow test for cointegration. For the completeness and robustness purposes, several tests for unit root are performed: Augmented Dickey-Fuller, Phillips-Perron and Ng-Perron test. However, in the presence of a structural breaks in the series the above mentioned tests may be biased toward non-rejection of the unit root. Therefore, additionally, two tests allowing for structural break in the series are performed: the Zivot-Andrews (1992) test and the Perron (1997) test. The Zivot-Andrews test allows for one structural break and the break point is endogenously determined from the data.² The null of the test is of a unit root and the alternative hypothesis is of stationarity with structural break. The Perron test also allows for one structural break at an unknown time, but it allows for the structural break to occur under both the null and the alternative hypothesis.

If the test results indicate that the two variables are I(1) process, we can test for existence of cointegrating relationship between primary balance and lagged debt. We use Johansen procedure for this purpose. However, this test does not account for possible structural break, changing the cointegration relationship, which might occur during analyzed period. In this case the test would under-reject the null of no cointegration. Therefore, the Gregory and Hansen (1996) procedure is applied to test for the structural

¹ It is also possible to estimate the cointegrating relationship between government revenues and expenditures in order to test for the fiscal sustainability.

² The break date is selected where the t-statistic from the ADF test is at a minimum.

shift in the cointegrating relationship. The null of the test is of no cointegration and the alternative of cointegration with a break.

If the existence of cointegrating relationship is confirmed, the next step of the analysis is estimation of the parameter β in the cointegration equation. The estimation is made using Dynamic Ordinary Least Squares (DOLS). As discussed above, negative or not statistically significant β would suggest fiscal dominance regime while $\beta > 0$ – monetary dominance regime. However, the positive estimate of β may also be consistent with the fiscal dominance regime, since positive value of β may be observed, when an increase in previous period debt leads to increase in primary surplus (MD regime) but also when a decrease in expected primary surplus leads to decrease in the current debt ratio through a price increase, which is consistent with FD regime (Bajo-Rubio et al., 2009). Therefore, for positive estimates of β , the analysis is complemented by Granger-causality test. Causality running from primary surplus to debt suggest FD regime while causality from debt to primary surplus suggest MD regime.

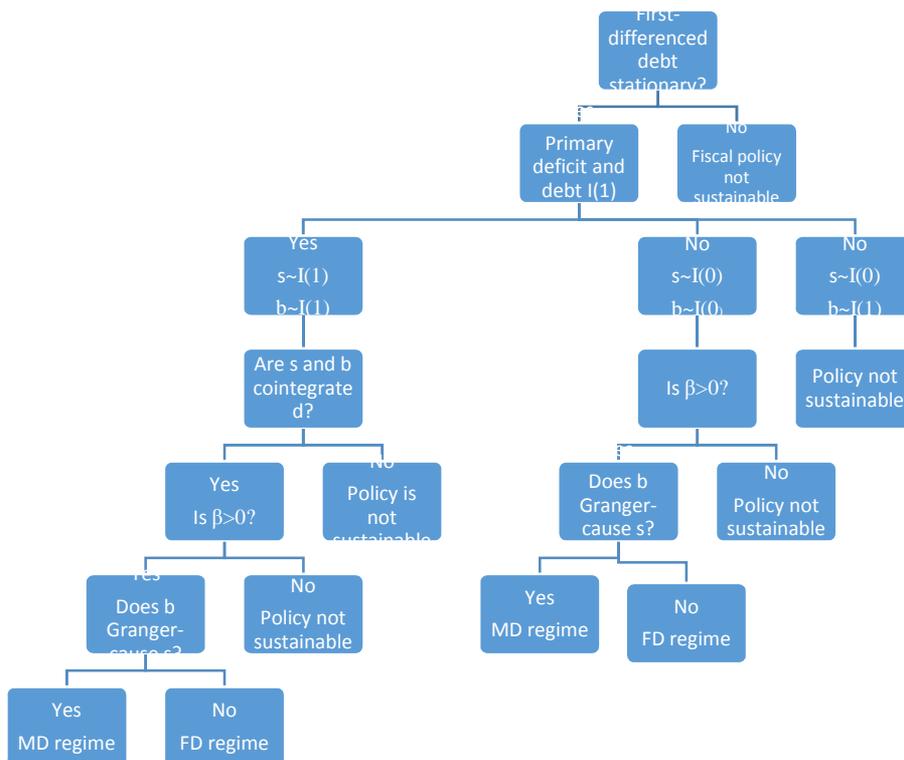

For the cases where both primary balance and the public debt prove to be $I(0)$ processes, we estimate the equation using least squares with breaks. The conclusions regarding the estimates of parameter β are the same as described above.

The procedure for analyzing the fiscal sustainability described above consist of several steps. On each stage of the analysis we can conclude that the conditions for fiscal solvency are not fulfilled. For example, if we conclude that the primary balance and the public debt are integrated of different orders, it would mean that there is no long-run relationship between these two variables (including a positive one) and the fiscal policy is not sustainable. To summarize the description of the methodology used in this study, Figure 1. presents possible results on each stage of the analysis.

The issue of fiscal sustainability in the context of fiscal theory of the price level has been addressed in several empirical studies. Taking approach described above Bajo-Rubio et al. (2009) tested the FTPL for 11 EMU countries over the period 1970-2005. They found that in the countries, with exception of Finland, fiscal policy was sustainable and monetary dominant regime prevailed. More recently, the same authors (Bajo-Rubio et al. (2014)) analyzed relationship between primary surplus and debt for Spain over the period 1850-2000. Their results suggest that although the condition of fiscal solvency was fulfilled, the whole period can be characterized as one of fiscal dominance. Afonso and Jalles (2012) assessed fiscal sustainability in OECD countries over the period 1970-2010, time-series

analysis as well as panel technics. Their results were, however, less optimistic. They found absence of public finances sustainability in the case of most countries, while the Ricardian regime was identified in 12 countries. Legrenzi and Milas (2012) analyzed fiscal sustainability in Greece, Ireland, Portugal and Spain, allowing for non-linearity in behavior of fiscal variables. Their results suggest the existence of a threshold effect: the countries seem to correct their policies only if the unbalances are large.

Figure 1. The sequence of the empirical methodology

Source: Own preparation.

There are very limited number of empirical tests for FTPL for transition economies. Notable example is a study of Komulainen and Pirttilä (2002). They used unstructural VAR models of prices, exchange rate, money and fiscal balance for Bulgaria, Romania and Russia. They stated that their

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

results do not support the existence of fiscal dominance in these countries but the method allows for no clear contradiction of FTPL.

Empirical analysis

Fiscal policy in the Czech Republic, Hungary and Poland

Among countries under consideration most serious fiscal problems experienced Hungary. The public debt ratio was rising from 2001, mostly as a result of deterioration of the primary balance. The public debt to GDP was rising continuously until 2006, when the government realized that the high primary deficit cannot be sustained any longer. Several important measures were implemented in order to improve public finances. As a result of these actions the primary balance became positive in 2008. However, severe economic slowdown caused by the global financial crisis engendered again increase in the debt ratio, magnified by the effect of significant depreciation of forint, which increased the value of debt denominated in foreign currency. Apart from these developments, two important events influenced the public finances in Hungary. Firstly, in 2008, the Hungarian government took out a loan from IMF/EU credit facility, which added 5.5 per cent of GDP to the debt. Secondly, in 2011 a reform of the pension system took place, which resulted in a transfer of 90 per cent of portfolio managed by private pension funds to the Pension Reform and Debt Reduction Fund. Important part of the portfolio consisted of government securities which were withdrawn by the debt management agency. This operation resulted in reduction of the debt by 4.9 per cent of GDP. (Magyar Nemzeti Bank, 2012). At the end of the analyzed period the public debt in Hungary amounted to about 80% of GDP, which was well above the 60% level set in the Maastricht Treaty.

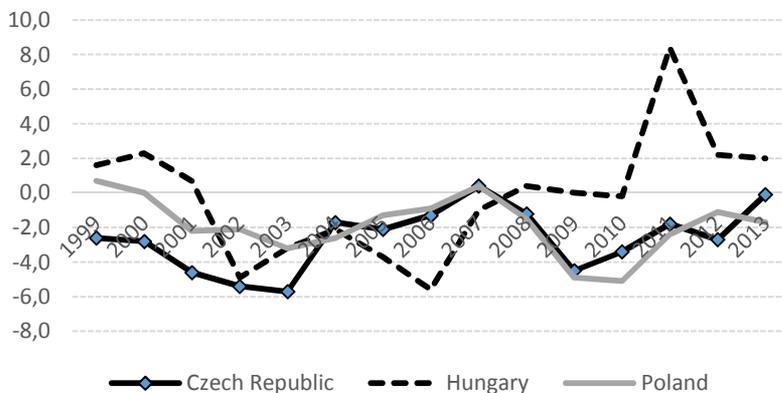

In comparison with Hungary, the public debt level in the Czech Republic may seem low. However, in early 2000s, due to loose fiscal policy and very high budget deficits, the public debt was rising. In 2004, a large Public Finance Reform took place. The fiscal consolidation, which was evenly distributed between expenditure and revenue measures, resulted in decline in fiscal deficit and stabilization of debt. However, in the following years fiscal policy started to loosen again and the outburst of the global financial crisis caused the government to implement some fiscal stimulus measures, worsening the situation further. (IMF, 2013). In 2010, fiscal consolidation started again and consisted primarily of revenue measures like increase in

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

value added tax and excise taxes and some cuts in benefit entitlements (ECB, 2010). At the end of the sample the public debt amounted however to 46% of GDP and was 30 per cent of GDP higher than in 2000.

Poland was also among countries which were running large fiscal deficits in 2000s. This policy led to significant increase in debt to GDP ratio. Several step, including tax reform, were taken in order to improve the government balance. The fiscal consolidation has been quite successful, since the budget deficit was decreasing for several years and in 2007 the public debt decreased for the first time since 2004. However, economic slowdown resulting from financial crisis and lower income tax revenues caused the public finance situation to worsen again and the budget deficit amounted to 7,9 percent of GDP in 2009. Further consolidation measures were implemented, including tightened eligibility for early retirement, a ceiling of CPI+1 o the growth of discretionary expenditures and VAT and excise taxes increase. As a result, the deficit decreased, however remained still quite high and the debt to GDP increased further. Recent changes in the pension system (transfer of funds from the pension second pillar to the general government) will improve public finance statistics but they will cause only a one-time reduction in the level of debt and the effect of this reform goes beyond the time frames of the study.

Data and results

To overcome to some extent the difficulties coming from very short samples for the analyzed countries, we use quarterly data on government finance coming from the Eurostat database.³ The primary balance is the general government budget balance excluding the general government interest payments and is expressed in percent of GDP. The debt stock is the general government consolidated gross debt in percent of GDP. The data have been seasonally adjusted. The sample period begins in Q1 2000 and ends in Q3 2013.

In the first step of our analysis we test for the stationarity of the first difference of the government debt. As described above, for the robustness purposes we conduct Augmented Dickey-Fuller test, Phillips-Perron test and the Ng-Perron test. As the sample period includes the financial crisis, which created challenge for fiscal policy, we conduct also unit root tests allowing for structural breaks in the series – Zivot-Andrews test and Perron (1997) test. The tests results summarizes Table 1. The results suggest that

³ Although to the analysis of fiscal policy yearly data would be obviously preferred, short time-series for transition economies would unable such analysis. However, it is not unusual to use quarterly fiscal data in empirical studies (see for example Baldi and Staehr (2013), Haug et al. (2013), Franta (2012)).

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

in all three countries the null of a unit root should be rejected, so it leads to the conclusion that this condition for fiscal solvency is satisfied. The break-type test report breaks in the series in the second half of 2008 or the beginning of 2009.

In order to verify the relationship between primary surplus and the debt stock, first one has to check the order of integration of the analyzed series. The same order of integration would allow for testing for cointegration between the primary surplus and lagged level of public debt. The results of the unit root tests for these two variables are presented in Table 2.

The results of the standard unit root tests suggests the rejection of the null in the case of the Czech Republic and Hungary. In the case of Poland only the ADF test leads to the rejection of the unit root hypothesis, while Phillips-Perron and the Ng and Perron tests suggest that primary balance in Poland is a unit root process. The test allowing for the structural break in the series confirm the unit root in the case of Poland and add the Czech Republic to the countries where primary balance is non-stationary.

For those countries, where the public debt and the primary balance proved to be I(1) process (i.e. the Czech Republic and Poland), we analyze cointegrating relationship between those two variables, as suggested by Bohn (2007). As we use quarterly data, we check the relationship between primary surplus and the debt lagged by 4 periods. Table 3. presents results for the Johansen cointegration test.

**Proceedings of the 8th International Conference on Applied Economics

	At most 1	3.13	9.16	3.13	9.16

Source: Own calculations.

The results of the test indicate one cointegrating relationship between primary surplus and lagged debt in the case of the Czech Republic (at the 5% level), but no cointegration in the case of Poland. This would suggest that the public finances in Poland were not sustainable. However, as the previous test suggested structural breaks in the series, there may also be structural break in the cointegrating relationship. We test for the possibility using Gregory and Hansen test. We use the model with level shift and trend. The results of the test are presented in Table 4.

Table 4. Gregory-Hansen test for structural shift in cointegrating relationship

	ADF test		Phillips test	
	ADF* stat	Break date	Z _a * stat	Break date

Poland	-4.04	2009Q4	-12.44	2008Q3

Source: Own calculations. ** denotes significance at the 5% level. Critical values from the Gregory and Hansen (1996).

The Gregory and Hansen test confirms the results of Johansen cointegration test, since we reject the null of no cointegration for the Czech Republic, while we cannot reject the null in the case of Poland. Therefore we conclude that in the case of Poland there is no evidence of existence of the relationship between the primary surplus and lagged levels of the public debt. No such relationship suggests the prevalence of fiscal dominance regime in Poland in the analyzed period.

The last step of the analysis is the estimation of the parameter β in the cointegrating relationship in the equation [5]. The parameter is estimated using the DOLS. Positive and statistically significant β would indicate prevalence of the monetary dominance regime and sustainability of the fiscal policy, while negative β or not statistically different from zero would

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

indicate the regime of fiscal dominance. The analysis is performed for the Czech Republic, as for the country the cointegrating relationship between primary surplus and lagged debt was found, as well as for Poland to confirm the previous results of no cointegration. The estimated equation contains (beside lagged values of the debt) dummy for the year 2008, as for the most series in 2008 break in the data was indicated. In the case of the Czech Republic the equation contains also a dummy for the fourth quarter of 2001. The estimation results are presented in Table 5. In both countries the estimated parameters prove to be negative and statistically significant indicating no sustainability of public finances.

Table 5. Estimation of parameter β in cointegrating relationship between primary balance and debt

Source: Own calculations. *, **, *** denote significance at the 10%, 5% and 1% level respectively. Standard error in parentheses.

For Hungary, where the tests reported structural breaks in the series but no unit root process, the relationship between primary surplus and lagged debt stock is estimated using least squares with breaks. Estimated parameter is positive and statistically significant (Table 6.).

Table 6. Estimation results of relationship between primary balance and debt for Hungary

However, as already described) positive values of β may occur under MD as well as under FD regime. In order to verify if the regime in Hungary was monetary dominant or fiscal dominant, Granger causality test is performed. Somewhat surprisingly, the results (presented in Table 7.) indicate,

that the causality runs from the public debt to primary surplus, suggesting the prevalence of monetary dominant regime in Hungary.

Table 7. Granger causality test

Conclusions

In this study we tested the sustainability of fiscal policy and the existence of monetary versus fiscal dominance in three central and eastern European economies: the Czech Republic, Hungary and Poland. The empirical methodology was based on analysis of long-run relationship between primary balance and lagged public debt (the so called backward-looking approach). Existence of positive, statistically significant relationship indicates the MD regime.

The results obtained suggest that over the analyzed period in the Czech Republic and Poland prevailed FD regime, while in Hungary – MD regime. These results may seem surprising taking into account, that Hungary is heavily indebted country, while the Czech Republic belongs to group of countries with relatively low debt to GDP ratio. However, although in the Czech Republic the public debt is relatively small, it was rising significantly over the analyzed period despite fiscal consolidation and therefore results indicate, that this policy is not sustainable in the long term. Similar situation occurred in Poland – fiscal consolidation measures aimed at reducing debt proved to be not enough to prevent debt from rising in the face of adverse developments after beginning of the global financial crisis. On the other hand, in Hungary a one-time reduction in debt caused by changes in pension system improved fiscal situation and primary surpluses generated since then helped to stabilize debt. Further fiscal consolidation measures applied in the Czech Republic and Poland may also change the conclusions about fiscal sustainability over next years, so this could be a field for future research.

**The Impact of Selected Variables on the VAT
Gap in the Member States of the European
Union***

JEL Classification: *H26; H32*

Keywords: *tax gap; value added tax; Corruption Perception Index; GDP growth; VTTL model; regression*

Abstract: One of the most serious problems of fiscal character is the issue of the tax gap. The tax gap is defined as the amount of tax liability faced by taxpayers that is not paid on time. The tax gap comes from three main areas of non-compliance with the tax law – firstly from underreporting of income, secondly from underpayment of taxes and thirdly from non-filing of returns. The tax evasions in the area of value added tax form one of the largest groups of tax gap. This article describes the current situation in the field of tax gap in selected countries of the European Union, namely the VAT gap. The aim of this paper is to determine a dependence of the VAT gap on three variables, the Corruption Perception Index CPI, GDP growth rate and the basic VAT rate. A method of the regression analysis has been used, performed on data in the years 2000-2011. In spite of the fact that it could be assumed that tax burden will affect the VAT gap the most, the highest dependence was shown in the case of the Corruption Perception Index.

* This paper was supported by the Ministry of Education, Youth and Sports of the Czech Republic within the Institutional Support for Long-term Development of a Research Organization in 2015.

Introduction

Taxes began to be paid in ancient times, and since that time there is a problem called a tax gap. It is in fact a tax avoidance which creates a tax gap between what should be paid in taxes and what has really been paid. Tax authorities, not only in the European Union, are currently facing major challenges in this regard in achieving the goals that would reduce this gap.

The problem of the tax gap is considerable in the European Union countries (but stable as Ángeles Castro & Ramírez Camarillo, 2014 in the case of OECD countries in period 2001-2011 claims). Potential returns that do not end at tax collectors of individual tax administrations amount to one trillion Euros per year (in the US 345 billion dollars, according to IRS data). Significant amounts of money currently end up in tax havens, which is a major obstacle in the period when most European countries have their budgets in deficit. That is the reason why the economic statistics focus on calculation of a tax gap. In this approach, it is important to quantify the theoretical amount of tax, from which the tax gap is established.

For the purposes of analysis in this article the VAT gap has been chosen, as it is the most important part of the tax gap. The VAT gap is calculated as the difference between the theoretical VAT liability ascertained from the national accounts and the VAT revenues accrued by the financial authorities (Zidkova, 2014, p. 514).

A motivation for writing this article was to determine whether a generally accepted view of the positive relationship of the tax burden and tax gap of that tax type actually exists and whether it is statistically significant. For the comparison two other indicators namely the Corruption Perception Index and GDP growth rate have been selected.

The paper concerns three parts - theoretical, methodological, and research. The first part describes the theoretical approaches and ways of measuring the tax gap and the VAT gap through fiscal sustainability and VTTL model. The second part describes the methodology of research, where the method of regression analysis has been chosen for determining the VAT gap, depending on three variables – Corruption Perception Index, GDP growth rate and the basic VAT rate. When examining the dependence, the data from 2001 to 2011 were used. The third part is devoted to the VAT gap in selected countries of the European Union and the application of the regression model for the member countries.

Theoretical Approach to the Tax Gap and VAT Gap

Her Majesty's Revenue and Customs defines the tax gap as the difference between the selected taxes and tax, which should be selected, so the theoretical liability (HMRC, 2013). Theoretical liability is a tax that would be paid if all people and companies respected the tax law (Tyrie, 2012). Armstrong, Bloin & Larcker (2011, p. 395) defined the concept of the book-tax-gap as spread between aggregate financial statement income and aggregate taxable income.

According to Plumley (2005) or Warren & McManus (2007) there are three components of tax gap – non-lodgement (non-filing), under-reporting and under-payment. Hurst, Li & Pugsley (2014, p. 19) indicated that the self-employed systematically underreport their income in U.S. and individual income represented over half of uncollected revenue (Branham, 2009, p.1507).

Tax gap also covers evasion of participants in legal activities in the informal economy; it means that part of the economic activity that does not pass through official economic statistics (more about hidden – illegal – economy see Giles, 1999). These participants are informal contractors, domestic workers and street vendors who do not report their income and do not pay taxes. On the other hand, the tax gap does not include unpaid taxes from people who work in the informal economy, which consists of illegal activities such as drug trafficking, illegal gambling and prostitution (Todler, 2013).

A typical feature of the tax gap is financial flows, which can be divided into two categories – (legal) avoidance and (illegal) evasion (Gemmel & Hasseldine, 2014, p. 275). The first one is the legal avoidance, which is inappropriate or irregular, because it is not permitted under rules and customs. It includes the avoidance of tax liabilities. To define tax avoidance is more difficult than to define the tax evasion, because in this case there is no legal basis. Tax evasion is characterized as an effort to minimize tax assessment without deliberate deception (which would be considered as tax evasion), but in contrary to the law. Therefore it is an abuse of gaps and deficiencies in the tax system and other legislation in a way that has not been foreseen by the law.

The other category includes unlawful flows. Concerning the tax evasion it means minimizing taxes. Tax evasion may be either legal or illegal. Legal tax evasion is a condition where the taxpayer uses the shortcomings in the law in a way that was not intended by the legislature. Illegal tax evasion is

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

the case when the taxpayer receives a tax benefit in contrary to the law, ie by its violations. These tax evasions usually arise from a false tax statements denying taxes to tax authorities or stating false requirements for tax deductions.

The issue of tax evasion has been dealt with many scientific publications, for example Chiarini, Marzano & Schneider (2013) quantified the elasticity between tax evasion and average tax rate in Italy in the period 1980-2006, as well as Levaggi & Menoncin (2013). According to Di Lorenzo (2014) a lower tax rate on labour income enabling money to flow from households to companies through private consumption reduces incentives for tax evasion. Gillman & Kejak (2014) claimed that upward trend in good and human capital sectors gradually decreases tax evasion.

The tax gap is one of the most commonly used indicators of fiscal sustainability. The construction of this indicator is based on the same approach, firstly the level of sustainable fiscal variables is calculated, and then the gap is defined as the difference between sustainability and the current level of the primary deficit or tax rate. Sustainable level of fiscal variables ensures the convergence of the debt ratio to a final value and its calculation is governed by the terms of sustainability:

$$\lim_{T \rightarrow \infty} \left[\sum_{t=1}^T pd_t \left(\frac{1+r}{1+y} \right)^{-t} \right] = -b_0 \quad (1)$$

where pd is primary deficit, r is the interest rate, y represents the real GDP growth rate and b_0 is the initial debt ratio.

This condition says that the present discounted value of future primary surpluses should be equal to the initial value of the debt. Then the primary deficit may be expressed as:

$$pd^* = -b_0 \frac{r-y}{1+y} \quad \text{or with omission } (1+y): \quad pd^* = -b_0(r-y) \quad (2)$$

Calculation of the primary gap is then expressed by the following equation:

$$pd^* - pd_t = -b_t(r - y) - pd_t \quad (3)$$

b_t represents ratio of debt to GDP.

In the calculation of the primary gap is thus necessary to know the current primary deficit and debt, and it is necessary to draw assumptions of expected long-term average values of interest rates and the rate of real GDP growth. If the current primary deficit is higher than sustainable ($pd^* - pd_t < 0$), the ratio of debt to GDP will increase without any constraints and fiscal policy can be called unsustainable. Sustainable primary deficit can also be used as the target of government towards sustainable deficit. This is an attractive factor, since fiscal balance is usually the ultimate object of the interests of creators of economic policies. The primary difference is a scale of the adjustments that need to be returned to the level of fiscal balance and sustainable level. The primary deficit can be expressed as the difference between expenditures and revenues:

$$pd_t = g_t + h_t - \tau_t \quad (4)$$

where g is a consumption (including investment), h are the transfers and τ represents a current tax rate. All variables are measured as a share of GDP. It is important to calculate the sustainable level of the tax ratio:

$$\tau^* = \frac{r - y}{1 + y} \cdot \left\{ \sum_{t=1}^{\infty} \left[(g_t + h_t) \cdot \left(\frac{1+r}{1+y} \right)^{-t} \right] + b_0 \right\} \quad (5)$$

By subtracting the current tax rate from sustainable levels we get a so called indicator of the tax gap:

$$tax_gap = \tau^* - \tau \quad (6)$$

If sustainable tax ratio (τ^*) is greater than the current tax rate (τ), which means that the tax gap is positive, fiscal policy will be necessary to be ad-

justed to prevent excessive accumulation of debt. The tax gap indicator should not lead to the conclusion that the best way to correct the current policy is to raise taxes. For example Alvaiez-Martinez & Polo (2014) indicated the enormous difficulties of the government of Spain faces to close the deficit gap by raising taxes, Gemmel & Hasseldine (2012) claimed that an extra dollar in tax revenue not always reduce the tax gap by a dollar. This indicator only indicates that the current tax rate is not high enough to finance future spending and debt.

The estimation of the VAT gap can be done through the model VTTL. The Vat Total Theoretical Liability (VTTL) as a model, and VAT gap derived from VTTL are general indicators. The basic objective of measurement is to determine the overall level of the VAT gap comparing the pure theoretical tax with real revenues from the VAT. This difference is called the VAT gap. By subtracting net VAT revenues and net VTTL the VAT gap arises:

$$G_{VAT} = NR_{VAT} - VTTL_N \quad (8)$$

where G_{VAT} represents VAT gap, NR_{VAT} is the net revenue from VAT and $VTTL_N$ is the net VAT total theoretical liability. The percentage difference is further calculated by dividing the VAT gap and net VTTL:

$$D = \frac{G_{VAT}}{VTTL_N} \quad (9)$$

where %D is the percentage difference.

Methodology of the research

The aim of this paper is to determine the dependence of VAT gap on three variables; the regression analysis was performed on data from the years 2000-2011, from which the arithmetic mean was calculated. To implement the regression analysis, three independent variables explaining one dependent variable were selected. The dependent variable in the model is VAT gap, expressed as a percentage of the VTTL. The values of VAT gap for individual member states were taken from the study of CASE (2012). The exception is Cyprus, which was excluded from the analysis due to the revision of the national accounts. Three indicators as independent variables

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

were selected, namely Corruption Perception Index, GDP growth rate and the basic VAT rate.

The Corruption Perceptions Index (CPI) represents the area of socio-institutional factors. Its main task is to sort countries according to how corruption is perceived in the public sector. Each country indicates the perceived level of public sector corruption on a scale of 0 to 10, where 0 means that a country is perceived as very corrupt, while 10 means that it is uncorrupt. This index is compiled annually by Transparency International in order to control factors relating to corruption in the public sector, which can directly affect the tax compliance of taxpayers. According Liu & Feng (2015, p. 57) countries with more complex tax system tend to be more corrupted than countries with less complex tax system. In the case of the CPI (according to CASE, 2012) the expected impact is negative, which means that the increasing value of corruption index (positive perception of corruption) decreases tax evasions. Regarding the results of this index within the European Union, the Nordic countries reach the highest values in average of twelve years. Finland reached the value of approximately 9.51, followed by Denmark with the average value of 9.46 and Sweden with the mean value of 9.24. Conversely, the lowest measured value was reached by Romania with the average value of 3.23, Bulgaria with the value of about 3.82 and Latvia, which reaches the average value of 4.17.

Other selected variable is GDP growth rate which has been chosen as an indicator in the area of economic determinants. The calculation of the annual growth rate of GDP volume allows comparing the economic development dynamics both over time and among economies. For measuring the growth rate of GDP current prices recorded at prices of the previous year were used and thus calculated volume changes are kept in the values of the reference year. The used data were taken from the Eurostat statistics and then averaged over twelve years. The study of CASE (2012) expected a negative impact in this field, too, which means that the increase in economic growth reduces the VAT gap. Estonia reaches the greatest economic growth in average of the EU countries with the average growth of 4.76%, followed by Lithuania with the increase of 4.66% and Slovakia with the value of the average growth of 4.43%. As regards the countries with the lowest GDP growth rate, the worst results were achieved by Italy with the average of 0.67%, Portugal with the average growth of 0.8% and Denmark with the value growth rate of 0.9%.

The basic VAT rate has been chosen as the last independent variable representing tax factors. Regarding the expected impact, the study of Reck-

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

on (2009) assumes a positive impact on the VAT gap, which means that if the basic VAT rate increases, the tax evasion grows. The basic VAT rate in the European Union member states in the monitored period ranges from 15% in Luxembourg to 23.7% in Hungary. The statistics of the four selected indicators are specifically listed in Table 1.

Table 11. The basic characteristics of regression analysis in the selected EU-Members in the years 2000-2011

Member state	CPI	GDP growth	Basic VAT rate	VAT gap, % of VTTL

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

Regression analysis is carried out using a method of least squares. This method has several assumptions. Firstly, spatial correlation was determined by using the Pearson correlation coefficient, further constancy variance was tested using graphical methods and based on ARCH test and finally assumption of normality was assessed using the test model Jacque-Bera (Cipro, 2008). These assumptions were tested in program EViews.

The basic equation for expressing simple linear function is the following equation.

$$y = \beta_0 + \beta_1 x + \varepsilon \quad (10)$$

where β_0 and β_1 are the values of the parameters of the regression line, ε is a random component. These values obtained estimates b_0 and b_1 , which are called the regression coefficients, and can be calculated using the least squares method. Formulas for the calculation have a following form:

$$b_1 = \frac{\overline{xy} - \bar{x} \cdot \bar{y}}{\overline{x^2} - \bar{x}^2} \quad \text{and} \quad b_0 = \bar{y} - b_1 \bar{x} \quad (11)$$

Regarding the statistical significance of the model as a whole, it is necessary to establish a zero (H_0) and alternative (H_1) hypothesis and then test these hypotheses at the significance level $\alpha = 0.05$.

H_0 : The linear regression model is statistically insignificant.

H_1 : The linear regression model is statistically significant.

Another important requirement is to perform T-test, which examines each parameter β_0 and β_1 separately, if they are not equal to zero. Even in this case null and alternative hypotheses are determined and tested at a significance level $\alpha = 0.05$

H_0 : Parameters β_0 a β_1 are equal to zero.

H_1 : Parameters β_0 a β_1 are not equal to zero.

The VAT Gap in selected EU countries and the application of the regression model

The VAT rates differ in the EU Member States, causing that tax evaders are looking to profit from the gaps and incompatibilities between different national tax systems (Sharman, 2012, p. 17).

Estimated VAT gaps have a very wide dispersion among countries, ranging from 21 million Euros in Malta, to 36,134 million Euros in Italy (in 2011). Across the European Union is the average VAT gap in 2011 (20%) expressed as a percentage of the VAT total tax liability. The estimated total amount of the VAT gap of EU-26 is approximately 193 billion Euros, or expressed as a percentage of GDP EU-26 in 2.1%. Data are shown in Table 2.

Table 12. Estimating the VAT gap in the EU Member States in 2011

Member state	VTTL 2011 (v bill. Eur)	VAT gap (in mil. Eur)	VAT gap as % of VTTL	VAT gap as % of GDP

Source: own according CASE (2012)

To perform regression analysis, three independent variables have been selected, that explain one dependent variable. The dependent variable in the model is VAT gap, expressed as a percentage of VTTL. The Corruption Perception Index reached the highest significance from three selected explanatory variables. Figure 1 below shows the dependence of the VAT gap and CPI.

Figure 1. Dependence of VAT gap and Corruption Perception Index

Source: own calculation

Figure 1 shows that there is a relation between the VAT gap and Corruption Perception Index in this case. Equation of line of regression analysis has thus the form:

$$y = -3.669x + 40.157 \quad (12)$$

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

From the equation of line of the regression analysis it is evident that in this case the negative relationship of examined variables is confirmed, therefore, when the value of CPI raises, the tax evasion decreases.

Some countries deviate from the established regression dependence, Romania is one of these countries. If we focus on the individual average values of Romania in both indicators in the years 2000-2011, as regards VAT gap, Romania reached the highest value, namely 41.9%, and on the contrary in the case of Corruption Perceptions Index it has the lowest value, in average 3.225. This is the highest level of corruption in examined countries of the European Union. Lithuania is another deviating state is. With the indicator of the VAT gap (in terms of size of this indicator) it ranks in the second place behind Romania with the average of 34.6%. Lithuania is reaching the value 4.72 of the Corruption Perceptions Index and it belongs to the countries of the European Union with a very low level of its value, which shows a high level of corruption in this country. Sweden achieves the best results, as it has a low rate of the VAT gap and a high level of the CPI, which indicates a confidence in the field of corruption politics. According to the average values of Sweden from 2000 to 2011, the VAT gap stands at 4% and the corruption perception index is the third highest among European Union countries, with an average value of 9.2, just behind Finland and Denmark. The following table 3 shows the concrete results of the regression analysis.

Table 13. Output of regression analysis exploring the dependence of VAT gap and Corruption Perceptions Index

Source: own calculation.

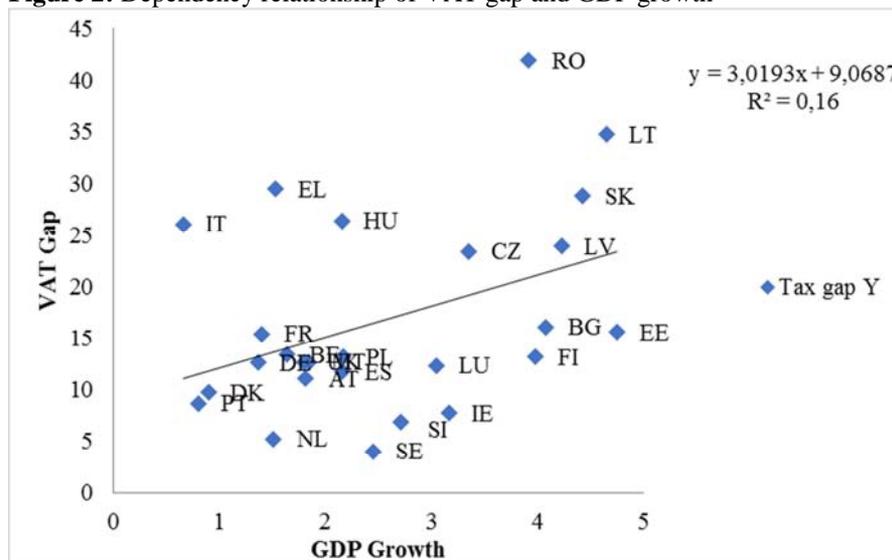

In this model, the probability value (significance F) is less than the tested significance level of 0.05, which means that the null hypothesis is rejected, and the regression model is statistically significant.

The value of correlation coefficient, which is shown in Figure as multiple R indicates the strength of dependence of selected variables. Specifically, it means that the VAT gap is approximately 75% dependent on changing of the Corruption Perceptions Index. Another value shown in the table is the value of reliability R – it is also a coefficient of determination. It indicates how much of the total variance of the dependent variable, i.e. VAT gap, is explained by the regression model. In this case it is about 56.1%.

The level of significance is compared with the value P in the table above. Thus, if P value is lower than the level of significance, as in this case ($2.83818E-09 < 0.05$), we reject null hypothesis and so the alternative hypothesis is valid, therefore, both parameters are not equal to zero.

The second examined variable is GDP growth and its impact on the emergence of VAT gap. In this case a very little dependence has been found, which is shown in Figure 2 below.

Figure 2: Dependency relationship of VAT gap and GDP growth

18-19 June 2015, Economics and Finance**

Equation of line of regression analysis has thus the form:

$$y = 3.0193x + 9.0687 \quad (13)$$

There are many more countries that deviate from the established linear line in the case of the growth rate. It is Romania, which has the highest level of the VAT gap from all the EU countries, as mentioned above, and regarding GDP growth, Romania ranks among the countries of the European Union which have high GDP growth rate in average in twelve years, about 3.9%. Slovakia is another deviating country. As regards the size of the VAT gap, Slovakia ranks among the countries with the high level of gap and reaches the average value of approximately 28.8%. The GDP growth rate of Slovakia reaches high values that are the third highest among the EU countries, behind Estonia and Lithuania, with an average of approximately 4.4%. The lowest point is the result of Sweden due to its lowest rate of the VAT gap and its GDP growth rate with the average value of approximately 2.4%.

Table 4 shows the results of the regression analyzes exploring the dependence of VAT gap and GDP growth.

Pearson's correlation coefficient is approximately 40% of the value in this case, ie the dependence is much smaller than in the previous case. VAT

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

gap is therefore 40% dependent on GDP growth, which is very low. The coefficient of determination shows that with the help of the regression analysis only 16% of VAT gap is explained.

By testing the statistical significance of the regression model, similarly to the previous case at a significance level $\alpha = 0.05$, the calculated probability shown in the figure is lower than the significance level α ($0.042878191 < 0.05$). The null hypothesis is again rejected and the linear regression model is statistically significant.

Furthermore, the tested value P is lower than the significance level α ($0.033595657 < 0.05$). The null hypothesis is rejected and it is valid that the test parameters are equal to zero.

However, it does not confirm the expected effect which the GDP growth should have on the VAT gap. According to the regression the expected negative impact that the VAT gap falls with the increase of the GDP growth is not valid.

The last monitored variable is the basic VAT rate and its impact on the VAT gap. Regarding this variable, the dependence is negligible, almost zero, which implies that the amount of the basic VAT rate has no effect on the size of the VAT gap. Table 5 shows the results of regression analysis, from which it is seen that the model as a whole is not statistically significant.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

The correlation coefficient regarding the dependence of the VAT gap and the basic VAT rate reaches the value of just 6.3%. It indicates there is no relation between these two variables and they are not mutually affected. The determination coefficient, which indicates what proportion of the total variance of the dependent variable is explained by the regression model, reaches only 0.4%. It means that this model is not explained by the selected dependent variable.

The calculated probability, which is shown as the significance F in the table, reaches a higher value than the specified level of significance level α ($0.757922588 > 0.05$). It confirms the null hypothesis, and this model is statistically insignificant and thus could not demonstrate any anticipated impact.

Conclusions

Currently, one of the biggest problems in the fiscal area is called the tax gap. A failure of taxpayers to pay taxes creates important arrears that are subsequently missing in the budgets of individual states, which is in the period when most of the member countries of the European Union are in deficit, a major problem that needs to be solved. The tax gap arises in two ways, partly caused by tax evasion, partly by tax avoidance. The main cause is primarily omission of the tax laws by tax payers.

The European Union belongs to the areas with high tax burden. The overall tax ratio reaches 38.8% as regards the European Union. In comparison with the OECD countries, there are only two countries that exceed the 30% limit, which is Canada and New Zealand. Regarding the European Union member countries there are striking differences in the level of taxation as well - the overall tax ratio varies from 26% in Lithuania to 47.7% in Denmark.

In the article the influence of the dependence of the VAT gap and three selected independent variables, namely the corruption perception index, GDP growth rate and the basic VAT rate, were examined. Of these three variables the Corruption Perceptions Index demonstrated the highest dependence regarding the first mentioned. 75% dependence of the VAT gap on the Corruption Perceptions Index was demonstrated. According to the tests, the model was determined to be statistically significant. Regarding the GDP growth rate, the model is evaluated as statistically significant and the variable dependence is approximately 40%. Concerning the basic VAT

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

rate there has been no evidence of dependency and the model is insignificant as a whole.

In 2012 the European Commission published an action plan in the engagement against tax evasion in the European Union that proposes options for reducing and preventing tax evasion. Within the action plan, the Commission proposes several measures to reduce the tax gap, including the establishing of the Forum of the VAT. It is a dialogue between the representatives of large, medium and small enterprises and tax authorities, who can exchange their views on functioning of the VAT in the European Union. Another possibility is the introduction of a rapid response mechanism against the VAT fraud, which would allow the Commission to react very quickly to the VAT fraud and allow a Member State to deviate from the standard measures. In the following years the Taxpayer Identification Number – TIN should be implemented, as the optimal means to identify taxpayers.

But as Hamemi (2014) claims the collaboration between policymakers and citizens would be the best solution and the most effective for reducing the tax gap.

Abstract: The purpose of this article is an attempt to determine the scope of Polish companies operating on the market, which could raise capital by the means of the Warsaw Stock Exchange. Therefore, a preliminary analysis is made of selected results achieved by economic entities in the years 2003-2012 as well as values and trends produced by them, with particular emphasis on the fluctuation of their number, undertaken investments, structure of revenues and expenses and financial performance, against other countries of the European Union. To illustrate the whole potential volume, the study covered all structures operating in the market: micro, small, medium and large enterprises and their results are shown on the basis of statements arising from the undeniable specificity of the entire SME sector and large companies operating in Poland.

Introduction

Since Poland's entrance to the European Union was eleven years ago, it may seem that Polish legislators have made great strides in enacting changes related to capital ownership. However, small and medium-sized enter-

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

prises that produce nearly 50% of Polish GDP and form two-thirds of the Polish labour market still encounter limitations in their ability to raise capital for development (Duliniec, 2011, pp. 412-420). The gross value produced by the SME sector in 2012 is exactly 48.5% of which 29.7% was produced by micro-enterprises, 7.8% by small, 11.0% by medium-sized enterprises and 24.5% by large. According to data from the European Commission (SBA Fact Sheet, 2014), the structure of Polish enterprises more and more resembles that of the EU, systematically increasing the service sector (29.7% in 2012), and decreasing the trade and industrial sector (respectively in 2012: 25.8% and 29.6%)¹. Still, when compared with the EU, it is indeed dominated by micro-enterprises, while small companies' contribution is about half of that. Micro, small and medium-sized enterprises provide the Polish economy with the structural changes and framework for socio-economic development, at the same contributing to the global economy (Bass, 2006, pp.10-11) and affect the basic macroeconomic indicators (see: Grzywacz, 2012; Jaworski, 2010). While providing innovative potential, at the same time they are still subject to the so-called loan discrimination phenomenon and it is much harder for them than for large companies to acquire a bank loan (see: Bielawska, 2001; Duliniec, 2011; Łuczka, (2001, 2013); Łukasik 2010). Among other things, this is a reason why the most popular form of funding is from own finances, and only later do owners turn to loans and leases (Wasilewska 2007, p.454; 2006, pp.539-545). So why do so few companies look for financing through the stock exchange? The question arises of how they understand the cost of capital and the investment decisions regarding development? The qualitative characteristics of SMEs often give them an advantage over large companies, especially when it comes to the speed of adjusting to the market or bringing about change, but in some circumstances significantly discriminate against them, highlighting the existing barriers to development and expansion (Łuczka, 2007, pp.29-49; Daszkiewicz, 2004, p.61). Nevertheless, in a macroeconomic sense, the SME sector sets a trend of economic development, especially through the changes that occur in the local and regional markets (Bera, 2010, p.338; Strużyński, 2004, p.19).

In literature on the subject, and in the EU, companies are classified according to their size (Łuczka, 2013, p. 125; Cassar & Holmes, 2003,

¹ According to Eurostat data for 2010 in Poland there are definitely more trade enterprises (35.5%, 28.6% in the EU) and much less service enterprises (36.3%, 45.9% in the EU). Results for industry oscillate between 2.1% (Poland 12.5%, 10.4% in the EU). Construction is at a similar level (Poland 15.8%, EU 15.2%).

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

pp.123-147; Gregory et al., 2005, pp.382-392; Art. 104-106, DZ.U. 2004 Nr 173 poz. 1807, p.54; Załącznik nr 1 Rozporządzenia Komisji (WE) Nr 364/2004, DZ.U. L 124 z 20.05.2003, p.36). The Central Statistical Office (CSO) classification used for the purposes of this article takes into account the employment criterion and ignores the values of revenues and assets. Micro-enterprises were singled out in each of the presented statistics for both readability and clarity of the results achieved by small companies operating in Poland, but also because of the currently noticeable activity and dynamism that occurs in the development of programs directed primarily to small and medium-sized enterprises and to people who are self-employed, who focus their business around innovation and modern trades in the industrial and service sectors, so-called start-ups (see: Blair & Marcum, 2015, pp.249-265; Cassar, 2004, pp.261-283; Fourati & Affes, 2013, pp.244-254).

After the mass privatization process which took place in Poland from 1990, the stock exchange first directed its actions towards large companies and is now increasingly beginning to attract new issuers among companies belonging to the SME sector. The Warsaw Stock Exchange (WSE) cooperates with the Ministry of Finance to create a system of incentives that would enable and support innovative and dynamic companies operating from this segment. Thus far they mainly supported the innovative economy, a sector that is far less likely to be financed by the banks (New Connect) (see: Kołosowska, 2013; Kordela 2013). And yet the stock market, which is the most important institution of the capital market, is not only a valid source of financing of companies, but also aids the transformation of small businesses into medium and large enterprises (Wasilewska & Jankowska, 2005, p.36), thus it would best fulfil its mission by supporting the financing of private Polish companies (Jaworska at al., 2013, pp.249-265). In order to do this it seems to be necessary to create a whole system of activities that encourage the use of such sources of funding, not only for entrepreneurs seeking the development of their own companies, but also for future investors. The concept of the stock exchange should be better understood and the existing tools described in a more accessible way so as to encourage Polish entrepreneurs to restructure their own companies, to introduce corporate governance and transparent accounting and the use of analytical indicators in the current management of the company (Bień, 2008, pp. 98-127). There would be a significant diversification of the role of banks as a source of capital for development, and a part of the capital accumulated would be transferred to the capital market, including the stock exchange, which

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

would significantly affect the development of the economy. Worth mentioning is the work currently being done by the WSE along with the Polish Agency for Enterprise Development (PARP), on developing projects with funding from the EU in the years 2014-2020 to support the SME sector, including micro-entrepreneurs, wishing to debut on the WSE, as well as young people, planning to establish an innovative business (PAP, 2014). The money will come from the Operational Programme "Intelligent Development" and will gather experts who can help claimants evaluate their chances and help prepare the appropriate documentation. The goal is activating companies in the SME sector, which currently insufficiently use external sources to finance their investment through capital markets (PAP, 2014). This program is designed to be the successor of the Innovative Economy Operational Programme, which operated in 2007-2013 and the budget is to reach more than EUR 8.6 billion, of which research and development projects carried out by companies and scientific and industrial consortia, are expected to receive approx. EUR 3.45 billion, while innovative initiatives in companies will receive approx. EUR 2.63 billion. According to data obtained from PARP on 12 February 2015, information regarding the program has already been established with the European Commission. This joint initiative of PARP and the WSE, serving the popularization of the stock exchange, seems the more important for the Polish economy, the more opinions are published that there is an insufficient number of IPOs successfully debuting on the WSE after the Treasury stopped introducing large companies to the exchange (Tychmanowicz, 2015). The belief is that this bad streak, which affects the IPO market, is not a matter of economic crisis, but only a lack of interest from sufficiently large and structured companies (Adamczyk, 2014).

It should be noted that the entry of the company on the WSE is determined by its legal form. According to Polish legislation, this status can be claimed only by joint-stock companies and limited joint-stock partnerships whose conditions for admission are regulated by the Stock Exchange regulation and the regulation of the Council of Ministers from 14 October 2005, on determining the conditions that must be met by official listings on the stock market and by issuers of securities admitted to trading on the market (see: DZ.U. nr 206, poz.1712). According to the classification of the CSO these companies are recognized as legal persons. With the objective of proper verification of data, the analysis conducted and presented in the article, was constructed on the basis of a division of business entities, which is in accordance with the classification of the CSO. It includes legal

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

persons, entities without legal personality and natural persons who were carrying on business in Poland in the years 2003-2012, where a collection of natural persons is understood as natural persons as well as persons who work in companies formed on the basis of a contract made based on the Civil Code (private partnerships), and a group of entities who have legal personality (legal persons) is presented together with the organizational entities without legal personality (CSO, 2012). In order to determine the scope of companies that can seek to acquire sources of financing through the stock exchange, the study has included all stakeholders, detailing among them the legal persons, and examining their number and market share as well as their financial condition, each time taking into account Poland's place in macroeconomic terms obtained from various indicators against the current performance of countries of the European Union.

Methodology of the research

The study involved 10 years of Polish entrepreneurship, trying to distinguish in the most precise way those business entities which could apply for the status of a listed company in Poland. Joint stock companies and limited joint-stock partnerships were classified as legal persons, along with other commercial companies². This collection has been analysed in individual

² In Poland commercial companies include:

- commercial partnerships and capital companies with a legal personality (joint-stock companies and limited liability companies)
- partnerships without a legal personality only with legal capacity (professional partnerships, general partnerships (unlimited), limited partnerships, and limited joint-stock companies).
- These figures do not include companies classified according to the Polish Classification of Activities 2007 section A, K and O, that is, according to the Polish division:
- companies of the administrative law (water companies and the common land)
- pan-European companies (European companies and European economic grouping investors)
- self-government organizations and foundations
- universities
- autonomic public health centers
- units from chapter 94 PKD 2007.

The division is made on the basis of legal form (1, 2, 9). Units that are natural persons engaged in economic activities (Code 9) CSO assigns to natural persons. Entities that are legal persons (code 1) are allocated to legal persons. Organizational units without legal personality (code 2) also to legal persons. Specific legal forms, which are included in the personal scope of the publication of CSO codes are: 15, 16, 17, 18, 19, 20, 21, 23, 24, 40, 79, 99..

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

obtained economic indicators and then depicted as compared to other businesses and the results of the EU, with a particular emphasis on entities belonging to the SME sector. For clarity and precision, always from the small enterprises sector highlighted were micro-enterprises³.

For the purposes of calculation and tabular or graphical presentation of the obtained results, mathematical analysis tools were used which allowed for determining:

- average value of capital expenditures, revenues and expenses for one company
- percentage increases
- trend analysis based on linear regression analysis methods (Freedman, 2009)
- profitability ratios

It is worth noting the difference between the results published in this article and the generally provided data by the CSO in 2005-2011. The difference stems from the CSO's use of different formulas during this studied period. To calculate the gross profitability rate in some years CSO used the formula:

$$\text{Gross turnover profitability rate} = \frac{X}{Y} \times 100\%,$$

where: X - gross profit (for entities achieving a positive financial result); Y - total revenue.

For the purpose of enabling analysis of comparative data in the ten-year period, for all the years of 2003-2012 the following formula was used:

$$\text{Gross turnover profitability rate} = \frac{(Y - X)}{X} \times 100\%,$$

where: X – total expenses; Y – total revenue.

Potential contenders for the status of a listed company in Poland

Considering the operation of the stock exchange to focus on attracting new issuers also among the SMEs, the survey covered a period of 10 years of achievements of Polish entrepreneurship. Assuming the year 2003 as the base, it turned out that the number of companies in Poland increased by 4.0%, of which natural persons increased by 1.7%, and legal persons who are in light of the problem the most important group by 36.2%. For the sector of micro, small and medium-sized enterprises the statistics take the following values, respectively: 3.9%, 1.7% and 36.6%. Although their numbers cannot be called comparable (small enterprises increased from 42 770 in 2003, to 57 071 in 2012, microenterprises respectively from 1 666 696 to 1 784 603), among all segments surveyed the largest growth was recorded by small firms (33,4%), the smallest by micro-enterprises (3.1%).

Table 1. Number and growth rate of enterprises divided into legal forms and size sector in Poland in the years 2003-2012; 2003 = 100.00.

Source: own elaboration based on data from the CSO.

When analysing the sectors examined, it turns out that among natural persons the greatest appreciation was recorded by small enterprises (58.7%) and the smallest by large (-6.4%). Among legal persons, the highest growth was achieved by the segment of micro-entrepreneurs (49.1%), while the smallest by medium-sized enterprises (6.7%). There was, therefore, a strong increase in the number of companies with legal personality among all the structures observed on the market (micro: 49.1%, small: 15.7%, medium: 6.7%, large: 19.5%), which reached respectively in 2012 the

**Proceedings of the 8th International Conference on Applied Economics

18-19 June 2015, Economics and Finance**

number: 106 287, 29 075, 13 194, 3 099, which gives 151 655 companies having legal personality in Poland. SMEs therefore represent 98.0% of the entire collection, which has the ability to consider the stock exchange as a potential source of funding, with the specific involvement of micro-enterprises: 70.1%, small businesses: 19.2%, medium-sized entities: 8.7%, large companies: 2.0%.

Figure 1. Quantitative participation of companies having legal personality in Poland in the years 2003 to 2012.

Source: own elaboration based on data from the CSO.

In relation to 2003, among potential entities that may express interest in raising capital for development through the WSE there is a noticeable increase in the participation of micro-enterprises (by 6.1% in 2012) and a decrease of participation in other sectors: small (by 3.4%), medium (by 2.4%) and among large enterprises (by 0.3%), which take specific values presented in Tab.2.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

Compared to the average of the European Union, in Poland the SME sector is dominated by micro-enterprises, while small companies record a participation which is half of that of the EU. However, since 2008 their structure strongly increasingly resembles that of the EU (with a gradual decrease among micro-enterprises and increasing participation in other sectors) (PARP, 2014).

In 2011 the total number of companies in the EU-28 was 22 million. Most companies worked then in Italy, France and Germany (respectively, 3.8 million, 2.6 million, 2.2 million). Poland was in the sixth place in the EU before the Czech Republic, Portugal and Spain (respectively 1.0 million, 0.8 million, 0.8 million) with the number of 1.5 million enterprises (Eurostat, 2011)⁴. Striking is the number of companies registered in Italy, which exceeds the number of Polish by two and a half times.

Figure 2. Number of enterprises in countries of the EU in 2011 [in million]

Source: own elaboration based on data from PARP and Eurostat.

In the EU in 2011, 99.8% of enterprises were made up of micro, small and medium-sized enterprises, a result identical to Polish statistics (Eurostat, 2011)⁵. The difference can be seen in the individual segments, as micro-enterprises in the EU are 92.5% and 95.9% in Poland (among them

⁴ According to data from the CSO in Poland in 2011 the number of registered and active companies was 1 784 603, of which 142 968 companies were with legal personality, including 139 891 in the SME sector.

⁵ According to CSO data, in 2012 the number of companies increased by 10 340, of which 10 328 were in the SME sector, of which 8 665 are legal persons. Simultaneously there was an increase of 1 663 natural persons.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

legal persons make up 68.3%). Small companies have almost twice the share in the EU (6.2%) than in Poland (3.2%, including legal persons 20.1%) and only medium sized have a structure of comparable size (EU 1.0%, Poland 0.9%, legal persons making up 9.4%). The resemblance nearing the structure of the EU is seen throughout the whole studied period of 10 years and is very slow. Comparing the results from 2012 to 2003, there can be observed a decrease in the participation of micro-enterprises from 96.5% to 95.8% and an increase in the participation of other sectors creating the structure of SMEs: small from 2.5% to 3.2%, and medium from 0.8% to 0.9%. At the same time, large enterprises have increased their participation from 0.16% in 2003 to 0.18% in 2012 (PARP, 2014).

**Investments of potential contenders for the status of a listed
company in Poland**

Capital expenditures during the period considered in Poland have increased by 100%, while in the SME sector by 101.2%. Legal persons, who are the point of interest, spurred their financial contributions particularly among micro-entrepreneurs (145.7%), followed by medium-sized enterprises (103.2%) and small (47.9%). Large companies in the same period doubled their investments. The involvement of entrepreneurs in their own business noted a three times decrease, like those who represented the SME sector. However, two years are identical: in 2009 and 2012 the entire sector including micro, small and medium-sized enterprises reduced their investments accordingly to: PLN 69.1 billion and PLN 74.5 billion⁶.

When examining legal persons a sequence of declines was observed in consecutive years and receiving respectively values for all legal persons studied in 2009: PLN 125.8 billion, in 2010: PLN 123.2 billion, growth was not registered until 2012: PLN 133.9 billion⁷. The SME sector recorded a negative growth in the years 2005, 2009 and 2012, reaching, respectively: PLN 34.4 billion, PLN 51.5 billion and PLN 54.0 billion. When analysing this period in terms of companies' potential, which is a determinant of the possibility of cooperation with the WSE, worth mentioning are the achievements of small and medium-sized enterprises, as in 2010-2011

⁶ At the same time, the sector noted: PLN 143.7 billion in 2009, and PLN 154.8 billion in 2012. SME noted a third decline in capital expenditures in 2005, reaching a value of PLN 44.158 billion, and the whole sector in 2010 with a value of PLN 141.9 billion.

⁷ The value of capital expenditures in Poland in 2011 amounted to PLN 139.8 billion.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

their investment exceeded the commitment of large companies (by 1.0% and 0.5% respectively). This trend is not, however, reflected in the group of legal persons from this sector.

Figure 3. Capital expenditures by entities with a legal personality divided by sector in Poland in the years 2003-2012 [million PLN]

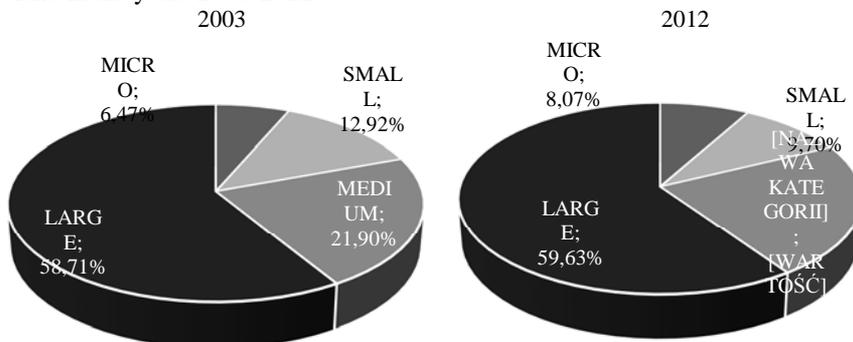

Source: own elaboration based on data from the CSO.

Comparing the initial and final results of the examined 10 years, it can be noted that only small companies among legal persons reduced their capital expenditures (by 3.2%). Other sectors increased their financial commitment to self-development (micro by 1.6%, medium by 0.7%, and large by 0.9%).

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?

Figure 4. The share of capital investments in companies with legal personality in Poland in the years 2003-2012

Source: own elaboration based on data from the CSO.

In summary, all sectors recorded an increase in financial involvement into their own investments. The most stable in this evaluation parameter is the micro-enterprise sector, which recorded a decline only in 2012 (by 26.5% to PLN 10.8 billion). Perhaps this is also due to so much interest in start-ups, which are currently recorded on the market (see: PARP, 2014; WSE, 2014). Other sectors decreased by three times the value of investment in relation to the previous year. Small businesses in the years 2005, 2009, 2012, by 11.5%, 15.0%, 9.0%, to the respective values of PLN 8.3 billion, PLN 12.8 billion, PLN 12.9 billion. Middle-sized enterprises in 2005, 2009 and 2010 by 1.0%, 11.7% and 2.2%, reaching values of PLN 19.9 billion, PLN 28.4 billion and PLN 26.8 billion. Large companies reported all decreases after 2008: in 2009, 2010 and 2012, by 13.3%, 5.7% and 0.1%, with the respective values of PLN 74.2 billion, PLN 70.0 billion and PLN 79.8 billion. The most obvious difference is provided by the results of medium-sized companies, achieved in one registration among legal persons by a company (Tab.3).

Comparing capital expenditures across the SME sector, noticeable is the much lower involvement of Polish entrepreneurs than that achieved in the EU. The best result for the EU-26 was achieved in 2011 by Austria of EUR 107.2 thousand, and the weakest by Portugal EUR 18.3 thousand. Poland was ranked sixth place again, but this time from the end (EUR 24.9 thousand), ahead of Bulgaria, the Czech Republic, Slovakia and Hungary.

Figure 5. Capital expenditure on fixed assets for one company in the EU-26 in the years 2008-2011⁸

⁸ Lack of data concerning Malta and Greece.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

For comparison, it is worth noting that in the same period in Switzerland, investments in fixed assets amounted to EUR 275.3 thousand and in Norway EUR 118.5 thousand.

**The structure of revenues and expenses of potential contenders
for the status of a listed company in Poland**

Analysing the structure of revenues it is tempting to theorize about the effectiveness of Polish entrepreneurship in the period considered. Despite the change in the number of enterprises by 4.0%, revenues increased by 192.9%, of which the SME sector reached a 170.8% increase and large companies 229.7%. However, further analysis shows that the structure and percentage trend of expenses is almost the same as that of revenues, especially among a selected group of legal persons whose revenue increased by 201.9% and expenses by 200.8%, reaching revenues of PLN 3.028 trillion and costs PLN 2.904 trillion⁹ (Tab.4). Thus, legal persons' revenues represent 80.4% of revenue of all registered enterprises in 2012, and the expenses 82.0%.

Table 4. Increase in revenues and expenses across sectors in Poland reached in 2012, in relation to 2003 [in %].

SPECIFICATION	INCOMS						COSTS					
	TOTAL	SME	MICRO	SMALL	MEDIUM	LARGE	TOTAL	SME	MICRO	SMALL	MEDIUM	LARGE

Source: own elaboration based on data from the CSO.

By submitting a detailed analysis of the data on these trends a higher growth rate of revenue of legal persons can be observed. The only exception is 2012, which reached a lower rate, however the values which stand behind these percentages show a pronounced difference, at 411.5% (revenues of natural persons in 2012 amounted to PLN 753.9 billion while legal persons PLN 3.028 trillion). Expenses tend to behave like revenue, reaching in 2012 a value of PLN 637.2 billion for natural persons and PLN 2.904 trillion for legal persons¹⁰.

⁹ Value of revenues of legal persons in 2003 amounted to PLN 1.499 trillion, and expenses PLN 1.447 trillion

Source: own elaboration based on data from the CSO.

In the analysed period, among legal persons a continuous upward trend was observed only among large enterprises. Larger entities of the SME sector registered two drops (small businesses in 2005, reaching a value of PLN 245.7 billion and in 2009 reaching a value of PLN 317.6 billion; medium-sized enterprises in 2009, reaching a value of PLN 601.9 billion and in 2012 reaching a value of PLN 705.8 billion). Micro-enterprises recorded negative growth three times: in 2005, with revenue of PLN 163.7 billion, and in 2011 and 2012 with the respective values of PLN 244.6 billion and PLN 241.4 billion. This is another one of the main reasons that should be taken into account when attempting to construct programs to encourage owners of companies from this sector to attempt to raise capital for development and opportunities to increase revenue through the stock exchange.

The expense structure is identical to that in the case of large companies, which systematically increase their commitment. Their decline is noticeable, with a halt at one level in 2008-2009 (respectively: PLN 1.241 trillion and PLN 1.229 trillion), however, since 2010 parities of this sector are constantly growing. Micro and small companies had a two times decrease in tendency in the years 2005 and 2009, reaching an expense value of respectively PLN 152.4 billion, PLN 219.9 billion, PLN 233.7 billion, PLN 301.6 billion. Medium-sized enterprises reduced expenses only in 2009 to PLN 574.0 billion.

Source: own elaboration based on data from the CSO.

Generally, revenues and expenses for large enterprises among legal persons grow. Only one decrease in expenses has been observed in 2009 at 1.0% to the prior year. Therefore, their financial results are much more predictable and the tendency of the financial result can generally be called as growing. Companies in the SME sector in their structure are more difficult to prognose, but the volume of their revenue rivals that of large companies. In the studied decade the revenue realized by micro, small and medium-sized enterprises, was even higher than in large enterprises (2003 and 2004). This trend has also been observed in the expense structure (Figure 6).

Figure 6. The revenues and expenses of legal persons in Poland in the years 2003-2012 [million PLN]. [●SME; ●LARGE]

Source: own elaboration based on data from the CSO.

Distinct differences were observed when comparing the values converted to one company in each sector. On average, each of the 3 099

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

legal persons among large companies had in 2012 a revenue of PLN 538.6 million, each of the 13 194 legal persons among medium-sized enterprises generated a revenue of PLN 53.5 million, every small company out of 29 075 legal persons on average recorded PLN 14.2 million in revenue, and micro-enterprises (106 297 companies) PLN 2.2 million. Accordingly the expenses amounted to PLN 515.6 million, PLN 51.5 million, PLN 13.5 million and PLN 2.2 million. Despite the glaring difference in values, noticeable is the systematic growth among small and medium-sized entities (except for 2009). Micro-enterprises do not maintain a uniform structure of revenue, even though the number of legal persons in the SME sector has the largest share, amounting to 71.5%.

In accordance with data from Eurostat and the European Commission developed for the needs of the SBA Fact Sheet 2012 they show clear differences in the growth rate of turnover of Polish companies and the average in the EU. The years 2005-2008 were much more favourable for Poland, because the dynamics of company turnover was 40.2% higher than in the European Union (Poland 162.1%, EU 121.9%) (EC, 2012). The years 2009-2012 showed the same trend, however, the proportion was reduced to the difference of 7.0% (Poland 126.0%, EU 119.0%) (Eurostat, 2011).

Gross financial result and the profitability of business entities in Poland

In 2012, the gross financial result of Polish companies increased in relation to 2003 by 207.9% to amount to PLN 275.8 billion earned by all registered and active business entities operating in Poland. Natural persons

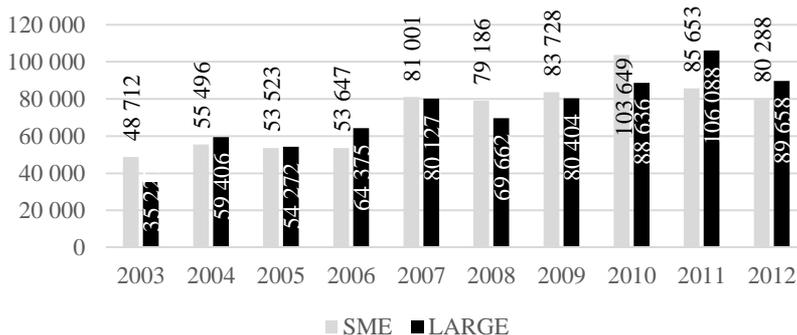

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

reached a 217.3% increase compared to the base year, with a value of PLN 105.8 billion. Legal persons a 202.5% increase and the amount of PLN 169.9 billion.

The SME sector in 2012 developed a result of 191.2% higher than in 2003 (PLN 185.5 billion in 2012.), among which legal persons increased their result by 164.8% (PLN 80.2 billion in 2012). Simultaneously large enterprises reached a 253.4% increase (PLN 90.2 billion), among them legal persons a 254.5% increase compared to 2003 (PLN 89.6 billion in 2012).

Examining the gross financial result achieved by SMEs and large companies in the years 2003-2012 an unambiguous trend cannot be determined, as in the years 2003, 2007-2012 micro, small and medium-sized enterprises achieved better results than large enterprises (respectively by: 38.3% 1.1%, 13.7%, 4.1%, 16.9%). In the years 2004-2006, this sector has reached values that are much lower (by 6.6%, 1.4%, 16.7%), as in the last two studied years 2011-2012 (by 19.3% and 10.5%).

Figure 7. Gross financial result achieved by legal persons in Poland in years 2003-2012 [million PLN].

Source: own elaboration based on data from the CSO.

The results of the entities included in the analysis, with each year reach a more heterogeneous structure. Small companies present themselves as most stable; in the analysed period they reached only two drops among legal persons: in 2004 and 2009 by respectively 13.6%, 12.7%, yielding values: PLN 15.3 billion and PLN 21.2 billion. Further subjects according to this criterion are large companies, which recorded three decreases: in 2005, 2008 and 2012 by respectively 8.6%, 13.1%, 15.5%, yielding values: PLN 54.2 billion, PLN 69.6 billion and PLN 89.6 billion. Micro-enterprises

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

in relation to the previous year recorded four drops: in 2005, 2008, 2011 and 2012 by respectively 1.3%, 13.0%, 36.2%, 21.4%, yielding values: PLN 15.2 billion, PLN 18.8 billion, PLN 23.6 billion, PLN 18.5 billion. The least stable among them are medium-sized companies whose gross financial result during the 10 years studied reached negative growth six times: in the years 2005-2006, 2008-2009 and 2011-2012, by respectively 7.3%, 9.7%, 3.8%, 1.6%, 12.3%, 4.8%, yielding values: PLN 22.9 billion, PLN 20.7 billion, PLN 36.0 billion, PLN 35.4 billion, PLN 37.2 billion, PLN 35.4 billion.

Source: own elaboration based on data from the CSO.

Performing a study allowing for comparison of obtained values of gross financial results, based on one company in a particular sector, it appears that since 2010 micro-enterprises on average achieve lower and lower results. Comparing the last three years studied, it was shown that negative growth occurred from year-to-year: in 2011 by 42.7% compared to the previous year, and another 27.8% in 2012. In fact, in 2012 micro-enterprises among legal persons increased their gross financial result compared to 2003 by PLN 0.02 million. Small enterprises have on average an (much larger than small companies) upward trend, but the results do not exceed 5.0%. Medium-sized enterprises showed the same trend as micro-enterprises, reducing their results by 12.2% in 2011 in relation to the previous year and a further 2.7% drop in 2012. Large enterprises, in terms of gross profit per company registered and operating actively in Poland in the years studied sequentially, also did not show a strong trend. Comparing the average gross financial results, of one company per sector examined in 2012, it appears that in relation to 2003 they reached a further increase of 13.9% by micro, 28.0% by medium, 65.7% by small, and 113.0% by large.

Source: own elaboration based on data from the CSO.

The productivity of enterprises in Poland, measured as results attributable to one employee or one company is significantly lower than the EU average (PARP, 2014). Polish companies, in accordance with the criterion of turnover per one employee occupy the 21st place in the EU-26. It has a similar position in the rankings for production or value-added services. Until 2008, Polish firms' productivity grew faster than in the EU, but in 2009 there was a significant decline in turnover per employee, which in subsequent years was again visible in trends, but to a much lower extent (2010 = 16.0%, 2011 = 7.4%, 2012 = 1.9%). The year 2010 was special for Poland, because its growth rate achieved 5th place among the EU countries (in 2011 it was 12th and in 2012 15th place in the ranking). Among the conducted analyses of

Poland against the EU it is also worth noting Poland's 7th place in the ranking of productivity of the EU-26¹¹ (Eurostat, 2011; PARP, 2014)¹².

Figure 8. The turnover per employee (in 2012 in thousand EUR) and growth rate (2011-2012) of turnover per employee in the enterprise in Poland and in selected European countries

Source: own elaboration based on estimated data from PARP, 2014, p.34.

Conclusions

The article attempts to answer the question of estimating the number of Polish enterprises that match the conditions to potentially debut on the WSE concerning their financial condition, with a particular emphasis on legal persons from the SME sector as well as to show the results achieved in Poland against the results of the EU.

Analyses show that the number of legal persons in Poland is steadily growing. The number of potential contenders to gain the status of a listed company and in this way to obtain financing to develop their own business among micro, small and medium-sized enterprises is 98.0% of the total collection. Among them, in relation to 2003, there was a systematic increase in micro-entrepreneurs (70.1% of the total in 2012), which may be a direct reflection of the increase in the number of start-ups observed in the

¹¹ Productivity is defined as the ratio of performance to expenses incurred.

¹² Paragraph applies to CSO data involving enterprises belonging to sections B-J, L-N, P-S of PKD 2007 (Polish Classification of Activities), Eurostat: B-N and S95 NACE Rev. 2 (section K is covered only partially and concerns insurance services, credit institutions and pension funds), European Commission (SBA Fact Sheet): B-J, L-N NACE Rev. 2.

capital market. In the remaining sectors, a decrease was observed in this legal form, thus it can be concluded that not too many transformations occurred from micro to small enterprises, small to medium-sized and medium to large enterprises. At the same time it was noted that the structure of these companies is becoming more like the EU, which bodes optimistically. In order to formulate more detailed conclusions, data taking into account the survival rate of companies with legal personality that are registered and actively operating in Poland should be subjected to analysis.

Capital expenditures for the same period increased among both small and large entities with legal personality, respectively by 192.5% among SMEs and by 200.0% among large enterprises. Entities of a legal personality from the SME sector contributed 40.4% of all finances involved in this respect in 2012, while increasing their commitment in this area by PLN 25.9 billion as compared with 2003. At the same time, however, they recorded a decline in the share, which in 2003 was 41.3%. Therefore, there are notable efforts to promote activation, with a parallel reduction of involvement among small companies (micro and medium-sized companies increased their shares, respectively, from 15.7% to 20.0% and 53.0% to 56.0%, and small decreased from 31.3% to 24.0%). This is another statistic which confirms an increased intensification of activities of micro-entrepreneurs, who gain thanks to the growing interest in the stock exchange. It is not determined, however, whether the result is reached by entrepreneurs with an established position in the market, or mainly the effect of newly established businesses, in the ranking of which Poland takes the leading place among the countries of the European Union.

Revenues of legal persons since 2003 are steadily growing among large entities, while maintaining variable trends in the SME sector. On the expenses side, significant for both sectors are the years 2008-2009, during which management reduced expenses, while at the same time worthy of note is the fact that for the whole sector of micro, small and medium-sized enterprises, there has been a direct impact on the value of the average expenses achieved by one company of the studied set, and among large enterprises expenses increased (in 2009 there was a decline in the number of legal persons among large enterprises by 3.9%). Simultaneously the best gross financial result was achieved by businesses in the years 2007 and 2010, and a clear trend was not seen among any of the studied sectors, each of them in relation to 2003 achieved growth on a minimum by 1.5 times (respectively by 169.8%, 148.1%, 176.8% and 254.5%).

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

Therefore, increasingly important are the results achieved by the SME sector, which increases its investments, revenues, expenses and profitability, consolidating its increasingly strong position and significantly affecting the macroeconomic size of Poland's economy. Precise determination of the volume of businesses that could raise capital for development through the WSE involves selecting from a set of legal persons enterprises registered as joint-stock companies and limited joint-stock partnerships of a survival rate of more than five years. The crucial problem is in fact the lack of official data and statistics dealing only with joint-stock companies and limited joint-stock partnerships, which is making it impossible to select and to determine exactly the economic condition and volume of businesses which are the basic target audience of the stock exchange, entities for which the way to obtain financing through the WSE is the shortest.

Doctrine of Public Good in Banking Versus State Intervention

JEL Classification: *G01; G21; H41*

Keywords: *bankruptcy; bank; crisis; financial institution; public good*

Abstract: This article has a following thesis: changes in banking and a role of banks in real economy in last years, give an argument for treating banks as public good.

Banks received a great support from governments as a result of the subprime crisis. G-20 and European Commission recommended new regulations for this sector after crisis.

As consequence of banking development more than 90% of population use banking services in many countries. New social functions of banks appeared. Doctrines about recovery and government support for banks were changed in parallel (e.g. LoLR). Presently there are some arguments for recognition of public good doctrine in banking such as: a very big area for state regulation, state banking supervision, state system of deposits insurance, realization of task delegated by the state, social responsibility of banks and others.

These arguments confirm that banks' activity has a particular importance for society and economy and would be public good.

Introduction

Presently financial services became common; for those who do not have access to them there are programs for counteracting financial exclusion.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

The new considerations for banking, new risks and new dimension for potential financial crises create a question whether the banking has become a public good. State intervention on a great scale during the subprime crisis indicates that the governments and international institutions treat banking as a special good. Not a single bank went bankrupt in Europe during last crisis.

Answers to the following questions seem to be important from the point of view of a banking company: what criteria should determine the public nature of financial services; what can be treated as public good in banking; should bank assume receiving public help in the event of crisis? Presently everyone agrees: a bank was and still is an institution of public trust.

The goal of this article is to prove that present banks should be treated as a public good.

Methodology of the research

In this paper the following scientific methods were used: national and international literature analysis, statistical analysis, comparative analysis and legal analysis.

Public goods – concepts, definitions, references to banking

A good is defined, as everything to what one can assign a positive value and at the same time is a value itself. (W. Krajewski, R. Banajski 1996) Different definitions of good in the general social meaning appear in the literature: common good, public good, impure public good, global public good, regional public good – in contrary to them there are private goods and so called club goods. Common and public goods may be considered as the same.

J. Buchanan named public good as a good that has two characteristics from the economic point of view: (Buchman J.M. 1968)

- it is a non-rivalry good – meaning that from the moment it is created and available it can be consumed by others without incurring any additional cost to anyone,
- it is a non-excludable good – meaning that the potential clients cannot be excluded from its consumption.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

Originally the public goods were associated with the ones financed (created) by the State; Presently junctim of terms such as subsidized, free and public goods is not justified. Some supporters of the public goods theory think that creation of public goods may successfully happen in private sector, yet the majority's opinion those goods are created thanks to the State's activity (R. A. Musgrave, P. Samuelson). (Fijor J. M. 2011)

P. Samuelson defines current shape of the public goods concepts; they mean that there is no rivalry expressed by the joint delivery of a good and ineffectiveness in attempts to exclude anyone from its consumption. (Samuelson 1954)

Public goods issue is present in economic literature for a century; national currency and stable prices are considered to be public goods. In J.K. Solarz's opinion today "there's a space for dialogue about public goods in financial sector instead ruling of the market or the State". Thesis presented already in 1992 by G. Corrigan: banks are perceived not only as public trust institutions, but even broadly as public good; therefore whole society should bear the costs associated with it (system risk is a whole society's risk) – caused lots of discussion and criticism. (Corrigan 1992)

J.K. Solarz created a typology of financial services as public and private goods. (Solarz 2008, p. 159) The purposefulness of such classification for policy towards banking is important and necessary; even though assignment of goods to particular types is questionable. However, one should consider volatility of the matter; for instance the ongoing democratization of brands. In this author's opinion blurring in practice the distinction between public and private goods in financial sphere causes theoretical disputes around that who is to blame of market or state inefficiency; therefore an intermediate category of impure public goods is growing. (Solarz 2008, p. 158)

It should be considered, what may and ought to be a public good in banking? Few options may be mentioned here:

- whole banking industry (loans and deposits institutions),
- only universal banks,
- only the safety of client deposits,
- only the retail customer's operations or selected products,
- system stability or institutional system of its protection (e.g. Financial Safety Net in the EU),
- common and small scale operations (e.g. up to the amount of 50 thousand EUR in the EU within the framework of deposit insurance).

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

In W. Szpringer's opinion, the public good category may be applied to the banking system, not to the individual bank that may go bankrupt after all. (Szpringer 2001, p.11)

A. Greenspan treated financial stability as a public good. He stated that the LoLR function is and will be essential because "the markets mostly work efficiently but from time to time they collapse. When it happens the State's intervention is necessary in order to preserve stability, which is a public good". (Greenspan 1988) If one should recognize that banking is a public good only in the event of crisis – questions arise whether it should be in the event of system or individual bank's crisis; what to consider as conditions of crisis; what level of public help is allowed? It seems that the licensed banks should be treated as public good.

Banking and state intervention

W. Bagehot's doctrine (19th century) stipulated that in bank crisis - the central bank or the government becomes the essential Lender Of Last Resort (LoLR). In compliance with this doctrine central banks of many countries took the LoLR role on themselves. S. Heffernan thinks that "if LoLR judges that the source of the problem is run or bank panic, not the financial situation of the bank, it may lower its requirements concerning capital adequacy and apply smaller penalty interest rate. As a matter of fact, arguments for LoLR existence resemble nuclear bogeyman: it is a tool that is meant to prevent panic that could happen." (Heffernan 2007, p. 574) During subprime crisis FED, ECB and central banks of the EU countries broadly performed LoLR function. (Masiukiewicz 2008) The first institution to take up function of international LoLR was the International Money Fund, by granting credit line for countries affected by financial crisis in the 90'.

20th century was quite rich in banking crises. At the same time the development dynamics, social reach of banking and attempts to calculate social costs of bankruptcy (E. Altman) were undoubtedly the causes of wide spreading new doctrines. Ch. James' research indicated that liquidation of insolvent banks is more expensive than its recovery, takeover by healthy bank or even nationalization. (James 1991) E. Gardener and P. Molyneux gave much attention to the "Too Big To Fail" (TBTF) and "Too Important To Fail" (TITF) doctrines. (Gardener, Molyneux 1998) Those authors were proving that due to the importance for the system risk, some banks (so called strategic) deserve rescue by the State (not excluding nationalization), and doctrines TBTF and TITF became practice. (Gardener,

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

Molyneux 1998) Opponents of such approach stated on the other hand that this certainty about public bailout would lead to strengthening moral hazard.

In the end of the 20th century a new approach appeared in the literature, treating financial stability, as well as the banks themselves as public good (G. Corrigan, S. Heffernan, P. Krugman, J.K. Solarz, J. Stiglitz); what would justify its bailout during crisis. (Masiukiewicz 2010(2))

G. Kaufman defined banking crisis as a situation that is characterized by bank run, financial institutions collapses or massive state intervention as well as broad disruption of safety of other institutions. (Kaufman 1999) This definition clearly focuses on elements of panic and state help in crisis. System risk and threat of panic epidemic – according to the S. Heffernan – are the key causes to the State for having inclination to special treatment of banks, and to central banks for serving as the LoLR or delivering, so called, lifeboat rescue operation. (Hefernan 2007, p. 41)

There are many cases – what is proved by crises history – in which central banks and system regulators were intervening to save individual bank or group of banks; protecting at the same time other entities of the financial system. (Hefernan 2007, p. 209) J.K Solarz claims that the banking crisis (and social response) may even force authorities to intervene and provide significant help to this sector. (Solarz 2008, p.101) Financial crises showed how far governments can go to prevent bank from collapsing, how broadly doctrines TBTF and TITF can be applied. (Hefernan 2007, Gardener, Molyneux 1998) As a part of the fight against subprime crisis, governments and central banks of USA and Europe reached for the most radical measures, including nationalization of financial institutions and using vast funds from taxpayers. (Krugman 2008) Even D. Strauss-Kahn (former president of the IMF) sided for the interventionism: “necessity of public intervention becomes even more obvious. Government intervention – regardless whether it’s on securities or real estate market or banking industry – would act as “third line of defense” supporting the fiscal and monetary policies”. (Guha 2008) In M. Diekmann’s opinion (the then president of the Allianz Group) the debate should focus not on whether the state should intervene, but rather on how to do it. (Diekmann 2008)

Also the experience of polish banking crisis from the 90’ clearly indicate that without subsidies (as a restructuring bonds) and tax reliefs many banks would go bankrupt causing domino effect, i.e. enterprise bankruptcy.

New measures of the European Commission are introduction of CRD/CRR directives that tighten norms of banks operation and preparation

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

of draft of the resolution and recovery regime procedure for big banks – that enables scheduled liquidation; that is to not allowing a sudden collapse. (Masiukiewicz 2013(2)) A new concept is also a creation of Banking Union as a part of the EU. (Masiukiewicz 2013(3))

Also a question arises about admissibility of public aid for banks in the EU countries. W. Szpringer points out that the member countries that bailout threatened banks are not only bound by the art. 87-89 of TEC, but also by the instructions of the European Commission regarding rules of public aid for financial institutions in connection with the global financial crisis. (Szpringer 2009(2), p. 23) One of the forms of States' aid for financial sector are the government guarantees for banks' liabilities. The guarantees relate usually to all retail deposits and selected categories of wholesale deposits as well as medium term debt instruments.

European Commission announced new guidelines for recapitalizing financial institutions by governments. They stipulate that the capital aid from the State cannot affect competitive advantage of banks from one member country over institutions from another EU countries. (Szpringer 2009(1), p. 24) Implemented in 2008, the European Plan for Economic Recovery, even though it did not bind anyone was treated as additional guideline for admissibility of public intervention aid. (Szpringer 2009(1), p. 25) After sub-prime crisis many EU countries founded Recovery Funds, also in Poland, the bill on Banking Guarantee Fund (BFG) provides possibility aid for banks and credit unions in form of a long term loans for recovery programs in the event of crisis. (Masiukiewicz 2013(1))

Economics theorists recently express a need for redefining role of the State in the economy – in the circumstances of global companies and products, global shortages and global crises. G. Rae presents a thesis that the State has to return to the subjective role in the united Europe's economy; also laying out a number of arguments supporting it. (Rae 2008)

Regarding banking industry, there are opinions claiming its overregulation by the State. Basel III recommendation and CRD/CRR directives introduced a number of new limits on banks, and the regulators have rights to accept a president and vice president, to accept shareholders with more than 10% shares of the bank, to ban selling selected products, may also suspend the bank, liquidate it or compulsorily merge it with another bank as well as number of other rights. (Masiukiewicz 2013(1))

It is necessary to point out that the consequences of new banking crises may be only comparable to the costs of nuclear strike; it is estimated that

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

the medium size banking crisis costs about 15-20 % GDP – for which taxpayers will pay (Masiukiewicz 2009).

Arguments for and against recognizing banking as public good

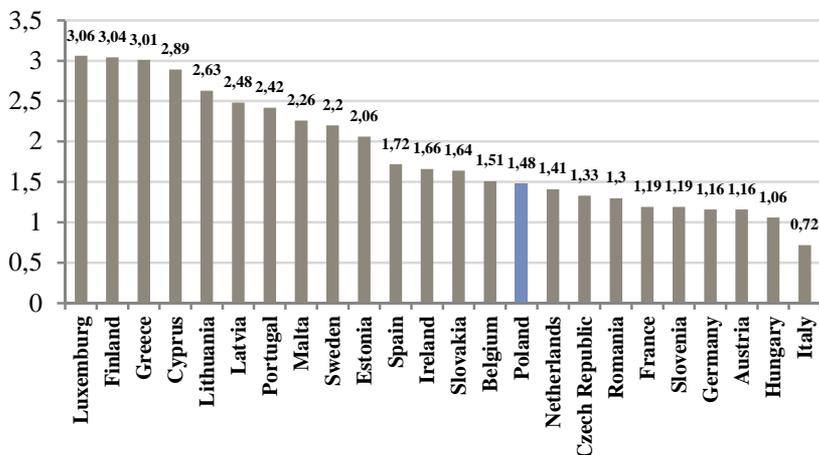

Recently in literature some researchers raise the issue of social responsibility of banks and costs related to their quasi-social mission. The following are typical costs that banks cover in this area nowadays:

- costs of restructuring bankrupting enterprises,
- risk and costs of premature deposit withdrawal by customers (bank run),
- costs of maintaining customer deposit insurance system,
- crediting endeavors in area of public procurement and public-private partnership,
- granting preferential loans (agricultural, student, environmental and other),
- costs of overdue receivables from public institutions and economic consequences of consumer bankruptcy for banks,
- costs of counteracting financial exclusion that is recommended by authorities (e.g. in EU).

A significant argument for considering banking as public good is the level of access to and use of banking services. Provided in 19th century 1-5% of society had access to financial services, presently in highly developed countries banking access indicator reaches 95% (in Poland 80%), and the number of accounts per capita surpassed 1 long ago (graph 1). Highly developed countries implement governmental programs to counteract with financial exclusion – to achieve banking access factor close to 100%. For instance, in some EU countries central bank may assign duty to open bank accounts to homeless and poor. Presently broad access to financial services, assurance of funds safety, and facilitations in performing transactions and cash flows cause that in highly developed countries it is nearly impossible to function without bank.

New, characteristic functioning circumstances of modern banking indicate its risks and its role in maintaining financial stability, therefore also indicate a need for public protection. New opportunities and threats for banking industry are presented in the table 1.

Table 17. Opportunities and threats of modern banking

#	New threats	#	New opportunities
1	Widespread of banking services – amounting to 90% of population determines possible scale of crisis consequences to citizens,	1	Rebuilding trust towards banks
2	Globalization of operations causing easier transmission of crisis threat,	2	Increasing demand from SME's for credits and possible opportunities (especially in developing countries)
3	Range increase of electronic banking, creating new areas of threats,	3	Creating Financial Safety Net – FSN, including repair funds for financial institutions
4	Increase of importance of financial advisory and rating institutions, and at the same time lack of sufficient supervision and scope of their liability,	4	Expanding tasks for national financial regulators and creating European Banking Authority
		5	
		6

Source: Own.

Growth financing, safety of citizen and corporate savings, development of international exchange are served by banks and therefore dependent on bank's standing and more broadly on credit-depository institutions' standing.

Elementary arguments for treating banks as public good are the following (Masiukiewicz 2010(1), Masiukiewicz 2010(2)):

- functions of banks that assure economy and households growth,
- special legal regulations and licensing of banking activity (de Larosiere report that was accepted by the European Commission recommended increasing regulations after subprime crisis),
- public trust as the operation attribute (strengthened institutionally by the State),
- public deposit insurance system,
- setting many market parameters for banks by the State (reference interest rates, reserve ratio, maximal interest rate for consumer credits etc.),
- broad supervisory rights for regulators; broadened even further towards banks in critical situation (orders and bans for banks),

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

- performing by selected banks state delegated functions and function of restructuring overdue liabilities of enterprises and households,
- operations openness, mass media access to the information – what may in special cases used against the bank,
- banks' high sensitivity for crises and contagion effect (therefore a possible influence on destabilization of whole financial system),
- system of public institutions appointed to protect financial customers (financial supervisors, deposit insurance fund, bank customers' ombudsman, compulsory administration and other),
- bearing costs of maintaining financial safety net as well as costs of bank bankruptcies by taxpayers – customers.

One can also lay out number of arguments against it, among others they are:

- functioning in free market,
- customer's freedom of choice of bank,
- general prohibition of public aid for enterprise in the EU (although with exceptions),
- risk of political pressure concerning scope and structure of public aid for banks,
- moral hazard of management; granting public aid to bank was not always connected with consequences for then top managers.

Problems connected with the matter of concerning banks as public good and consequences of public aid require further research and discussion. Yet in the end it will be up to national and european authorities to decide on voters' behalf about approach and policy regarding this matter.

Conclusions

Common access to banking, its role in financing country's development and at the same time experiences from the number of international crises and bank bankruptcies indicate broad social consequences of possible bankruptcies and justify applying doctrine of concerning banking as public good and state intervention connected with that.

As a consequence of treating banking as public good perhaps it ought to function in the citizen's interest, be under protection and supervision of the State. It also means limiting market influence on this industry, possibility of providing services by the State industry or nationalizing part of the banking industry in a financial crisis. Operations of banks should be based on the Corporate Social Responsibility (CSR) concept.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

Treating banking as a public good creates a social and economic justification for:

- strengthening public trusts towards banks,
- state co-financing of deposit insurance system,
- using financial supervisory and regulatory instruments in the interests of the citizens,
- building national and european Financial Safety Net (FSN) and providing aid to the banks in critical situation,
- ensuring common access to financial services (elimination financial exclusion).

Further research of problems connected with the issue presented in this article should among other things answer following questions: how strongly regulated banking industry should be, what instruments of restructuring should be used during system crisis and what are the limits of growth of big global banks and who should supervise them? Protection of financial safety of households and enterprises should be main goal and criterion of State policy in discussed matter.

**Net Profit Distribution Policy in Companies
Using State–owned Enterprises
Against Payment***

JEL Classification: *G32; L33*

Keywords: *privatisation process; direct privatization; using state–owned enterprise against payment; net profit distribution policy; pecking order theory*

Abstract: The main objective of this paper is to present the results of empirical studies on net profit distribution in companies using state–owned enterprises against payment. The main research hypothesis states that the majority of companies using state–owned enterprises against payment waive their right to the dividend and transfer a major part of retained earnings to supplementary capital. The empirical investigation of the main hypothesis has been conducted among 21 companies based in Mazowieckie Province, which concluded privatisation agreements with the State Treasury in years 2000–2005. The analysis of net profit distribution in companies using state–owned enterprises against payment is based on data collected and processed by the author of the article from the National Court Register, for the period from the privatisation date of the surveyed enterprises to 2010, using measures of descriptive statistics. The paper consists of the following parts: the introduction, the essence of giving state–owned enterprise for use against payment, the characteristics of companies qualified to the research sample, net profit distribution policy in companies using state–owned enterprises against payment. Final-

* The publication is co–financed from the funds of donations for the projects fostering the development of young scientists and doctoral students.

**Proceedings of the 8th International Conference on Applied Economics

18-19 June 2015, Economics and Finance**

ly, it is concluded that over the first three years of operation every second company using a state-owned enterprise against payment did not pay a dividend transferring all of retained earnings to supplementary capital.

Introduction

Giving a state-owned enterprise for use against payment to a company is the most employee oriented way of privatisation in Poland (see Błaszczyk, 2002, p. 193). The specific character and scale¹ of giving state-owned enterprises for use against payment to companies with employee share ownership (compare Aghion & Blanchard, 1998, pp. 96–97; Bornstein, 1997, p. 329; Lowitzsch, 2006, pp. 132–134, 160–162, 253–255; Kozarzewski, 2006, pp. 124–125) result in achieving social and economic objectives of the ownership transformation process (see Balcerowicz, 1997, p. 218; Bałtowski, 2002, pp. 17, 30; Brozi, 1993, pp. 17–18, 32–34; Prusek, 2005, pp. 5–17; Sobolewski, 2011, pp. 43–53).

Obligations to the State Treasury arising from the business activity of companies using state-owned enterprises against payment is a significant factor. The excessive burden on companies in respect of using state-owned enterprises against payment and the lack of ownership of the assets of the acquired enterprises during the agreement period with the State Treasury negatively affect their credit capacity, limiting their ability to obtain loans for the financing of development investments (see Bojar et al., 2003, pp. 89, 95, 98, 106, 109, 111; Jarosz & Kozak, 1995, pp. 118–125; Wrońska, 2004, pp. 127, 129, 135, 137, 141, 161). Therefore companies using state-owned enterprises use equity capital² as their source of financing (compare Brealey et al., 2001, pp. 508–509; Duliniec, 1998, pp. 32–34; Duraj, 2000, pp. 201–203, Frank & Goyal, 2003, p. 241; Gajdka, 2002, pp. 230–248; López-García & Sogorb-Mira, 2008, p. 133; Myers & Majluf, 1984, pp. 219–220, Serrasqueiro et al., 2011, p. 381). Moreover, the fear among employee owners of losing control over the company or a hostile takeover (compare Damodaran, 2007, pp. 872–873; Ickiewicz, 2004, p. 206; Safin, 2003, p. 45) and the conditions that must be met to obtain deferred additional fees exemption, as debt interest held by the State Treasury, may lead

¹ Poland was the only country in Central–Eastern Europe in which manager–employee buy–out pursued in the form of lease leverage employee buy–out developed on such a large scale.

² According to the pecking order theory, especially useful in understanding small and medium–sized enterprises' capital structure, companies prefer internal funds, such as retained earnings, as their source of financing.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

not only to the company being financed through retained earnings but also to allocating a substantial part of retained earnings to the company's supplementary capital.

The main objective of this paper is to present the results of empirical studies on net profit distribution in companies using state-owned enterprises against payment. The main research hypothesis of the article states that the majority of companies using state-owned enterprises against payment waive their right to the dividend and transfer a major part of retained earnings to supplementary capital. The empirical investigation of the main hypothesis has been conducted among 21 companies based in Mazowieckie Province, which concluded privatisation agreements with the State Treasury in years 2000–2005. The analysis of net profit distribution in surveyed companies is based on data collected and processed by the author from the National Court Register.

The methodology of the empirical research, the essence of using state-owned enterprise against payment, the companies qualified to the research sample are discussed further on in the study. The main research conclusions were formulated in the Conclusions section.

Methodology of the research

The empirical research on net profit distribution in companies using state-owned enterprises against payment has been carried out among companies, which concluded privatisation agreements with the State Treasury in years 2000–2008. Defining the period during which companies concluded agreements with the State Treasury was due to the following reasons:

- empirical research on companies using state-owned enterprises against payment already carried out did not go beyond 2000 (see Kozarzewski & Woodward, 2001),
- the need of analysis of net profit distribution policy in companies using state-owned enterprises against payment during at least the five-year research period after the year in which the agreement with the State Treasury was concluded³.

³ In case of companies using state-owned enterprises against payment which concluded the agreement with the State Treasury in 2008 the analysis of net profit distribution is carried out with respect to years 2008–2013.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

The empirical research on net profit distribution policy has been carried out in companies using state-owned enterprises against payment⁴ from Mazowieckie Province, where most such entities were established from the beginning of the privatisation process to the end of 2010. According to the data from Central Statistical Office in Poland (GUS), 190 employee companies were established in Mazowieckie Province from 1990 to 2010 (compare Baehr, 1993, pp. 51–52; Górka, 1991, p. 91; Nadratowska, 1990, p. 54; Włodyka, 1996, pp. 657–663), amounting to 12.16% of all companies established during the period of ownership transformation in Poland (see *Prywatyzacja przedsiębiorstw państwowych w 2010 r.*, p. 59).

According to the data from the Ministry of the Treasury, from 2000 to 2008, 29 agreements of giving a state-owned enterprise for use against payment were concluded in Mazowieckie Province, none of which was concluded after 2005. From 29 companies based in Mazowieckie Province, which concluded privatisation agreements with the State Treasury in years 2000–2005, companies using state-owned enterprises against payment were excluded:

- companies in liquidation and under bankruptcy (2 entities),
- enterprises undergoing transformation of the organizational–legal form⁵ (3 entities),
- established before the implementation of the new Privatisation Law⁶ (3 entities).

Eventually, 21 Mazowieckie Province–based companies using state-owned enterprises against payment, which concluded privatisation agreements with the State Treasury in years 2000–2005, were qualified as the research sample.

The analysis of net profit distribution in companies using state-owned enterprises against payment was carried out on the basis of documentation of the surveyed companies submitted to the National Court Register, for the period from the privatisation date of the companies to 2010. The date of privatisation is the date of the agreement with the State Treasury giving rise to the submission of an application for removal of the state-owned enter-

⁴ Companies established to lease the assets of directly privatised and liquidated state-owned enterprises (lease leverage employee buy-out) are commonly referred to as employee companies.

⁵ Three limited liability companies were converted into limited partnerships during the research period.

⁶ The Act of August 30, 1996 on Commercialisation and Privatisation (Journal of Laws No. 171/2002, item 1397 with subsequent amendments) repealed the previous act in this respect as of 8 January 1997.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

prise, whose assets were given for use against payment, from the Register of Entrepreneurs (Ustawa z dnia 30 sierpnia 1996 r., DzU 2002e, Article 42 (2)). The period from the privatisation date to the end of the year in which it occurred is treated as year $t = 0$ (year of privatisation).

Measures of descriptive statistics, i.e. classical and positional measures of dispersion and measures of position were used in the empirical research of net profit distribution policy in companies using state-owned enterprises against payment.

The essence of giving state-owned enterprise for use against payment to a company

Giving state-owned enterprise for use against payment to a company is one of three direct privatisation methods consisting in the disposition of all tangible and intangible component assets (Ustawa z dnia 30 sierpnia 1996 r., DzU 2002, Article 39 (1)). The subject of the direct privatisation through giving state-owned enterprises for use against payment may be entities which fulfil the following conditions⁷ (compare Grzeszczyk, 1997, p. 231; Surdykowska, 1996, p. 39; Ustawa z dnia 30 sierpnia 1996 r., DzU 2002, Article 39 (2)):

- the sales value of goods and services in the year preceding the year of issuing a privatisation order is not higher than the PLN equivalent of EUR 6 million,
- the sales value of goods and services in the year preceding the year of issuing a direct privatisation order is not higher than the PLN equivalent of EUR 2 million⁸.

Giving state-owned enterprise for use against payment to a capital company may take place if (Ustawa z dnia 30 sierpnia 1996 r., DzU 2002, Article 51 (1, 2)):

- more than half of the employees of the privatised state-enterprise joined the company,
- shareholders are only to natural persons, unless the Minister of the Treasury will allow the participation to legal persons in the company,
- paid-up share capital of the company shall not be lower than 20% of the

⁷ The direct privatisation through giving state-owned enterprise for use against payment is designed for small and medium-sized enterprises.

⁸ The PLN equivalent is calculated by the purchase rate announced by the Polish National Bank on 31 December of the year preceding the year of issuing a direct privatisation order.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

founding capital and the enterprise capital at the date on which balance sheet for the financial year, preceding the year of issuing the direct privatisation order, was drawn up,

- at least 20% of the shares have been acquired by persons not employed in the privatised state-owned enterprise⁹.

Giving state-owned enterprise for use against payment shall be effected by the agreement between the State Treasury and the established company for a period not exceeding¹⁰ 10 years (compare Ustawa z dnia 5 grudnia 2002 r., Article 2 (15), Article 25). In the agreement of giving the state-owned enterprise for use against payment, the parties may decide that the ownership of the enterprise is transferred to the transferee after the period for which the agreement was concluded and upon fulfilment of the conditions specified in the agreement. The ownership of the enterprise may be transferred before the expiry of the period for which the agreement was concluded after the payment by the transferee at least one-third of liabilities to the State Treasury and the approval of the financial statement for the second financial year from the date of the conclusion of the agreement. The remaining part of the liability, bearing interest at¹¹ the price index of investment goods¹² lowered not less than a half percentage points¹³, is paid in instalments (compare Rozporządzenie Rady Ministrów z dnia 16 października 1997 r., §8 item 3; Teluk & Wojnowicz, 1999, p. 38–39; Ustawa z dnia 12 maja 2006 r., Article 1 (12), Article 11; Ustawa z dnia 30 sierpnia 1996 r., DzU 1996, Article 52 (2–4)).

The contractual value of the state-owned enterprise given for use against payment is the basis for determining the commitments for using the enterprise (Rozporządzenie Rady Ministrów z dnia 16 października 1997 r.,

⁹ The Minister of the Treasury may consent to give the state-owned enterprise for use against payment to a company which does not fulfil the requirements of the acquisition of 20% of shares by persons not employed in the privatised state-owned enterprise

¹⁰ From 15 January 2003 the agreement between the State Treasury and the company established to use the state-owned enterprise against payment may be concluded for a period not exceeding 15 years.

¹¹ From 28 July 2006, in the event of the transfer of the enterprise before the expiry of the period for which the agreement was concluded, the remaining part of the liability to the State Treasury bear interest at not less than the price index of investment goods.

¹² The price index of investment goods is published on a quarterly basis by the President of the Central Statistical Office of Poland in the Official Journal of the Republic of Poland “Monitor Polski”.

¹³ The reduction of the price index of investment goods depends on the degree of implementation of non-price commitments consisting of commitments in terms of investments, environmental and cultural protection and job protection.

Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

§2). In agreements concerning giving the state-owned enterprise for use against payment, in which transfer of the ownership to the company is provided for, the commitment for the use of the business assets cannot be lower than the total sum of (Rozporządzenie Rady Ministrów z dnia 16 października 1997 r., §3):

- the value of the enterprise paid in capital instalments – the quotient of the value of the enterprise and the numbers of year quarters, for which the agreement was concluded,
- the sum of additional fees for the duration of the agreement – the product of the value of the enterprise reduced by paid capital instalments and an interest rate¹⁴ of 0.5 of the current lombard rate¹⁵ (compare Dodatkowe wyjaśnienia dotyczące nowej metody ..., pp. 1–2; Komunikat Komisji w sprawie zmiany metody ..., p. 8; Rozporządzenie z dnia 14 grudnia 2004 r., §7 item 1; Obwieszczenie Komisji w sprawie metody ..., p. 3; Obwieszczenie Komisji w sprawie bieżących stóp ..., p. 13; Zawiadomienie Komisji w sprawie bieżących stóp ..., p. 2).
Moreover, additional fees in such agreements can be paid¹⁶:
- in the first four quarters of the duration of the agreement in the amount of one-third of their value estimated for a given period.
- in the next four quarters of the duration of the agreement in the amount of half their value estimated for a given period,

¹⁴ From 22 December 2004 the interest rate of the unpaid part of the value of the enterprise cannot be lower than the reference rate periodically fixed by the European Commission for Poland. From 1 July 2008 the European Commission does not publish the reference rate but fixes the base rate increased by a relevant margin to provide the reference rate. The amount of the margin depends on the enterprise's rating and the offered level of assurance. The new method of the base rate determination, by adding the margin relevant to a particular company to the base rate fixed by the European Commission, reflects the method of determining the borrowing rate in market conditions. Using a lower interest rate of the unpaid value of the enterprise than the reference rate of the European Commission, treated as a market rate, may be treated as an unjustified public aid.

¹⁵ The lombard rate is determined by the President of the National Bank of Poland (NBP). If the lombard rate exceeds 40%, the amount of the liability updated at the date of the rate's change is assumed in the amount equal to 40%.

¹⁶ From 2 June 2006 deferral of capital instalments or additional fees that have not yet fallen due and the possibility of division into instalments of the payments that were due may be specified in the agreement of giving a state-owned enterprise for use against payment. The amendments to the provisions of the agreement concerning deferral of capital instalments or additional fees, or division into instalments of the payments is public aid for restructuring purposes.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

The difference between charged and paid value of additional fees for these periods increases the value of the company's liability to the State Treasury and is quarterly paid without capitalizing in equal instalments from the third year till the end of the period of the agreement (compare Rozporządzenie Rady Ministrów z dnia 16 października 1997 r., §5 item 2, 3; Rozporządzenie Rady Ministrów z dnia 25 kwietnia 2006 r., §1 (3), §9).

The company may be exempted¹⁷ from the debt arising from deferral of additional fees if in the year of the agreement or in two years in total (compare Rozporządzenie Rady Ministrów z dnia 16 października 1997 r., §5 item 5, 6; Rozporządzenie Rady Ministrów z dnia 25 kwietnia 2006 r., §3 item 2):

- the net profit write-offs allocated to supplementary capital amounted to at least 80% of the profit,
 - commitment for the use of the business assets of the state-owned enterprise was paid within the maturity date,
 - the company will agree not to allocate the supplementary capital to the share capital within three years of the exemption,
 - the company will not transfer shares to the shareholders of the company.
- The value of exemption from the debt may not be higher than the net profit write-offs allocated to supplementary capital in the year of the agreement or in two years in total and it the commitments to the State Treasury (Rozporządzenie Rady Ministrów z dnia 16 października 1997 r., §5 item 4).

The characteristics of companies qualified to the research sample

The majority (17 companies) from 21 companies using state-owned enterprises against payment qualified to the research sample are entities whose value of the subject of the agreement with the State Treasury exceeded PLN 1 million.

¹⁷ From 28 October 2005 exemption in the amount of two thirds of additional fees payable in the first eight quarters of the year without its prior deferral is possible within the framework of regional aid for new investments.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

Three companies – *Geokart Sp. z o.o.*, *Polmos S.A.* and *Bipromel Sp. z o.o.* – concluded agreements of giving the state-owned enterprise for use against payment for a period shorter than the maximum allowed, whereas the other three – *Przedsiębiorstwo Robót Drogowo-Inżynieryjnych S.A. w Mławie*, *Elektroprojekt S.A.* and *Tarczyn Sp. z o.o.* – extended the duration of the agreement from 10 years to 15 years.

Two companies – *Biprodrzew S.A.* and *Bipromel Sp. z o.o.* – used state-owned enterprises against payment under the conditions determined by The Ordinance of the Council of Ministers of December 14, 2004 on terms of payment for amounts due on the use of the enterprise (Journal of Laws No. 269, item 2667)¹⁸. Additional fees were set for the companies using the reference rate without deferred payment option specified in the agreement concluded with the State Treasury.

Eleven companies using state-owned enterprises against payment from these, which concluded agreements with the State Treasury with deferred payment option, were exempted from the debt. One company – *Zakład Transportu Energetyki „ZTiSZE” Sp. z o.o.* – was partially exempted from the debt arising from deferral of additional fees because the value of the net profit allocated to supplementary capital did not cover the volume of the debt.

In the majority of cases after the prior transfer of the ownership of the enterprise, the remaining part of the commitment to repay was subject to the price index of investment goods reduced by 0.1 percentage points. Applying this interest rate resulted in public aid grant (see Ustawa z dnia 30 czerwca 2000 r.), which was devoted to improving financial liquidity or investment projects.

Four companies using state-owned enterprises against payment – *Morspol S.A.*, *Elmet Sp. z o.o.*, *Geokart Sp. z o.o.* and *Polsport Sp. z o.o.* – obtained the right of ownership of the enterprise after the payment of all commitments to the State Treasury. In case of three companies the payment was made before the expiry date of the agreement¹⁹. As of 31 December 2010, twelve agreements of giving a state-owned enterprise for use against

¹⁸ The conditions of giving the state-owned enterprise for use against payment to a company are determined by The Ordinance of the Council of Ministers of December 14, 2004 on terms of payment for amounts due on the use of the enterprise (Journal of Laws No. 269, item 2667), which repealed the previously applicable ordinance from 22 December 2014.

¹⁹ In 2007 one company – *Biprodrzew S.A.* – not only made use of the possibility to obtain the right of ownership of the enterprise before the expiry date of the agreement but also made the payment for using the state-owned enterprise.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

payment were valid. Two entities from the research sample – *Bipromel Sp. z o.o.* and *Biuro Studiów i Projektów Budownictwa Ministerstwa Spraw Wewnętrznych Sp. z o.o.* – did not own the enterprises (see table 1).

**Directions of net profit distribution policy in companies using
state-owned enterprises against payment**

In the research period, 10 of 21 companies using state-owned enterprises against payment have never paid the dividend. Seven companies of these, which did not pay the dividend, achieved positive financial results within the whole research period. Two companies – *Wyszowskie Centrum Materiałów Budowlanych Sp. z o.o.* and *Biuro Studiów i Projektów Budownictwa Ministerstwa Spraw Wewnętrznych Sp. z o.o.* – did not pay dividend as a result of generating net losses. One company – *Wyszowskie Centrum Materiałów Budowlanych Sp. z o.o.* – allocated the net profit generated in the period $t = 5$ to cover the losses from the previous years.

In period $t = 0$ (the year of privatisation) only two companies using state-owned enterprises against payment – *Polmos S.A.* and *Biprodrzew S.A.* – paid dividend. The company – *Polmos S.A.* – paid dividend every year during the research period exceeding 35% of the net profit for a given year. In the next two years following the year of privatization seven companies using state-owned enterprises against payment paid the dividend, three of them paid the dividend every year. After the period $t = 3$ eleven companies decided to pay dividend from the net profit generated in a given year.

Only one company using the state-owned enterprise against payment – *Zakład Transportu Energetyki „ZTiSZE” Sp. z o.o.* – allocated all of the net profit for the payment of dividend in the last year of the research period. In period $t = 5$ the company – *Przedsiębiorstwo Robót Drogowych Sp. z o.o. Zaskórski i Wspólnicy* – paid the dividend which constituted 99% of the net profit of the given year.

In fifteen companies using state-owned enterprises against payment which generated positive financial results the arithmetic mean of the part of net profit allocated to the payment of dividend was between 2.55% and 30.11%. The arithmetic mean systematically increased apart from the fourth period after the year of privatisation. The highest value of the arithmetic mean of the part of net profit allocated to the payment of dividend was in period $t = 3$, when the difference of the value was the biggest. In the third period after the year of privatisation every second company allocated

Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

not more than 25.87% of the net profit in the given year to the payment of dividend (see table 2).

From the period $t = 1$ the company – *Polmos S.A.* – allocated all of the net profit to reserve capital after the payment of dividend. The company – *Biprodrzew S.A.* – allocated 8% of the net profit generated in a given year to supplementary capital as required by law (see Ustawa z dnia 15 września 2000 r., Article 396 §1).

In period $t = 0$ (the year of privatisation) seventeen companies using state-owned enterprises against payment allocated at least 80% of the net profit generated in a given year to supplementary capital. In the following two years after the year of privatisation fifteen companies allocated more than 80% of the net profit generated in a given year to supplementary capital. In each of the two years ten companies allocated more than 80% of the net profit to supplementary capital. After the period $t = 3$ eight companies using state-owned enterprises against payment allocated more than 80% of the net profit to supplementary capital.

Three companies using state-owned enterprises against payment – *Przedsiębiorstwo Robót Inżynieryjno-Drogowych Sp. z o.o. w Grójcu*, *Morspol S.A.* and *Bipromel Sp. z o.o.* – allocated all of the net profit to supplementary capital in each year of the research period.

In fifteen companies using state-owned enterprises against payment which generated positive financial results the arithmetic mean of the part of net profit allocated to supplementary capital was between 47.17% and 87.24%. The arithmetic mean successively decreased apart from the fourth period after the year of privatisation. The lowest value of the arithmetic mean of the part of net profit allocated to supplementary capital was in period $t = 3$, and the biggest difference of the value was in period $t = 2$. In the third period after the year of privatisation every second company allocated not more than 50% of the net profit in the given year to supplementary capital (see table 3).

After the payment of dividend and supplementary and/or reserve capital contribution, some companies using state-owned enterprises against payment allocated the remaining part of the net profit to the Company Social Benefits Fund (*Elmet Sp. z o.o.*) or to bonuses for management board members (*Biprodrzew S.A.*). Six of the surveyed companies covered losses from previous years from the net profit generated in a given year, including losses resulting from created provisions for employee benefits, i.e. retirement and pension benefits, jubilee bonuses (*Zakład Transportu Energetyki „ZTi-SZE” Sp. z o.o.*, *Zakład Transportu Energetyki Radom Sp. z o.o.*).

Conclusions

In the year of privatisation and in the period of two years after the year of privatisation every second company of fifteen surveyed companies using state-owned enterprise against payment did not pay dividends, transferring all of retained earnings to supplementary capital. The crucial factor determining net profit distribution in the surveyed companies was the will and/or the need to obtain exemption from the debt arising from deferral of additional fees. In the third period after the year of privatisation, which is after the period when the majority of companies using state-owned enterprises against payment was exempted from the debt arising from deferral of additional fees, every second surveyed company allocated not more than 25.87% of the net profit to the payment of dividend and not more than 50% of the net profit to supplementary capital. In the next two periods every second company using state-owned enterprise against payment did not pay dividends, transferring not more than 86% of the generated net profit to supplementary capital.

The average values of part of the net profit allocated to the payment of dividend and part of the net profit allocated to supplementary capital, characterized by opposite trends in the third period after the year of privatisation, had the greatest rate of change. In the period $t = 4$ the value of the arithmetic mean of the part of net profit allocated to the payment of dividend decreased to the level higher than in the period preceding the year $t = 3$, while value of the arithmetic mean of the part of net profit allocated to supplementary capital increased to the level lower than in the year $t = 3$.

Statistical Analysis of Business Cycle Fluctuations in Poland Before and After the Crisis*

JEL Classification: *C14; C46; E32*

Keywords: *APC processes; subsampling; Bayesian inference; global economic crisis; business cycle fluctuations*

Abstract: The main objective of the paper is to investigate properties of business cycles in Polish economy before and after the recent crisis. The essential issue addressed here is whether there exist statistical evidence that the recent crisis has affected the properties of the business cycle fluctuations. In order to improve robustness of the results we do not confine ourselves to any single inference method, but instead use different groups of statistical tools, including non-parametric methods based on subsampling and parametric Bayesian methods.

We examine monthly series of industrial production (from January 1995 till December 2014), considering properties of cycles in growth rates and in deviations from long-run trend. Empirical analysis is based on the sequence of expanding-window samples, with the shortest sample ending in December 2006. The main finding is that the two frequencies driving business cycle fluctuations in Poland correspond to cycles with periods of 2 and 3.5 years, and (perhaps surprisingly) the result holds both before and after the crisis. We therefore find no support for the claim that features (in particular frequencies) that characterize Polish business

cycle fluctuations have changed after the recent crisis. The conclusion is unanimously supported by various statistical methods that are used in the paper, however, it is based on the relative short series of the data currently available.

Introduction

The global financial crisis, with its origins occurred in August 2007, has addressed the need of a major rethink in macroeconomics, changing substantially directions of the frontier research. In particular, abrupt, strong and omnipresent effects of the crisis in the US subprime market affecting the global economic growth, prompted new studies on the nature of the procyclicality of the financial system, which has existed in macroeconomics through the decades as a topic of secondary importance; see Woodford (2003). Therefore the analysis of the empirical properties of the financial cycle is one of the most important issues of the empirical macroeconomics nowadays; see Borio et al. (2011), Borio (2014) and Drehman et al. (2012).

On the other hand, the aforementioned major rethink in macroeconomics not only traced new routes for researchers, but it showed some new perspectives of problems that has been studied for decades. Just before the crisis the empirical macroeconomics was focused on the observed correlation of changes of the world economic activity. Years preceding the crisis have seen new studies focused on construction of appropriate measures of synchronization of the business cycles rather, than examining well established properties of the cycle in the most of economies; see Stock and Watson (2005); Doyle and Faust (2005); Ayhan-Kose et al. (2003); Ayhan-Kose et al. (2008); Imbs (2004) and others.

The economic growth in the 1980s and 1990s has been remarkably more stable than the eight or nine decades that preceded it. Consequently, many researchers indicated that the properties of the business cycles changed distinctly, making fluctuations of economic activity relatively weaker at the beginning of the XXI century; see Taylor (1998), Romer (1999), Stock and Watson (2003) among others. In the mid-1980s, recessions in advanced economies rarely occurred and have become less pronounced, while expansion phases have become longer lasting; see Kannan et al. (2012). The literature explains this phenomenon by the globalization processes, the organizational and technical development observed in financial markets, changes in the structure of aggregate output, with growing importance of the service sector and still important but declining contribution of manufacturing to the growth, and – more importantly - better macroeconomic policies; see Blanchard and Simon (2001) and Romer (1999).

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

However the impact of the global financial crisis on the economy was definitely very strong. Hence the properties of the cyclical fluctuations in the real sector may have changed substantially. Also there is no doubt that all the explanations mentioned above for the hypothetical existence of the new era of stable economic growth that would have been initiated in 1980s, are no longer valid. Therefore the problem of renewed investigation of the empirical properties of the business cycle, especially for small open economies, is of importance nowadays. It is of crucial importance for the design of successful monetary policy. Moreover, Polish economy can be perceived as an interesting case, as it stayed resilient to the impact of the global financial crisis and seems to represent certain degree of balance between internal and external factors influencing business cycle.

The properties of business cycle in Polish economy were examined in: Skrzypczyński (2010), Gradzewicz et al. (2010), Adamowicz et al. (2008) and partially in Wośko (2009). Skrzypczyński (2010) used nonparametric band-pass filters and spectral methods; the author concludes that on a basis of Polish GDP data two lengths of business cycle were detected in the 1995 – 2007 period, namely a shorter business cycle with 3 years length and a longer one, lasting 6-7 years. The same set of tools was considered in Gradzewicz et al. (2010), but for a different set of macroeconomic data. The main conclusion formulated in the paper is that the length of the business cycle is approx. 6-8 years based on spectral analysis applied to all cyclical patterns extracted from the macroeconomic series under consideration. Only in the case of monthly industrial production index and monthly export, the business cycles with length 3-4 years were detected. Wośko (2009) considered a small set of general business indicators, and the main conclusion was that the length of business cycle is approx. 4 years. Adamowicz et al. (2008) considered a broad set of macroeconomic indicators, detecting the cycles within 2.5-4 years range. In summary, the authors have used different statistical methods, different datasets and obtained somewhat divergent conclusions.

The above overview suggest that the structure of the business cycle fluctuations in Polish economy is not fully transparent. Some of the authors focus on identification of a single most important pattern of cyclical fluctuations, whereas the observed dynamics could have been driven by different interfering components. This suggests that a potentially useful statistical method should allow for joint identification of several frequencies, and that the crucial issue is related to the uncertainty associated with statistical inference. The methods used in the literature vary with the respect to formal

advancement; some of the methods do not allow for testing significance or e.g. interval estimation of the cycle length.

The main objective of the paper is to investigate properties of business cycles in Polish economy before and after the recent crisis, using fully formal methods of statistical inference in order to shed some light on the discrepancies mentioned above. Since the last crisis in Poland was not as deep as in other European economies (Poland was called “the green island” on a red map) we suspect that formal statistical tools might indicate that the length of the business cycle have been relatively stable before and after the crisis.

Methodology of the research

We make use of two main groups of statistical methods here. In the first approach we rely on subsampling inference about discrete spectrum of the Almost Periodically Correlated (APC) stochastic processes; see Lenart (2013) and Lenart and Pipień (2013). The second approach bases on the Bayesian inference utilized for formal small sample statistical inference of frequencies (or equivalently, period lengths) in a parametric setup. We focus here on analysis of the parameters that are associated with the length of the cycle (or its frequency). Differences arising from amplitude or phase shift parameters are not of primary importance in the paper. Moreover, we compare the results with outcome of the method presented in Li and Song (2002).

We examine monthly series of industrial production index (covering period from beginning of 1995 till the end of 2014). We consider the series in levels and in growth rates (relating current month to analogous month of the previous year). The former is equivalent to analyzing a cycle of deviations, whereas the latter is equivalent to consideration of a growth cycle. The cycles are not perfectly equivalent, although it is possible to compare the resulting estimates for frequency (cycle length) parameters.

As for the first group of methods, the statistical analysis of the length of business cycle is based both on properties of APC time series and subsampling methodology. For observed real valued macroeconomic process $\{P_t; t \in Z\}$ with trend, seasonal and cyclical pattern, we build the concept on the basis on a univariate non parametric representation:

$$E(\tilde{P}_t) = f(t, \beta) + \sum_{\psi \in \Psi} m(\psi) e^{-i\psi t}$$

where $\tilde{P}_t = \ln(P_t)$ and $f(t, \beta)$ is a polynomial of order d , while $\sum_{\psi \in \Psi} m(\psi) e^{-i\psi t}$ is an almost periodic function (see Corduneanu (1989)), with unknown set of frequencies Ψ and corresponding Fourier coefficients $m(\cdot)$. The set of frequencies that corresponds to business cycle length that is greater than one and a half a year, is invariant after non-parametric differencing and $(2 \times T)$ MA filters, where T is the number of observations during a year (see Lenart and Pipień (2013)). Since $\psi \in \Psi \Leftrightarrow m(\psi) \neq 0$, the problem of testing significance of frequency ψ (in the sense that $\psi \in \Psi$) is equivalent to testing the significance of a Fourier coefficient $m(\psi)$ (in the sense that $m(\psi) \neq 0$). It is important to emphasize that the methodology is not based on the filtering methods, which is a distinctive feature of the approach. In order to test the significance of Fourier coefficients, the subsampling (see Politis et al. (1999)) is applied since the asymptotic distribution of the test statistics is too complicated to be used in practice. For more details, see Lenart and Pipień (2013).

As for the second group of the methods, for the sake of parametric analysis we assume the following structure of the time series under consideration:

$$R_t = \mu_t + v_t$$

where R_t represents y-o-y growth rates, with v_t corresponding to a stationary Gaussian autoregressive process of order p , and

$$\mu_t = \sum_{f=1}^F (\alpha_{1,f} \sin(t\phi_f) + \alpha_{2,f} \cos(t\phi_f)).$$

Parameters $\phi_f \in (\phi_L, \phi_U) \subseteq (0, \pi)$ represent frequencies of the fluctuations, whereas $\alpha_{1,f}$ and $\alpha_{2,f}$ represent amplitudes and phase shifts. With F being estimated rather than set known *a priori*, the structure of the dynamics can be modeled in a flexible way, allowing for the existence of several significant components in the overall dynamic pattern. Estimates of F can be obtained by conducting a fully formal model comparison.

Bayesian estimation of the above model requires specification of the prior densities for the parameters under consideration. We make use of the proper priors, in particular the frequency parameters (that are crucial in the analysis to follow) are assumed to be *a priori* uniformly distributed on (ϕ_L, ϕ_U) . The lower and upper boundary values ϕ_L and ϕ_U are fixed so that cycles shorter than one year and longer than 10 years are *a priori* ruled out. The idea of excluding longer cycles is related to the fact that the time series available for Polish economy are not really long, making the inference on very low frequency features very problematic. Moreover, based on posterior results for ϕ_f it is possible to induce the equivalent posterior for cycle length, which takes into account the uncertainty associated with identification of the cycle length. The resulting marginal posterior can be irregular (in particular multimodal), most likely suggesting that $F > 1$.

It must be highlighted that the crucial feature of the methods outlined above is the formal way of dealing with inferential uncertainty. Significant frequencies (or cycle lengths) can be identified based on formal tests (for subsampling approach) or e.g. highest posterior density (HPD) intervals (for the Bayesian approach). It is therefore possible to avoid *ad hoc* decisions based on point estimates only.

In order to illustrate properties of the methods used here relative to some other approaches used in the literature, we consider also the results obtained using a procedure proposed by Li and Song (2012). This method is called contraction mapping method (CM in short) and assumes that univariate time series $\{X_t; t \in Z\}$ is given by:

$$X_t = \sum_{k=1}^r \beta_k \cos(\omega_k t + \vartheta_k) + \varepsilon_t,$$

where $\{\varepsilon_t; t \in Z\}$ corresponds to stationary time series with zero mean. The objective of the method is to estimate the unknown frequency. Notice that the mean function of the time series $\{X_t; t \in Z\}$ is almost periodic. For details concerning the estimation procedure see Li and Song (2002).

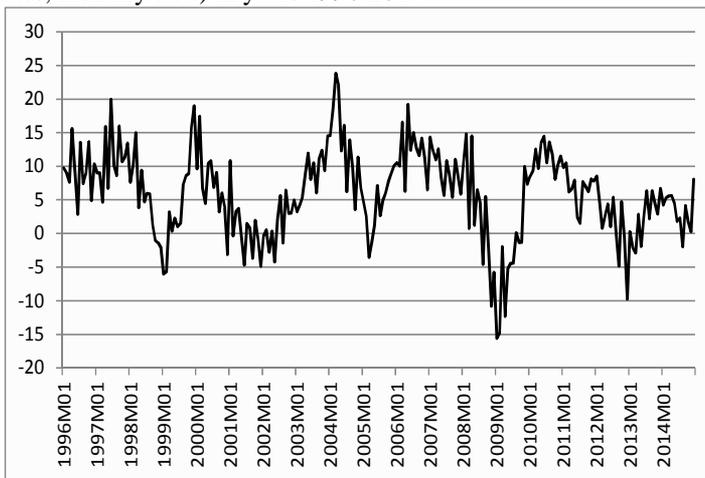

Empirical results

In order to evaluate potential influence of the recent crisis on business cycle pattern, the empirical analysis to follow is based on the sequence of expanding-window samples, with the shortest sample ending in December 2006, and the longest one ending in December 2014. In order to maintain

coherence, for the methods based on levels, the initial observation is January 1995, whereas for the growth rates it is January 1996.

The empirical results presented in the paper are founded on analysis of the time series of the industrial production index. The idea is to choose the crucial dataset and use a whole menu of various statistical methods instead of applying simple methods to a broad set of series, which makes formal pooling of the results difficult. The dataset used here is depicted in Fig. 1.

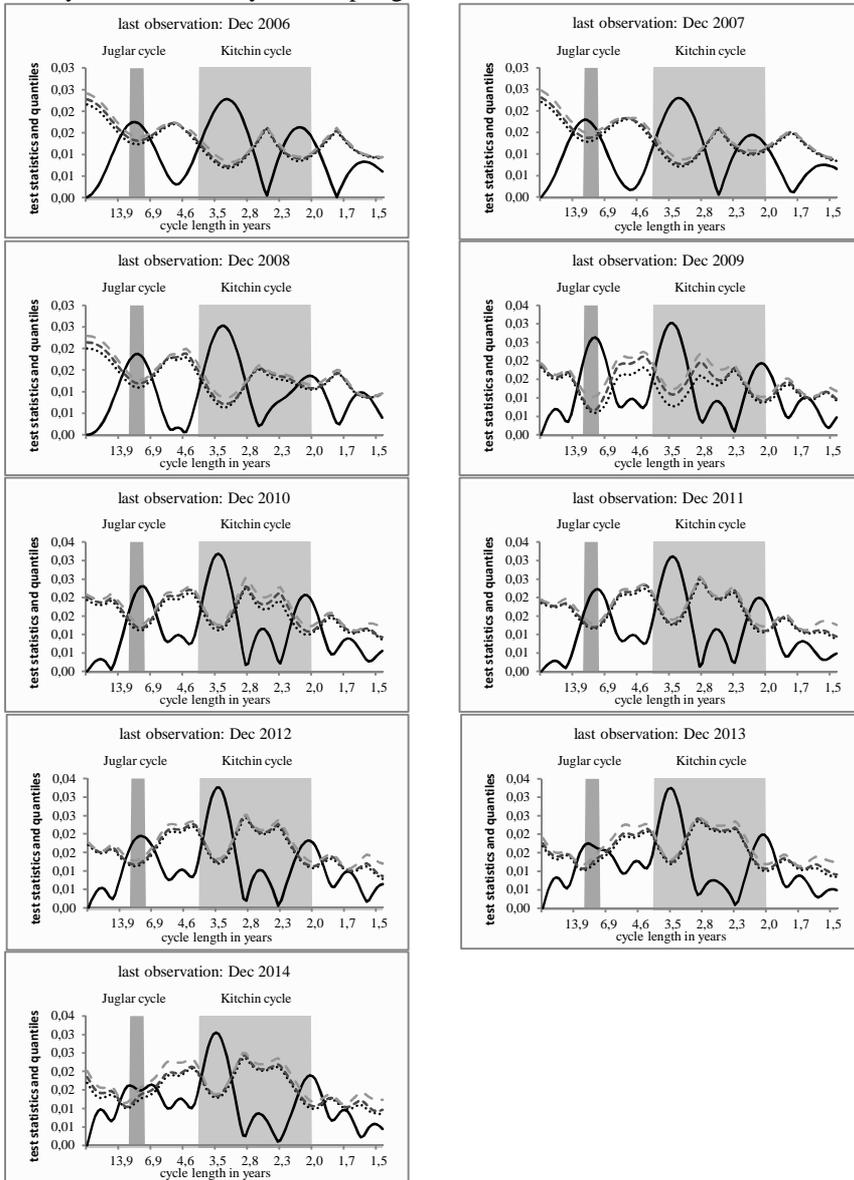

Figure 7. Dynamics of the industrial production index in Poland (y-o-y percentage growth rates, monthly data) in years 1996-2014

Source: Eurostat

Recursive analysis based on the subsampling approach applied to the data in log-levels (which amounts to analysis of the deviations cycle) revealed the results depicted in Fig. 2.

Figure 8. Polish industrial production index – significant frequencies of the deviations cycle uncovered by subsampling test.

Source: own calculations.

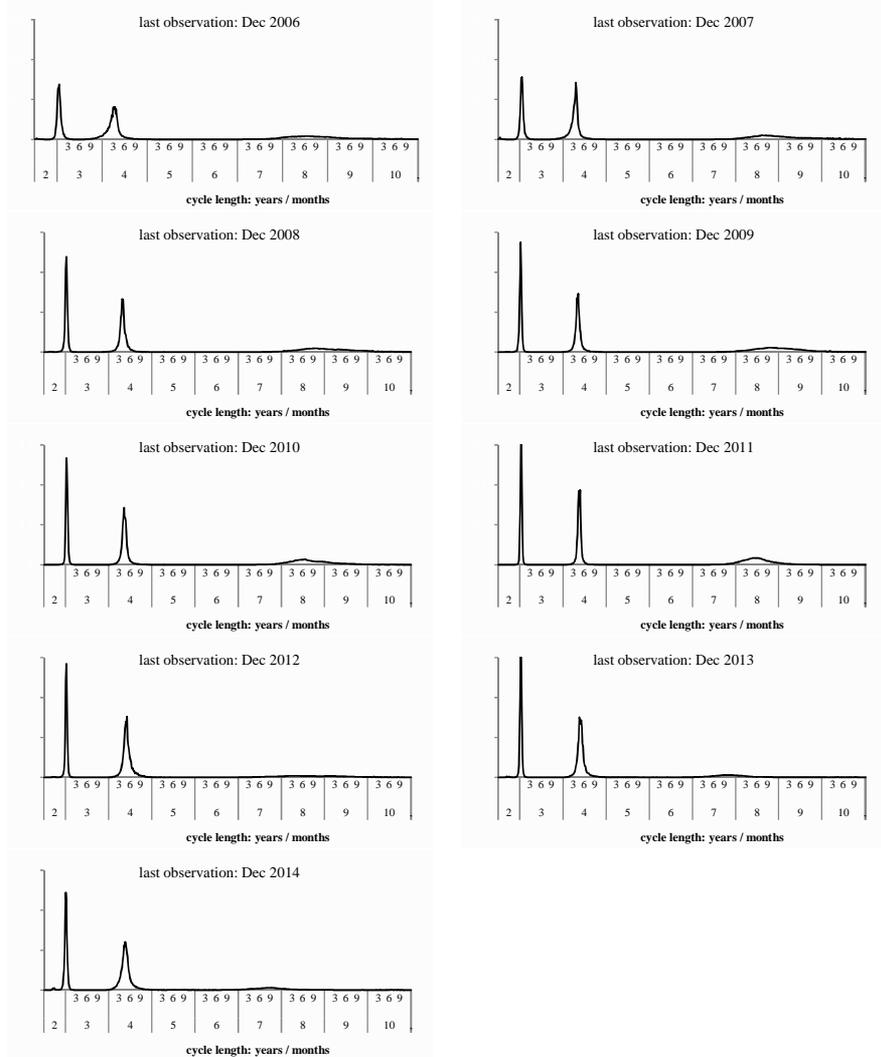

The above figure presents the test statistics for significance of $|m(\psi)|$ with subsampling quantiles at nominal levels of 0.08, 0.05 and 0.02. Solid lines in each panel correspond to values of the test statistics, with critical values represented by dotted lines. Values on the horizontal axes are associated with cycle length in years. Significant frequencies (cycle lengths) correspond to test statistics values exceeding critical values. Analysis of Fig. 2 suggests existence of three components in the dynamics of Polish industrial production data, and the highest values of the test statistics (relative to the critical values) characterizes the cycle of approx. 3.5 years. The two remaining significant frequencies correspond to cycle lengths of about 2 years and approximately 8-10 years (with quite considerable uncertainty in the latter case). The results seems to be fairly stable along with recursive expansion of the sample. One can also see that the uncertainty as for the cycle length seems higher for shorter samples, which is quite intuitive.

Results of the Bayesian parametric approach applied to the industrial production index transformed to growth rates are depicted in Fig. 3. The solid line represents probability density function of the marginal posterior distribution for the duration parameter, obtained as one-to-one transformation of the frequency parameter ϕ_f , obtained by assuming $F = 3$. The distribution has three modes, indicating existence of three different cycles. Again, there are cycles with period length of 2 years and about 3.5 years. The two-year cycle seems to be estimated very precisely in terms of length, which is also very stable over time. The second component associated with the cycle of almost 3.5 years shows more uncertainty and some instability. However, it is very moderate and as the uncertainty is taken account, the instability is by no means significant.

The analysis suggests the existence of the third component corresponding to the cycle of approx. 8 years. However, the probability mass related to the component is dispersed and it is difficult to derive decisive conclusions other than that there is visible instability in its estimates, though it is coupled with quite large dispersion. There is also a difference between the results from the non-parametric approach (Fig.2) and the results from the Bayesian approach (Fig. 3) with respect to the properties of the longest cycle. The changes in its estimated cycle length (arising from recursive expansion of the sample) in the two approaches seem to follow the opposite direction. However, the differences seem not to be significant.

On the overall, the results of the Bayesian approach within the growth cycle setup seem quite coherent with the results obtained by subsampling methods with respect to the deviations cycle.

Figure 9. Polish industrial production index - Bayesian marginal posterior for growth cycle length induced by posterior distribution of the frequency parameter.

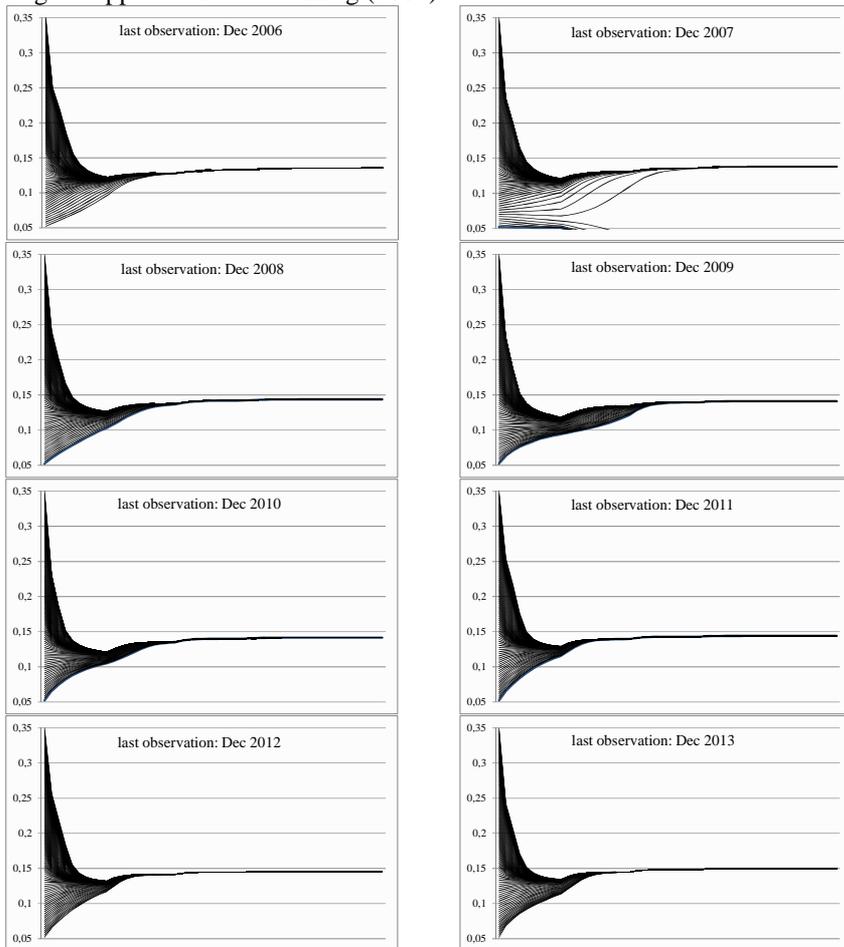

Source: own calculations.

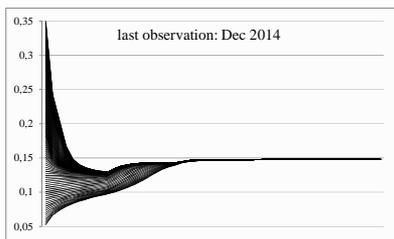

However, in order to provide a comparison to other methods used in the literature, Fig. 4 depicts the outcome obtained using the parametric procedure proposed by Li and Song (2002). CM frequency estimates ranging from 0.05 to 0.35 are depicted on vertical axes, with increasing number of

iterations on horizontal axes. The number of iteration is equal to 50. The bandwidth parameters are the same as in Lenart (2013): $\eta_1 = 0.98$ for $m \leq 8$, $\eta_2 = 0.99$ for $9 \leq m \leq 16$, and $\eta_3 = 0.995$ for $m \geq 17$.

Figure 10. Analysis of the Polish industrial production index (y-o-y growth rates) using the approach of Li and Song (2002)

Source: own calculations.

Each frequency ψ corresponds to the cycle length of $2\pi/\psi$. Therefore for the monthly data the set of frequencies (0.05;0.35) corresponds to the length of the cycle between one and a half year and ten years. The results indicate that, contrary to the approaches used in the paper, the method of Li and Song fails to detect different periodic components that seem to be present in the Polish industrial production data. The results also reinforce the importance of the cycle of almost 3.5 years (which is associated with values of frequency parameter close to 0.15).

Summary of the point estimates of cycle lengths obtained by the non-parametric subsampling-based approach and the parametric Bayesian approach is depicted in Fig. 5. Since the non-parametric method is not computationally time-consuming, its results are updated every six months.

Figure 11. Significant cycle lengths – comparison of the results from non-parametric and parametric Bayesian approach.

Source: own calculations.

The results summarized in Fig. 5 show that Bayesian parametric method applied to growth cycle and non-parametric method used to investigate cycles in deviations from trend lead to very similar inference regarding cycles with period length of 2 and 3.5 years. As the uncertainty is taken into account, the results do not support the claim of significant changes in the business cycle pattern in Polish economy after the crisis. The results associated with longer cycles (with period of 7-10 years) are somewhat less clear. The estimates are less stable here, the uncertainty is greater and sub-sampling-based approach reveals systematically longer cycles, as compared to the Bayesian approach. Again, the instability in point estimates is small relative to the uncertainty.

Conclusions

The main objective of the paper is to investigate properties of business cycles in Polish economy before and after the recent crisis. The essential issue addressed here is whether formal methods of statistical inference provide evidence supporting the view that the recent crisis has changed the properties of the business cycle fluctuations. It is of particular interest whether considering the data representing also the after-crisis period leads to differences as for inference on crucial frequencies describing the dynamics of Polish economy.

In order to improve robustness of the results we do not confine ourselves to any single inference method, but instead use two different groups of statistical tools. As for the first group, these are non-parametric methods that rely on subsampling. The second group includes Bayesian methods employed within the parametric approach. However, all the methods used here use allow for formal quantification of uncertainty and co-existence of cycles with different periods, which is a crucial feature of our analysis. Within the non-parametric approach, a formal test is used to detect significant frequencies. Within the Bayesian approach, the uncertainty is fully described by (multimodal) posterior distribution of frequencies (or equivalently, period lengths), so the inference is fully formal.

We examine monthly series of industrial production index (covering period from beginning of 1995 till the end of 2014), taking into account levels (for deviations cycle) and growth rates (for growth cycle). Empirical analysis is based on the sequence of expanding-window samples, with the shortest sample ending in 2006. The main finding of the paper is that the two most important frequencies driving business cycle fluctuations in Poland

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

correspond to cycles with periods of 2 and almost 3.5 years, and (perhaps surprisingly) the result holds before and after the crisis. Results regarding the cycles with period length of 7-10 years are less stable, but do not support significant change after the crisis either.

We therefore find no support for the claim that cycle length that characterize Polish business cycle fluctuations was affected by the crisis. The conclusion is unanimously supported by various statistical methods that are used in the paper (given the cut-off date being the end of 2014). However, we do not consider potential changes in phase shift or amplitude of the fluctuations. It is therefore possible that with more post-crisis observations some evidence for influence of the crisis would eventually be uncovered.

**Trends in IPOs: The Evidence from CEE
Capital Markets¹**

JEL Classification: *E44; G23; G32*

Keywords: *IPO; Going Public; Trends; Financial Markets; CEE*

Abstract: The purpose of this paper is to investigate IPO developments across five CEE countries between 2003 and 2012. Using a wider range of methods and different data sets we intend to complement the previous research. Applying descriptive statistics, relevant local developments are analysed first before being compared with leading European markets (London Stock Exchange and Deutsche Börse). We also investigated the assumption that a growing market has an explanatory power for the accelerating IPO activity. For this purpose we performed a Spearman correlation analysis. The data were evaluated at the significance level of $\alpha = 5\%$. All CEE capital markets recorded strong dynamism over the observed period. All fundamental capital market parameters increase the attractiveness of individual capital markets, although their values lag behind developed European capital countries. The unambiguous leader in the region is Poland with a flourishing IPO market. Our assumption that a growing market has a positive impact on IPO activities could not be supported by empirical evidence.

¹ The research is financed by Internal Grant Agency of the Brno University of Technology. Name of the Project: Economic Determinants of Competitiveness of Enterprises in Central and Eastern Europe. Project Registration No. FP-S-15-2825.

Introduction

Substantial academic literature devotes a significant amount of research to emphasising the importance of the financial system to economic growth. Kominek (2003) summarises recent empirical research (e.g. Schumpeter, 1911; Robinson, 1952; Lucas, 1988; Demirguc-Kunt & Maksimovic, 1996; Levine & Zervos, 1998; Rajan & Zingales, 1998) and concludes that “well developed financial systems stimulate economic growth”. Although the continental financial system is traditionally focused on banking, there is increasing interest in the stock markets and initial public offering (IPO) implementation (e.g. Pagano et al., 1998; Black and Gilson, 1998; Chemmanur & Fulghieri, 1999; Ritter & Welch, 2002).

According to existing definitions an IPO refers to the fact that a company offers its securities, in the strict sense of the word shares, to the public for the first time, and also enters the public organised securities market, represented most frequently by its stock exchange. The essential thing is that an IPO can only be used by issuers whose securities are not being traded on the public securities market at that time (Jenkinson & Ljungqvist, 2001; Huyghebaert & Van Hulle, 2006). According to the origin of the shares offered in an IPO, these authors distinguish between an IPO of primary shares, with the issuing of new shares and their placement on the public primary securities market, and an IPO of secondary shares, consisting of offering previously issued shares that have been traded only on the private secondary securities market.

The IPO markets of Central and Eastern Europe (CEE) have been empirically investigated by a relatively small number of academic studies. Peterle (2013) argues that, “apart from statistical data, there is almost no available academic research of IPO characteristics covering the entire CEE region, especially in the 2000s”. She studied IPOs between 2000 and 2009 and concludes that capital market factors such as “market size, liquidity and market capitalisation to GDP do not have a decisive impact on IPO activities in the CEE region”. On the other hand, “the attractiveness of the capital market as measured by annual stock index returns and by annual market and liquidity growth” may have been an incentive for decision-makers about IPOs in the observed period. Findings by Brzeszczynski (2014) show that “decisions about IPOs in Poland are strictly dependent on stock market phases and that IPOs tend to increase when share prices are rising and to decrease when they fall. This relationship is not simultaneous, as some lag

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

effect can be observed that may be linked to the length of time taken by decision-makers”.

Institutional and historical (i.e. qualitative) factors have been assessed by “soft” indicators such as perception of the capital market by enterprises, their confidence in the capital market and the quality of national regulations and structures. Roženský (2008) explored conditions created by local CEE stock exchanges using the following indicators: cost of going public, administrative requirements of issuers, the market segmentation of the particular stock exchange and, finally, its marketing and public relations. Groh, Lichtenstein & Lieser (2010) calculated composite indices to compare the attractiveness of 27 European countries for institutional investments in venture capital and private equity. They conclude that “the investor protection and corporate governance rules and the size and liquidity of its capital market are likewise a proxy for the professionalism of the financial community, for deal flow and exit opportunities”.

Using a wider range of methods and different data sets we intend to complement the previous research (Roženský, 2008; Peterle, 2013; Brzeszczynski, 2014) by considering IPO developments across five CEE countries between 2003 and 2012. Applying descriptive statistics, relevant local developments are analysed first before being compared with leading European markets.

Methodology of the Research

We investigated five CEE capital markets – Poland, the Czech Republic, Hungary, Slovenia and Austria. Apart from Austria, all these countries share a similar historical background after World War II. All these countries turned to communism, built-up centrally planned economies and applied shock therapies in the early 1990s after the disintegration of the communist economic alliance. They all undertook different privatisation programmes during the first years of transition and a “prime example of this difference in attitudes is given by the organisation and development of the Czech and Polish stock exchanges” (Kominěk, 2003).

The nature of this study is based on the theory and previous empirical research. All IPO indicators analysed in this paper have sufficient support in the financial academic literature (Roženský, 2008; Groh, Lichtenstein & Lieser, 2010; Peterle, 2013; Brzeszczynski, 2014).

The quantitative analyses of CEE IPO developments are based on evidence over the period from 2003 to 2012. Our sample includes enterprises

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

that conducted an IPO on the Main Markets of CEE Stock Exchanges. Both the IPO and capital market data were obtained predominantly from Stock Exchange Fact Books, the Federation of European Securities Exchanges (FESE), the World Federation of Exchanges (WFE) and PwC (IPO Watch Europe).

The following steps were undertaken to analyse the quantitative data. Firstly, we performed a descriptive analysis in order to draw attention to certain specific issues existing on CEE IPO markets between 2003 and 2012. Next, we compared internal IPO characteristics on CEE markets with the empirical evidence on IPOs on the most developed EU capital markets (London SE and Deutsche Börse). We also investigated the assumption that a growing market has an explanatory power for the accelerating IPO activity. For this purpose we performed a Spearman correlation analysis. The data were evaluated at the significance level of $\alpha = 5\%$. The entire statistical evaluation was performed by Statistica.CZ, Version 9. Descriptions of variables and the sources of data used are shown in Table 1. The results are explained and discussed with the conclusions of previous studies conducted under the conditions in force on developed capital markets.

Empirical Results

Equity Market Capitalisation

In terms of size, the Warsaw Stock Exchange was dominant in the CEE region, holding a 39 % share of market capitalisation, followed by the Vienna Stock Exchange with a 36 % share of market capitalisation. The form and timing of privatisation fundamentally influenced market capitalisation in the 1990s. Roženský (2008) concludes that it was a positive influence in the Czech Republic and Hungary, though a negative influence in Poland because of the different manner of privatisation. In the second decade after the establishment of the local capital markets, more precisely between 2003 and 2012, the market capitalisation (in EUR) increased 2.5 times on the CEE market as a whole (see Table 2). The growth of the market was faster in comparison with established capital markets such as London, where market capitalisation increased by a factor of 1.5, or Frankfurt, where market capitalisation increased by a factor of 1.4. However, significant discrepancies can be observed in the development of individual markets (market capitalisation increased by a factor of 4.6 in Warsaw, 2.3 in Prague, 1.19 in Hungary, 0.87 in Slovenia and 1.79 in Austria). Since joining the EU (2004; Austria has been a member of the EU since 1995), all CEE capital markets amounted to 409,819 million EUR in the peak year of 2007 which represents only 16 % of the market capitalisation of the London Stock Exchange and 28 % of the market capitalisation of the Deutsche Börse. When we compare the CEE capital markets with developed capital markets in Western Europe, it must be noted that these markets are significantly smaller. Furthermore, in 2008, at the height of the financial and economic crisis, the decline recorded on this market was greater (–57 %) than on developed capital markets (UK –49 %, Germany –45 %). Changes in the value of market capitalisation were affected by three main factors – the financial and economic crisis of 2008, the appreciation/depreciation of local currencies, and the privatisation programme implemented by Polish governments (see also Roženský, 2008).

Index Returns

Assuming that a faster growing market promises higher subscription prices, it can be said that potential issuers will tend to go public on markets with higher rates of return. Differences in index returns can, for this reason, be essential during decision-making concerning IPOs. Spectacular annual index rate returns were recorded on all CEE stock capital markets during 2003–2012 and the Vienna, Budapest, Warsaw and Prague SEs in particular revealed significant potential for both investors and issuers (Table 3).

CEE IPO Developments

Table 4 gives an overview of market statistics of annual IPO time series. A total of 390 IPOs were listed during the period 2003–2012 on the EU-regulated CEE primary capital markets which represents a 25.34 % share of the whole EU-regulated market. The sum of the capital raised by the issuing companies was EUR 30,380 million, i.e. 11.22 % of the new money raised through IPOs in Europe. The average IPO size was EUR 77.89 million and therefore amounted to 44.28 % of the average in Europe as a whole. Prior to the financial and economic crisis (2008–2009), there was a remarkable boom in the annual number of IPOs which increased from 12 in

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

2003 to 90 in 2007. The sharp decline in the number of IPOs in 2008 and 2009 was followed by a slight recovery of the market between 2010 and 2012.

Table 4. CEE IPO market statistics and a comparison with the EU-regulated markets, 2003–2012

Source: CEE Stock Exchange Group and its Capital Markets; Warsaw Stock Exchange, Fact Books (2003–2013); PWC – IPO Watch Europe (2003–2013); Federation of European Securities Exchanges, Statistics & Market Research; World Federation of Exchanges, Statistics; Peterle (2013); Roženský (2008); Sieradzki (2013); own calculations.

Table 4 further shows the market capitalisation of CEE stock exchanges over the last ten years. The sum of market capitalisation is EUR 2,502,138 million which is still a significantly small value in comparison with the leading European markets. The market capitalisation of the CEE primary capital markets amounted to 25 % of the Deutsche Börse market capitalisation and only 11 % of the London Stock Exchange market capitalisation.

Warsaw's share of the EU-regulated market by number of issues increased to 21 % in 2012 from 9 % in 2003. This placed the Polish IPO market among the most active primary markets in Europe. On the other hand, the IPO market share by offering value experienced significant growth only between 2008 and 2010. The 8 % average share of offering value on the EU-regulated market, despite a 12 percentage points average increase in the number of IPOs, reflects the number of relatively low-value IPOs Warsaw hosted on its Main Market.

Table 7 shows the degree to which national governments have used the capital market as a tool of privatisation over the last ten years. Privatisation via IPOs (PIPOs) was executed on four CEE capital markets. WSE continued to dominate the number of privatisation IPOs on the CEE market (20 cases of privatisation) followed by Austria (5 cases of privatisation), Hungary and Slovenia (1 case of privatisation on each market). Private IPO levels in the region were more than 93 % in terms of numbers between 2002 and 2012.

In view of its extraordinary importance among the CEE capital markets, we also focused on IPO types conducted on the Warsaw SE. Table 8 presents their distribution based on the proportion of primary (new) and secondary shares in IPOs. We can therefore conclude that IPOs with only primary stocks in Poland prevailed with a share higher than 50 %, however

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

this share was 20 percentage points lower than indicated for continental Europe (Kim and Weisbach, 2006).

Conclusions

Our results indicate strong dynamism on all CEE capital markets between 2003 and 2012. The growth of these markets evaluated by market capitalisation was significantly faster in comparison with developed capital markets in Western Europe, especially before 2008. First and foremost, Poland outperformed all other countries and replaced the former local leader, Austria.

When we consider annual stock index returns, the favourable development of these indicators is another sign of the dynamism recorded on CEE stock exchanges. This could be seen as a signal of increasing market attractiveness for both investors and potential issuers (IPO candidates) and thereby accelerate IPO activity. High average values of annual stock index returns on all CEE stock capital markets were outstanding in comparison with the developed capital markets and were, therefore, another factor increasing CEE capital market attractiveness.

However, despite the promising development of fundamental capital market parameters, our evidence supports the conclusions made by Peterle (2013) that all CEE capital markets, including the Warsaw SE, are characterised by their “lower quality” as compared with developed EU markets. Using Spearman correlation analysis we tested our assumption that a growing market has an explanatory power for the accelerating IPO activity, particularly in Poland. This assumption could not be supported by empirical evidence which implies that although IPO activity was increasing, especially before 2008, no relationship could be identified between the increasing number of primary issues and indicators of size on capital markets. This confirms the findings of Peterle (2013), namely that “capital market factors do not have a decisive impact on IPO activities in the CEE region”, although certain capital market parameters reflecting increasing capital market attractiveness could be an important IPO accelerator. Roženský (2008) concluded, on the basis of descriptive statistics for the CEE capital markets between 2003 and 2008, that the contribution of primary emissions to market capitalisation growth cannot be considered essential in view of the small value of new issues and their low performance: “Increasing market capitalisation on the Budapest, Warsaw and Prague SEs is more related to stock index returns”. Roženský (2008) also points out the low liquidity of the stock of new listed companies in Poland between 2003 and 2007: “Only few new listed companies contributed significantly to market turnover.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

Moreover, these companies were either privatised or parallel listed by their foreign shareholders.”

To sum up our conclusions, all CEE capital markets recorded strong dynamism over the observed period. All fundamental capital market parameters increase the attractiveness of individual capital markets, although their values lag behind developed European capital countries. The unambiguous leader in the region is Poland with a flourishing IPO market. Our assumption that a growing market has a positive impact on IPO activities could not be supported by empirical evidence.

A further research on the issues addressed in this paper assumes, firstly, a modification of the explored variables (a combination of macroeconomic, institutional and capital market factors), secondly, an analysis of the individual markets based on both quantitative and qualitative models, and finally a continuous extension of the time series.

**The Cost of Capital in the Effectiveness
Assessment of Financial Management
in a Company**

JEL Classification: *G32*

Keywords: *capital; cost of capital; value pricing*

Abstract: Financial management in a company is a decision process subject to achievement of the main goal of the company, that is its value maximization. Estimation of the cost of capital is of great significance in this area. The cost of capital affects the key decisions of the board concerning the scale of investment undertakings, determination of the target, demanded amount and pace of capital growth, shaping of optimal capital structure and other areas of financial management in a company such as capital budgeting, processes of takeovers and fusions etc. It is also a parameter in calculating the return on investment and in other analyses. The utilization of information about the cost of capital in the decision-making process in the company is strictly connected with the assessment of financial management in the company using market value added. The objective of the article is to review the theory confirming the thesis that the effectiveness assessment of financial management in the company, in the context of market value added growth, is largely dependent on the cost of capital in the company. The article is of theoretical-cognitive and methodological character. It constitutes a reason for further empirical research confirming the relation proved in the theory between the cost of capital and company value, which is a basis for the effectiveness assessment of financial management in the company.

Introduction

Financial management in a company is a decision process subject to the achievement of the main goal of the company, that is value maximization. Awareness of the company value has great significance in the business activity of each company and constitutes the most important criterion of making decisions by the owners and executives. In theory and practice a view is common about the key significance of the cost of capital in shaping the company value. It is one of the basic and still discussed issues raised in the field of corporate financial management (Caputa, 2010, pp. 88-100). The purpose of the article is a review of theory confirming the thesis that the effectiveness assessment of financial management in the company is largely dependent on the cost of capital in the company. The subject of the research are the considerations of F. Modigliani and M. Miller as they are the first model solutions related to the problem raised. The author also related to other models created on the basis of these considerations, which may be an alternative. The article is of theoretical-cognitive and methodological character and constitutes a reason for further empirical research that confirms the relation proved in theory between the cost of capital and company value, being an effect of the activities undertaken within the frames of corporate financial management. In the research conducted a method of literature studies was used, both a domestic and foreign one.

The outline of the problem of the cost of capital evaluation

In the considerations concerning the company value it is very important to define the cost of capital precisely. The cost of capital is generally defined as the expected return rate by the investors (both owners and creditors) on the invested capital at the particular risk level. It is connected with the alternative cost, that is the expected return rate on investment that the investors resign from when they choose a particular type of activity and resign at the same time from other possibilities available in a given moment (Compare Duliniec, 2001, p. 149; Kerins at al., 2004, pp. 385-405).

Estimation of the cost of capital is connected with a division of capital into debt capital and equity and consists in a separate calculation of the alternative cost for the particular financing sources of debt capital and equity as well as in calculation, on their bases, the weighted average cost of capital in which target capital structure determines the weights of the separate components (Jonek-Kowalska, 2011, pp. 117-136).

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

Equity is the company owner's or owners' contribution. In the moment of company establishment it constitutes a sum of resources (assets) brought in by the owner (owners). In the course of conducting the business activity it will be increased by the value of profits achieved. Debt capital is a capital left at the company's disposal for a definite period of time and after that it must be returned. A further division of debt capital may be made into a long-term one that includes long-term credits and bonds, long-term bank loans and other long-term liabilities that will be paid off after over 1 year and into short-term debt capital that comprises of credits, bonds, bank loans and other trade payables as well tax and remuneration liabilities due in less than one year.

In order to determine the weighted average cost of capital there should be the cost of capital calculated coming from different sources engaged in business financing, e.g. the cost of shareholder capital, the cost of bank loans, the cost of capital obtained from bonds sales etc. (Che & Sethi, 2014, pp. 1-34). Each element of capital is subject to different pricing depending on the way of determining the benefits for the capital provider, tax solutions etc. Next, the costs of capital are "weighted" by the share of the particular sources in the capital structure. In a general form, weighted average cost of capital (WACC) may be expressed by the following formula (Groth & Anderson, 1997, p. 477; Jajuga & Słoński, 1997, p.149; Brigham, & Gapenski, 2000, p. 238):

where:

$$WACC = \sum_{i=1}^n w_i K_i$$

where:

w_i – i-number of the sources of capital,

K_i – cost of capital coming from the source of i-number,

n – number of capital sources.

This formula is also presented in a more general form that includes the cost of equity that is obtained from common and preferred stock issuance as well as the cost of debt capital:

$$WACC = w_d k_d (1-T) + w_p k_p + w_e k_e,$$

where:

w_d – debt capital,

w_p – capital from preferred stock issuance,

w_e – capital from common stock issuance,

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

k_d – cost of debt capital,
 k_p – cost of capital from preferred stock,
 k_e – cost of equity from common stock.

The return rate on the particular types of capital is the required return rate on the capital invested by the owners and creditors, determined using market criteria. Beside the return rate, the weighted average cost of capital in the company depends on the capital structure shaped in the company (Ickiewicz, 2001, p. 208).

Determination of the capital structure for the purpose of the cost of capital estimation is connected with some problems. They are connected with various ways of defining the capital structure in the company. The notions of capital structure, liabilities structure and financing sources structure are interchangeably used. These are not fully identical notions though. Defining the capital structure is grounded on the basic division of capital into equity and debt capital as well as on a long-term and short-term capital. One of the depictions of capital structure is its perception as the share of debt capital and equity in financing the company's activity (Sierpińska & Jachna, 2003, p. 255; Bień, 1998, p. 174; Turek & Jonek-Kowalska, 2009, pp. 16-20; Janasz, 2010, p. 35; Jerzemowska, 2006, p. 155; Gabrusewicz, 2005, p. 115). However, there is another approach possible that debt/equity relation determines the structure of company's financing, furthermore, the capital structure is a relation of long-term debt and equity (Moyer et al., 1992, p. 518; Weston & Copeland, 1992, p. 493). Consequently, the capital structure is a part of financing structure which, beside long-term debt and equity, also takes short-term debt into account (Petty et al., 1993, p. 354). Such approach is similar to the considerations of F. Modigliani and M. Miller concerning the relation of debt and equity in the company. According to them, the most common feature of debt as an element of capital structure is payment of interest on debt incurred.

**Effectiveness measurement of corporate financial management
in the view of company value – model solutions**

Corporate financial management should be subject to the achievement of the main goal of the enterprise, that is value maximization and in the view of this category, the effectiveness of management should be assessed. At the same time one should pay attention to a special role of the cost of capital in the process of company value pricing and in the process of effectiveness assessment of corporate financial management too. The relation of

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

company value and the cost of capital was visibly emphasized in the theory of two Noble Prize winners - F. Modigliani and M. Miller (1958), who in 1958 published the article „*The Cost of Capital, Corporate Finance and the Theory of Investment*”. They proposed the first model solutions in this area, determined as MM models from their initials. They based their research on the following assumptions:

- each company may be classified to the groups of different risk level (risk class). The companies from the same groups are burdened with the same level of operational risk, measured as standard deviation of return on equity,
- transactional costs of securities issuance or turnover are not included in the analysis, the securities are freely divided and the information about the capital market is commonly accessible and free of charge,
- there are no taxes,
- companies do not go bankrupt, therefore the interest on capital is the same for everyone as the interest rate on the capital market is free of risk.

On the basis of such assumptions made, two theorems were formulated called MM model without taxes. Proposition I states that the company value does not depend on the capital structure and the weighted average cost of capital (WACC) does not depend on the amount of debt and is equal to the cost of equity of the company that does not use debt capital and it is in the same risk class. In this case the company value is determined using the following formula (Pluta, 2000, p. 120):

$$V_U = V_L = \text{EBIT} / \text{WACC} = \text{EBIT} / k_{eU},$$

where:

- V_U – value of unlevered company,
- V_L – value of levered company,
- k_{eU} – cost of equity of unlevered company,
- EBIT- earnings before deducting interest and taxes,
- WACC – weighted average cost of capital.

The second theorem of MM model without taxes relates to the mathematical dependence between changes in the cost of equity and depending on the degree of financing by debt capital in the company. The formula describing Proposition II of MM model is as follows:

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

$$k_{eL} = k_{eU} + (k_{eU} - k_d) (D/E),$$

where:

k_{eL} – cost of equity of levered company,

k_d – cost of debt,

D – market value of debt,

E – market value of equity.

According to the above, the benefits achieved thanks to using a cheaper debt capital (k_d) are levelled by the increase in the cost of equity (k_e). Consequently, obtaining debt capital by the company affects neither the value of weighted average cost of capital nor the company value.

After introducing income tax to MM model the value of the company using debt capital exceeds the value of the company financed by equity only. The difference is the value of so called tax shield, also called deferred tax (DT). It is the value of tax savings connected with deducting the interest on debt from the tax base. This dependence may be showed as (Proposition I):

$$V_L = V_U + DT.$$

The value of unlevered company (V_U) results from the following formula:

$$V_U = E = EBIT(1-T)/k_{eU}.$$

According to the above, the company may increase its value by increasing the share of debt capital which may, in theory, eliminate equity from the capital structure, but then the issue of risk arises.

Proposition II in the MM model with taxes, similarly to the model without taxes, concerns the amount of the cost of equity. This cost (k_{eL}) is equal to the cost of equity of unlevered company and risk premium, which in this case depends on a difference between the cost of equity of unlevered company and the cost of debt capital, tax rate and the amount of debt-to-equity ratio:

$$k_{eL} = k_{eU} + (k_{eU} - k_d) (1-T) (D/E),$$

According to the above, the cost of equity rises along with the amount of debt incurred. However, in this case the growth pace of the cost of capi-

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

tal is slower than in the MM model without taxes. The value of decreasing the growth pace in this model is described by the $(1-T)$ expression.

In the year 1977 M.H. Miller proposed the next version of the model that allows examining the relation between the company value and the cost of capital, called Miller model. This version included, apart from the income tax rate, also the personal taxes paid by the investors. According to this approach, the value of company financed by equity only is indicated by the formula:

$$V_U = \text{EBIT} (1-T_c) (1-T_e) / k_{eU},$$

where:

T_c – corporate income tax rate,

T_e – shareholder income tax rate on equity.

Furthermore, in case of financing using debt capital, the company value is a sum of the value of unlevered company and value added achieved on tax savings, as presented in the formula:

$$V_L = V_U + [1 - (1-T_c) (1-T_e) / (1-T_d)] D,$$

where:

T_d – personal tax rate on income from debt.

Within the frames of the model presented, Miller concluded that the value of tax shield is shaped by the corporate, shareholder tax rate and tax rate on income from debt (T_c , T_e , T_d) and by the market value of debt (D). The Miller Model works properly with the assumption that the market is in the state of equilibrium.

On the basis of MM theory or parallel to it new theories were created concerning the relation of the cost of capital with the company market value. They emphasize the relation of the cost of capital with the capital structure. One of theories that assumes a close relation of the optimal capital structure and the cost of capital is static trade-off model, grounded on the assumptions of F. Modigliani and M. Miller (Modigliani & Miller, 1958, pp. 261-297). In the static trade-off model it is presumed that the capital structure is optimal when the marginal value of tax benefits from additional debt is equal to the marginal value of the cost of financial distress resulting from increased debt. Along with debt increase the company market value

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

grows until some moment (the weighted average cost of capital is decreased). After reaching the point in which the benefits from using the financial leverage are equal to the increased risk connected with using debt capital, further debt increase causes decreasing the company market value. This point indicates the optimal capital structure (the weighted average cost of capital obtains there the lowest level and the company market value is the greatest) (Iwin-Garzyńska, 2010, p. 66). After introducing the income tax rate, the point of optimal capital structure is moved in the result of tax shield appearance. The tax shield causes that the cost of debt decreases. On the other hand, equity may be more expensive due to the income tax on dividend.

An extension of the considerations above is substitution theory that deals with the problem of mutual relations of benefits and costs connected with introducing debt capital into the company in the context of capital structure optimization in the company (Myers, 1984, p. 575). This theory assumes that the value of assets and total capital invested in the company is perpetual and consistently with this assumption, an optimal capital structure is sought that provides the highest company value. According to the substitution theory, shaping of the value of levered company is influenced by both tax benefits (resulting from including the interest on debt in the tax costs) as well as the costs of financial distress coming from the risk of insolvency that accompanies the utilization of debt capital (Nawrocki, Jonek-Kowalska, 2013, pp. 539-559). Consequently, the value of levered company may be expressed as follows:

$$V_L = V_U + PV_{\text{tax shield}} - PV_{\text{CFD}}$$

where:

V_L – value of levered company,

V_U - value of unlevered company

$PV_{\text{tax shield}}$ – present value of tax benefits from the tax shield connected with the interest on debt,

PV_{CFD} – present value of the costs of financial distress (Michalak, 2014).

The application of the cost of capital in practice of the company value pricing

Effectiveness assessment of management in the view of company value growth rises a need to adjust some universal, commonly accepted measures in theory and practice. The traditional financial indicators based on accounting data do not include all factors that affect the company value. Historically, the oldest asset methods of company value pricing use past data that may deviate from the current values and do not include the ability of the particular asset components of the enterprise to generate earnings. These methods do not take the change of currency value in time and the cost of capital into account. Their application in practice is rare. Nevertheless, greater popularity is gained by the measures of company value growth, based on the company ability to generate earnings. Such methods include: Discounted Cash Flow (DCF) and Dividend Discount Model. The first of them estimates the company value as a sum of present value of future cash flow generated by the company (Szwajca, 2010, pp. 212-223). The second one is based on a dividend where the company value is indicated by a discounted flow of future dividends. An increasingly popular alternative for DCF method is Economic Value Added (EVA). These methods provide the same results if the same assumptions are used in analysis, however, according to many authors, the EVA conception has some features that the DCF methodology lacks. It is emphasized that EVA is more complex and clearer in the context of monitoring the process of company value creation (Compare Stewart, 1991). Moreover, the EVA conception allows confronting the internal company results directly with the way they are perceived by the market, using Market Value Added (MVA). The cost of capital used for the company financing has great influence on the company value calculated by these methods (Compare Michalak & Sojda, 2014).

Market Value Added (MVA) measures the company value generated on the market in relation with the invested capital and constitutes a sum of discounted future value of EVA of the company (Boulton et al., 2001, p. 16). The method of economic value added is based on the calculation of operating profit, thus it refers to the operating part of company's activity only, abstracting at the same time from less important areas of activity for the company's existence. However, it also includes tax burden. Therefore, it may be stated that it reflects the actual potential of the company in terms of value creation. Furthermore, economic value added pays attention to the interests of investors (Basak & Pavlova, 2013, pp. 1728-58) using the bene-

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

fits expected by them in its formula. It includes the cost of capital engaged in the company's activity. At the same time EVA mitigates the disadvantages of the pricing methods presented earlier. It is worth adding that the conception of market value added (MVA), which uses the economic value added, beside the aforementioned factors important for the company activity, enables inclusion of time flow as well. This is possible because MVA constitutes a flow of discounted EVA in time.

In practice, for EVA calculation, Net Operating Profit After Taxes (NOPAT) is used (Compare Dudycz, 2001, pp. 198-201), decreased by the earnings expected by investors, expressed as a relation of Invested Capital (IC) and the expected return rate on the invested capital expressed by Weighted Average Cost of Capital (WACC). It may be presented using the following formula (Caputa, 2009, pp. 8-13):

$$EVA = NOPAT - WACC \times IC$$

where:

NOPAT – Net Operating Profit After Taxes,
WACC – Weighted Average Cost of Capital,
IC – Invested Capital.

In practice, NOPAT is net operating profit after taxes, that means a profit before deducting the costs of financing the company by debt capital but after deducting tax expressed in cash. NOPAT may be therefore calculated decreasing the operating profit by tax burden:

$$NOPAT = EBIT \times (1 - T)$$

where:

NOPAT – Net Operating Profit After Taxes,
EBIT – Earnings Before Income Taxes,
T - Income Tax rate.

On the basis of EVA, MVA is calculated. It is a sum of discounted EVA that will be achieved in the future periods $t=1,2,3,\dots,n$ and it reflects the premium obtained on the market due to the invested capital in the company (Ehrbar, 1999, p. 21):

$$MVA_t = \sum_{t=1}^n \frac{EVA_t}{(1 + WACC)^t}$$

where:

t – period of time,

MVA_t – Market Value Added,

$WACC$ – Weighted Average Cost of Capital,

EVA_t – Economic Value Added.

MVA expresses the present value of EVA obtained in future periods $t=1,2,3,\dots,n$. According to the above, if the company generates a flow of positive EVA values, the additional positive value will be gained, however, if the value of discounted EVA is negative, the process of value “damage” will occur. MVA provides a basic statement that a new value will only be created if the invested capital in the company provides a return higher than break-even point, indicated by the cost of capital.

As it results from the formulas above, the cost of capital is a very significant parameter appearing in MVA as a discounted rate. It also appears in the process of EVA calculation as the expected return rate on the invested capital by the investors in the company. This capital may be of equity or debt character.

Conclusions

The review of theory made above allows concluding that there are many conceptions confirming a close relation between the cost of capital and the company value, which are the measures of effective corporate financial management. The cost of capital appeared as the value pricing parameter in the middle of XX century in the conceptions of F. Modigliani and M. Miller and in the considerations continued by M. Miller himself. On the basis of these conceptions new models appeared in which the influence of the cost of capital on the company value is proved. These include: static trade-off model, signaling theory, agency dilemma, free cash flow theory. Taking into account that there is a number of methods confirming the relations between the cost of capital and the company value that have been created in the recent several dozen years as well as considering the current solutions used for this purpose in the practice of corporate financial management, the thesis stated at the beginning is positively verified.

Strengthening the Post-crisis Fiscal Rules – the Case of Spain, Slovakia and Sweden

JEL Classification: *H3; H62; H63*

Keywords: *fiscal rule; fiscal policy; public debt; budget balance; public finance*

Abstract: The purpose of this article is to identify changes in the development of national fiscal rules in response to the crisis, in terms of the new economic governance in the EU. In-depth analysis was carried out on the example of the three countries that have the highest Fiscal Rule Strength Index, i.e. Spain, Slovakia and Sweden. The conclusions of the study were the basis for the formulation of recommendations for Poland. The research focuses on the new rules as well as the rules modified between 2007 and 2012. The key elements of creating fiscal rules and criteria used for their evaluation were recognized. The research shows that the strength of fiscal rules is determined by their legitimacy, the type of institutions monitoring them, the adjustment mechanism and sanctions, as well as the scope of the public sector, which the rule was imposed on. Short duration of most of the rules limits the ability to evaluate their effectiveness. However, the analysis of changes in the finance sector and local government in terms of new institutional arrangements allowed to conclude that the strong fiscal rules index is not a guarantee of maintaining public finance discipline, and the example of this was the varied fiscal position of the countries surveyed.

Introduction

In recent years, there has been a significant increase of interest of the fiscal authorities of EU members in the use of numerical fiscal rules. To a large extent, this is due to the economic governance reform, launched in 2011, which was a reaction to the negative consequences of the recent financial crisis. The essence of the reform boils down to building a system for monitoring economic policy in order to have early detection of macro-economic imbalances and to strengthen the fiscal surveillance over national fiscal policies.

The Commission and the European Parliament have formulated a number of recommendations to the member countries, related to the conduct of the fiscal policy, including those relating to the institutional arrangements, such as fiscal rules. In accordance with the Council Directive (2011), strong numerical fiscal rules with explicit objective are to be the basis for enhanced budgetary surveillance framework, together with mechanisms for effective and timely monitoring.

The aim of this article is to identify changes in the development of national fiscal rules in response to the crisis, in terms of the new economic governance in the EU. The new rules as well as those modified between 2007 and 2012 were the subject of the study. An in-depth analysis was carried out on the example of the three countries that have the highest Fiscal Rule Strength Index (FRSI), i.e. Spain, Slovakia and Sweden. The conclusions of the research were used to prepare recommendations for Poland.

Methodology of the research

The starting point of the research was a review of the world literature on the characteristics of fiscal rules. Key structural elements of the rules and criteria used for their evaluation were identified, which allows international comparisons. On the basis of the latest Fiscal Rule Strength Index (European Commission, 2012), three countries with the highest standardized indexes were selected for the in-depth analysis. Changes in the types of existing rules, as well as their structural components, occurring under the influence of the crisis and the EU guidelines were studied starting from 2007, when the financial crisis had begun. The approach used in the research was that of the European Commission, based on the concept of Deroose, Moulin, Wierts (2006). Another element of the research method was to analyze the fiscal position of Spain, Slovakia and Sweden in the light of the applicable

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

national fiscal rules. The short period of time when the multiple rules were applied (especially those introduced in 2012) makes it impossible to evaluate their effectiveness. Nonetheless, even a preliminary assessment of the rules provided interesting results, also for Poland. The article uses the following abbreviations for the sectors: General Government - GG, Local Government - LG, Regional Government - RG, State Government - SG, social security - SS.

Review of literature on the characteristics of fiscal rules

Development of fiscal rules, observed in the last quarter of a century, has intensified in the recent years. It manifests itself not only in the increase in the number of rules, but also in important qualitative changes. While at the beginning of the 90s, national fiscal rules in the EU countries were used mainly in relation to the local government sector, rules covering the whole GG sector are now becoming common (EC, 2008, p. 76). There is also an increase in the importance and the number of transnational numerical rules, which are omitted in the article; it focuses instead on national institutions. However, it should be noted that many of the recently implemented rules in EU member countries are closely linked to the EU restrictions.

In the literature, there are many definitions of fiscal rules. The broader and narrower approach can be distinguished (e.g. Wójtowicz, 2011, p. 138). In broad terms, the fiscal rules are generally understood as standards governing fiscal policy. In this article, domestic fiscal rules are defined in narrower terms, according to the approach of Kopits and Symanski (1998, p. 3), most widely used both in the world and national literature. They define the fiscal rule as the permanent limitation of fiscal policy, which boils down to the imposition of quantitative restrictions on budgetary outcomes, such as the budget deficit, public debt or their main components. Restrictions can be expressed in absolute terms in relation to the above-mentioned elements, as well as in relation to economic variables. In other words, the policy rules may be permanent, or based on feedback. Constant policy rule is independent of the changes in the economy. The rule based on feedback is based on the relation between an increase/ decrease of some value and changes in a different category (e.g. in GDP).

Fiscal rules are defined as institutional mechanisms supporting the credibility of fiscal policy. Policy rules were primarily advocated by such economic schools as the monetarist orthodoxy, new classics, the real business cycle school, the Austrian School. In the literature, the advantages and dis-

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

advantages of using fiscal rules are indicated. Alesina and Perotti (1996) perceive fiscal rules not only as the tools to discipline public finances, but also as measures affecting the prosperity of society. Rules are also a useful institution according to Buchanan (1997, p. 130), who argues that in the absence of restrictions imposed on, for example, local authorities, the practice of the process of democratic choice could result in debt beyond the boundaries of "efficiency", although the rising costs of servicing the loan could also impose certain restrictions on the over-extension of expenditure. It is a mistake, however, to present an uncritical approach to fiscal rules because of the negative consequences for the economy and public finances. The imposition of excessively restrictive rules could result in the restriction of investment opportunities in the public sector and the need for verification of public tasks, by transferring a part of the funding to the commercial sector or separating the relevant public sector units performing public tasks (Marchewka-Bartkowiak, 2012, p. 49).

Restrictive fiscal rules may lead to the use of creative accounting in order to maintain power and political reputation. Such a hypothesis is formulated by Milesi-Ferreti (2003, p. 377 – 394). Empirical evidence of the correctness of this hypothesis was provided by Hagen and Wolf (2004). Their research shows that fiscal rules introduced in the Pact for Stability and Growth and the consequent excessive deficit procedure resulted in the use of creative accounting by the member countries. An uneven approach to exceeding the limit of the deficit and the debt limit (the procedure was activated only in the case of excessive deficit) contributed to this. Meanwhile, the increase in debt in the period preceding the global financial crisis in many countries of the EMU showed a weak association with the size of the accumulated deficits (public debt).

Similarly, Fourçans and Warin (2007, 51-62) tried, using game theory, to prove that institutional solutions in the Pact, reinforced in 2005, would not reduce the phenomenon of moral hazard.

Research conducted by representatives of science, for example. J.M. Poterba [1994] A. Alesina, R., Perotti, (1996), as well as international institutions, i.e. The International Monetary Fund (2009), show the effectiveness of fiscal rules. The intended objective, however, requires a good design of a fiscal rule. The quality of fiscal rules is determined by the type of rules and their elements.

With regard to the type criterion, we can distinguish the following rules: budget balance, debt, expense and income. In this article, the characteristics of the rules were not covered. I would like to refer the readers to publica-

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

tions by other authors (e.g. Działo, 2009; Wójtowicz 2011; Próchnicki, 2013, Marchewka-Bartkowiak, 2012; G. Paluszak, 2010). The article placed greater emphasis on the quality of fiscal rules which, in accordance with the assumptions, should improve the effectiveness of fiscal policy. Construction of high quality fiscal rules requires recognition of possible channels of influence on the economy and public finances. Buiter (2003, p. 84 - 99) formulated the Ten Commandments for a Fiscal Rule in the E(M)U, which can be used to design rules on a national level. According to Buiter the rule should be: 1) simple; compliance should be easily verifiable, 2) maintain the government's solvency, 3) apply to the financial deficit of the sovereign, that is, to the consolidated general government, 4) make sense also in the long run, 5) allow for relevant differences in economic structure and initial conditions, 6) make sense at the level of the individual nation state and for the EMU area as a whole, 7) credible, 8) enforced impartially and consistently. The rule should not: 9) prejudge the issue of the appropriate/optimal size of the public sector; 10) encourage pro-cyclical behavior of the policy instruments.

Research (Schaechter et.al., 2012) conducted in the period from 1985 to March 2012, using the sample of 81 countries, shows that the "new generation" rules are becoming more complex, combining the objectives of sustainable development with the need for flexibility in response to shocks. Thus, e.g. Agénor, Yilmaz (2011, 69-99) conducted research on the efficiency of alternative fiscal rules in a model of endogenous growth, demonstrating the advantage of the primary surplus rule over the balanced budget rule and the golden rule, from the perspective of long-term growth and response to shocks. From this point of view, it is interesting to combine the relationships between the fiscal rules and the key objectives of the country developed by IMF (2009, p. 6). They are presented in Table 1. They show that the expenditure rules and the rules of the limits of windfall gains interact with three main objectives, i.e. debt sustainability, economic stabilization and government size. You can see a very strong positive effect of the debt rule (expressed in relation to GDP) on the debt sustainability and the balanced budget rule over the cycle rule on the economic stabilization.

The information contained in Table 1 shows that, from the perspective of limiting pro-cyclicality, the concept which involves the construction of such fiscal rules that discipline public finances, leaving room for discretionary measures can be regarded as attractive.

These conditions are fulfilled by the balanced budget rule within the cycle. It gives a greater degree of freedom in the conduct of fiscal policy on a

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

discretionary basis, in connection with moving away from the absolute requirement to balance the budget by the end of each financial year to the requirement to balance the budget within one cycle.

Table 1. Properties of Different Types of Fiscal Rules against Key Objectives

Type of fiscal rule	Objectives		
	Debt sustainability	Economic stabilization	Government size
Overall balance	++	-	0
Primary balance	+	-	0
Cyclically adjusted balance	++	++	0
Balanced budget over the cycle	++	+++	0
Public debt-to-GDP ratio	+++	-	-
Expenditure	+	++	++
Revenue	-	-	++
Revenue ceilings	+	+	-
Revenue floors	+	+	-
Limits on revenue windfalls	+	++	++

Note: Positive signs (+) indicate stronger property, negative signs (-) indicate weaker property, zeros (0) indicate neutral property with regard to objective.

Source: IMF (2009, p. 6).

This rule is difficult to apply because the duration of the cycle must be precisely determined. Therefore, in practice, the EU has given high priority to the rule of a cyclically adjusted balance, which is to maintain a balanced structural balance in each year's budget.

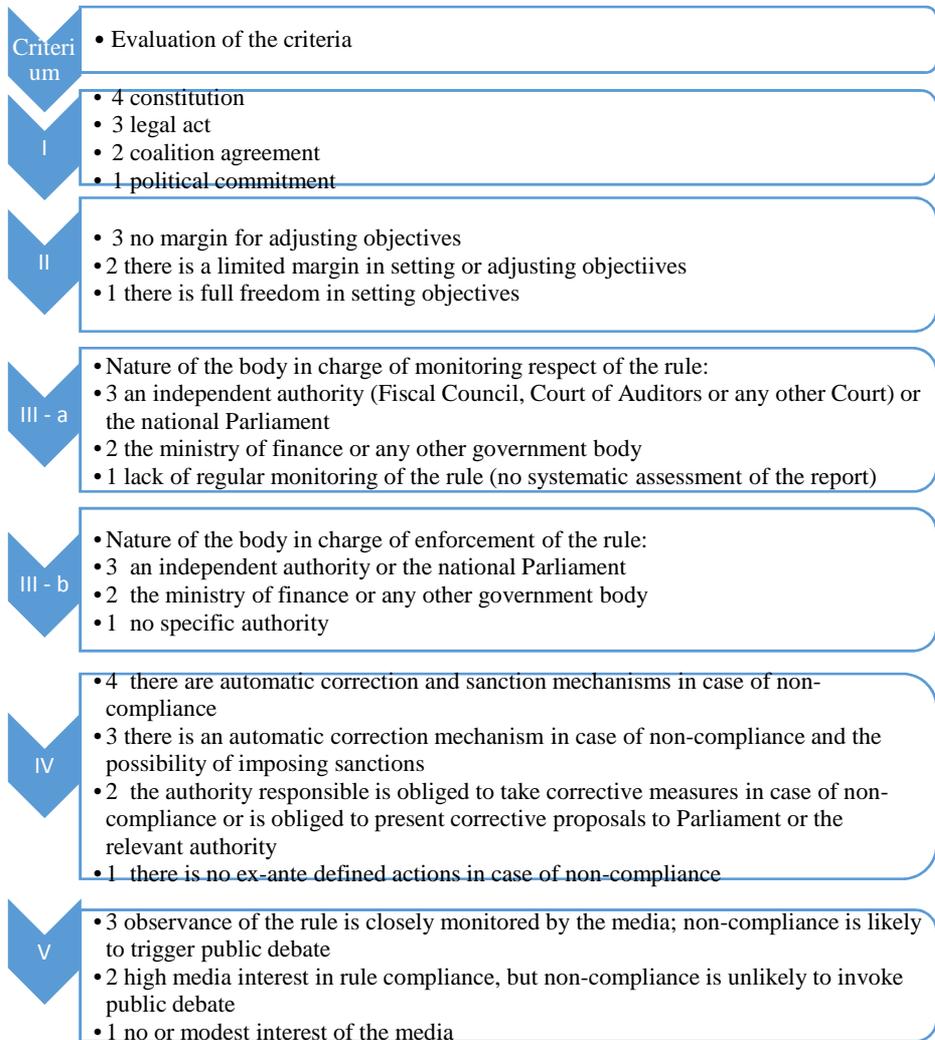

It is also worth noting that the quality of fiscal rules is determined by economic and institutional conditions in which it operates, so the IMF (2009, p. 32) issued a recommendation that the rule should not be introduced in a precarious economic situation.

Key elements of fiscal rules

Quality assessment of such institutional arrangements as fiscal rules, which allows comparability between countries, is carried out by international organizations (European Commission, IMF) on the basis of a synthetic indicator called the Fiscal Rule Strength Index.

Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

the rule, 4) the existence of pre-defined enforcement mechanisms, 5) media visibility of the rule (EU 2006, p. 163 – 164).

Indexes are calculated for each fiscal rule based on the criteria, the assessment of which is described in Figure 1 as well as the ratio of the public finance sector covered by the policy. The cumulative index of fiscal rules in force in the country is obtained by summing the individual indexes. If several rules apply to the same range of public finances, a weight system is used (the methodology was described in the EU in 2006, pp. 149 - 167).

On the basis of the scores of the criteria, it can be established that the highest index will be applied to the fiscal rule: a) incorporated into a legal act with constitutional status, b) with no margin for adjustment of objectives, c) monitored by an independent fiscal institution or parliament - with automatic mechanism of correction and sanctions in case of non-compliance, d) closely monitored by the media, e) covering the entire scope of the GG sector.

Table 2 shows the standardized index of fiscal rules in the EU in 2007 and 2012. The countries are ranked in descending order according to the index size in 2012. The difference in size between the study years, allows us to see the scale of strengthening of the fiscal rules, after negative experiences from the financial crisis.

Index of -1 means that the country did not use national fiscal rules. In 2007, this applied to Cyprus, Malta and Greece. Even in the context of new economic governance, Cyprus and Malta have not introduced national rules, whereas Greece has in 2012 implemented the primary balance limit in respect of the GG sector. The index at the level of 1.984 is an expression of the strength of this rule. The highest index has been granted to the rules in Spain (3.264). The index value greater than 2 characterizes the rules in Slovakia, Sweden and Bulgaria. Slovakia has strengthened the rules the most of all EU countries - the index rose from 0.305 in 2007 to 2.661 in 2012. It should be noted that in nine countries the index decreased between the study years, especially in countries where already in 2009 it remained at a low level (Ireland, Slovenia, Italy, and Czech Republic). In the ranking of the strength of fiscal rules, Poland has a very high 5th place with an index of 1.935. It is significant that in Poland the index was higher in 2007 than in 2012. It is the result of a lower assessment of the institutional arrangements applicable to the local government sector (debt limit, deficit limit) according to the criterion of "media visibility of the rule" (2 in 2007, and 1 in 2012 - figure 1).

Comparison of rules functioning in Spain, Slovakia and Sweden

The rest of this article provides an in-depth analysis of the countries with the highest index of the EU fiscal rules. Table 3 summarizes the rules functioning in Spain, Slovakia and Sweden in the period under observation, indicating its scope (coverage of GG finances).

In all three countries, there were rules that imposed restrictions for the budget balance and public expenditure. In Spain and Slovakia the debt rules are additionally applied to both the local government sector as well as the GG. In Sweden no national debt limits have been introduced. In order to present the diversity in the field of applied solutions in different countries their characteristics are presented below.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

Spain

In Spain in 2007, four fiscal rules were functioning, three of which referred to debt limits, and one to budget balance. The index in 2012 has been calculated on the basis of five fiscal rules, three referring to the debt, one which is the limit for the budget balance and one which is the limit for the public expenditure. In the period under observation, the rule relating to the budget balance has changed. The rule (ES-1), introduced in 2006, according to which budgetary objectives should take into account the cyclical nature of the economy, allowing budget deficits in periods of economic downturn (no more than 1% of GDP), with the requirement of the surplus in periods of high growth, remained in force until 2011. From 2012 onwards, more restrictive rule (ES-2) applies, according to which the government deficit (CG) and the deficit of the Autonomous Communities cannot exceed the limit set by the European Union and the budget of municipalities must be balanced. The rule covers 97.5% of the GG sector and has the strongest index of the rules in force in the country (8.77). The advantage of the current rule over the pre-existing one lies in the fact that it is incorporated into the Constitution and is subject to the automatic mechanism of correction and sanctions. The previous rule was introduced by a legal act of lower rank and did not define what actions were to be taken in case of exceeding the limit.

Table 3. The scope and strength of fiscal rules in selected EU countries in the period of 2007 - 2012

Note: BBR – budget balance rule; DR – Debt rule; ER – Expenditure rule.

Source: the same as Table 1.

The main rule relating to public debt (ES-8) also has a firm legal basis. Like the budget balance rule, it is incorporated into the Constitution and it is an expression of the implementation of the obligations of membership in the EMU. According to it, the debt of the GG sector must not exceed 60% of GDP. A characteristic feature of the rule is that its scope includes the GG sector, but the limits are different for the sub-sectors, i.e. 44% - Central Administration, 13% - Autonomous Communities, 3% - Local entities. Indicators refer to the entire sub-sector, hence the law (Ley Orgánica 2/2012, art. 14, par. 1) clarifies that the debt limit in each of the autonomous regions must not exceed 13% of the gross regional product. An automatic mechanism of correction and sanctions is built into the rule.

In Spain, since 1990, two rules on financial supervision apply - regarding the debt of the local sub-sector (ES-3) and the debt of the regional sub-sector (ES-4). The first one shows that the central government, or the Autonomous Communities, are authorized to approve all long-term credit operations carried out by the local authorities, if they have negative net savings or debt exceeding 75% of the current income. According to the second rule, borrowing by regional authorities requires the authorization of the government. In the period of 2003 – 2011, the debt of the RG sector was tightened by one more rule (ES-5), which obliged each unit of the local government to maintain the debt in nominal terms at the same level at the beginning and at the end of the financial year.

Reduction of expenses in the form of a numerical fiscal rule was introduced in Spain only in 2011. (ES-6). The limit was imposed on eligible expenditure growth, which, on an annual basis, must not exceed the medium-term growth rate of GDP, calculated on the basis of the average size of the GDP in nominal terms for a period of 9 years. In 2012, restrictiveness of expenditure rule (ES-7) was increased, through the extension of the scope of its applicability and by connecting it to automatic mechanism of correction and sanctions for non-compliance with the limit.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

Sweden

In Sweden, there are two rules relating to the budget balance. In 2002 they introduced the principle of maintaining balance of the GG sector at 2% of GDP over the cycle. In 2007, this rule was mitigated by adopting the criterion of 1% of GDP (SE-4). Since 2007, the rule operates on the basis of the Constitution before that it was regulated by the coalition agreement.

The second rule (SE-1) includes only the LG sector, forcing its subjects to maintain a balanced budget.

The implementation of the budget surplus is favored by the expenditure rule. It was introduced in 1996, but it was modified in 2007 (SE-2) and 2010 (SE-3). The essence of this rule is to establish a maximum spending limit of the central level and the expenses for pensions, which are settled in a non-budgetary system. Since 2010, a three-year planning period has been introduced. Apart from the rule, expenditure on public debt is allowed.

Slovakia

In Slovakia, the national rule of the GG sector balance has not been introduced. However, the rule disciplining the local government budget (SK-3, SK-4) has been functioning since 2002. It is based on highlighting the operating and the capital budget. The operating budget (current), must be sustainable or closed with a surplus. There is a deficit option in the capital budget, provided that unused funds from previous years, loans or a budget surplus in the current fiscal year are the source of its funding. In 2009, the possibility of imposing sanctions on the municipalities in the case of non-compliance with the principles was introduced.

At the same time, the debt limit (SK-3) was imposed on the local government sector (regional and local). The limit was set at 60% of the nominal current income in the previous year. The limit was also imposed on the annual installments of debt repayment, which must not exceed 25% of the nominal income in the previous financial year.

The implementation of the obligations arising from the signing of the Fiscal Pact in 2012 resulted in the introduction of a new debt rule which, within its scope, included the entire GG sector (SK-6). The rule was introduced by the Fiscal Responsibility Constitutional Act. The solution resembles prudential and remedial procedures operating in Poland since 1998. In Slovakia, four debt thresholds were introduced: 1) 50-53%; 2) 53-55%; 3) 55-57%; 4) 57-60%. The thresholds are to be applied until 2017, when they

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

will be reduced so that the highest rate in 2027 will be 50%. It should be noted that it is this fiscal rule that has received the highest index ratio of 9.71. Polish remedial and prudential procedures were granted the index of 9.05, mainly due to the smaller range of coverage of the public finance sector rule (97.5%).

Expenditure rule has applied in Slovakia since 2002. It also allows an increase in expenditure not included in the budget act during prosperity. Initially, the spending limit was set at 15% of total expenditure approved in the budget, and now it is 1%.

The spending can be increased only if the deficit remains unchanged. In 2012, the coverage of the rule was extended so that it included 48.6% of its public finance sector (previously 47.2%). Despite the tightening of the rules and expanding its range, the index of the rule decreased. This was caused by a decrease in media interest in the rule, which resulted in lower assessment of the rule, according to the "media visibility" criterion.

Characteristics of fiscal rules in Spain, Slovakia and Sweden will be extended to include the assessment of the institutional solutions adopted, on the basis of the assessment of the characteristics of the fiscal rules according to the criteria listed in Figure 1. In this analysis, attention was focused solely on the rules relating to the GG sector. The exception is to include expenditure rule in Slovakia, which is superimposed on the CG sector rather than on the GG sector. Due to the lack of the debt rule in Sweden, and the rule of the GG sector balance, comparisons in case of balance and debt rules will be carried out between the two countries, in which the rule can be found. Assessment of the rules is provided in Table 4.

The best score in the Fiscal Rule Strength Index (FRSI) was granted to the expenditure rule in Sweden. Its biggest advantage over the rules in other countries is that it is closely monitored by the media, so in case of a failure to comply with it, there is a high probability of a call for a public debate. In Slovakia and Spain the media interest in the rule is negligible. The expenditure rule in Spain, where the index is lower by 1.1 percentage points than the same index in Sweden, shows an advantage in connection with the built-in mechanism of action in the event of occurrence of non-compliance. The high assessments of expenditure rules in the countries surveyed consisted of such elements as their incorporation into a legal act and a lack of margin for adjustment of objectives.

In Spain, the budget balance rule, implemented in 2012, received better grades from the rule functioning since 2007 in Sweden. In the period of

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

2006 – 2011, the balance rule in Spain has already functioned, and its index was at the same level as for Sweden (6.66).

Table 4. Evaluation of the rules referring to the GG sector

	Statutory base	Adjustment margin	Monitoring body	Alert mechanism	Enforcement body	Non-compliance actions	Escape clauses	Media visibility	Fiscal Rule Strength Index
Debt rules									
Spain	4	3	2	1	2	4	1	1	8.11
Slovakia	4	3	3	0	3	4	1	3	9.71
Balance rules									
Spain	4	3	2	1	2	4	1	2	8.77
Sweden	3	2	3	1	1	1	0	3	6.66
Expenditure rules									
Spain	3	3	2	0	2	4	0	1	6.92
Slovakia (CG)	3	3	3	1	3	3	0	1	7.38
Sweden	3	3	3	1	2	2	0	3	8.02

Source: the same as Table 1.

The improvement is due to the strengthening of the rule in the aftermath of the crisis. In Spain, the rule was introduced into the Constitution and did not leave any margin for adjusting the objectives. An automatic mechanism of action in case of non-compliance was introduced. In Sweden, the rule is provided in a legal act of a lower rank than the constitution, and some margin in setting or adjusting the objectives is allowed. In the construction of the expenditure rule, greater emphasis was placed on the monitoring system, and the system of correction and sanctions was not accepted. As in the case of the expenditure rule, the media in Sweden show more interest in the rule than they do in Spain, which promotes the discipline of public finances. In Sweden, the rule covers the whole GG sector, while in Spain it covers 97.5%.

In case of the debt rule of the GG sector, the structure adopted in Slovakia was highly rated (9.71). Both in Slovakia and Spain the implementation of rules in 2012 was a part of disciplining measures aimed at public

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

finances in EMU, in accordance with the guidelines of the new economic governance.

In both countries the rules received equally high marks for their legal basis in the constitution, disregarding the margin for adjustment of objectives, automatic mechanism of correction and sanctions, and the rule covering the entire GG sector. A higher value of the debt rule in Slovakia is the result of a stronger monitoring system of respecting and enforcement of the rule, as well as greater interest in the media.

With regards to the rules in force in Spain, it can be noticed that their weakness is the fact that the institution that monitors their compliance with the rules is the Ministry of Finance. The supportive function is fulfilled by the institutions of the regional sector, which control the fulfillment of the debt rule. In terms of monitoring the compliance with the rules, Sweden is the role model, as such powers have been given there not only to the Ministry of Finance and other institutions of the government sector, but also to the independent institutions, i.e. The Court of auditors.

The strengthening of the fiscal rules in the aftermath of the crisis is manifested by a change of their legitimacy. Table 5 presents rules, classified according to the criterion of the legal basis in 2007 and 2012.

Table 5. Legitimacy of the fiscal rules

	Constitution	Legal act	Coalition agreement
2007 r.			
Spain	X	ES-1; ES-3; ES-4	ES-5
Slovakia	X	SK-1; SK3; SK- 4	X
Sweden	SE-4	SE-1	SE-2
2012 r.			
Spain	ES-2; ES-8	ES-3; ES-4; ES-7	X
Slovakia	SK-6	SK-2; SK-3; SK-5	X
Sweden	SE-4	SE-1; SE-3	X

Source: the same as Table 1.

It draws attention to the increase in 2012 of the number of rules incorporated into the constitution, which is to be a guarantee of their sustainability and compliance. While in 2007, only Sweden has given constitutional status to the fiscal rule (budget balance), in 2012 each of the countries surveyed had such a rule. Constitutional authority with regards to fiscal rules

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

in the countries within the euro area is a consequence of adopting the Fiscal Pact.

Slovakia incorporated the debt rule into the constitution, and Spain did the same with both the debt rule and the budget balance rule. Other rules are provided in legal acts of lower rank. In 2012, there were no rules, introduced on the basis of the coalition agreement. In Spain, the debt rule for the RG sector, based on the coalition agreement, was in force in the period of 2003 – 2011. Coalition agreement was the basis for the imposition in 2007 of the expenditure rule on the CG and SS sectors. Since 2010, the expenditure rule is based on a legal act.

Due to restrictions on the volume of the article, detailed solutions for the construction of fiscal rules, such as the exemption from the rule or the mechanism of correction and sanctions were not characterized.

However, as the mechanism of correction and sanctions was a rare element of the rules before the crisis, it was decided that an example of such a solution should be built into the debt rule in Slovakia. This mechanism means that when debt-to-GDP ratio reaches 50 percent, the Minister of Finance is obliged to explain the increase to parliament and suggest measures to reverse it. At 53 percent of GDP, the cabinet shall pass a package of measures to trim the debt and freeze wages. At 55 percent, expenditures would be cut automatically by 3 percent and next year's budgetary expenditures would be frozen, except for cofinancing of EU funds. At 57 percent of GDP, the cabinet shall submit a balanced budget (IMF, 2009, s. 22).

Changing the fiscal position of the surveyed countries

According to J. Działo (2009, p. 2) "rules seem to be an effective instrument because of their simplicity and transparency." These characteristics of the fiscal rules do not prejudice the effectiveness of the rules, the assessment of which must be based on the degree of realization of the objectives. The results of empirical studies confirm the positive impact of fiscal rules on budgetary outcomes (EU, 2008, p. 77; Poterba, 1996). However, caution should be exercised when interpreting the results because the changes which have occurred in the budget expenditure, balance and debt can be attributed to the influence of other factors.

Most fiscal rules, which have received high marks, have functioned only from 2012 onwards. It is difficult to assess the effectiveness of the rules, but it allows for the formulation of some initial conclusions. The research

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

period was extended by two years, i.e. 2006, which preceded the assessment of rules in 2007 and 2013 – the last year with available data.

The data in Table 6 shows that the lowest public debt occurs in Sweden, and it was achieved despite the absence of a national debt limit. In addition, the debt in relation to GDP between 2006 and 2013 decreased in this country by 4.6% of GDP and remains well below the EU rule (60% of GDP).

In Spain, - the country with the highest number and strength of fiscal rules, the debt level increased by 53.2 percentage points. The increase of debt by 23.9 percentage points also occurred in Slovakia, but its size is below the convergence criterion.

Table 6. Debt of the GG sector (% GDP)

	2006	2007	2008	2009	2010	2011	2012	2013	Difference 2013 : 2006
Spain	38.9	35.5	39.4	52.7	60.1	69.2	84.4	92.1	53.2
Slovakia	30.7	29.8	28.2	36.0	41.1	43.5	52.1	54.6	23.9
Sweden	43.2	38.2	36.8	40.3	36.7	36.1	36.4	38.6	-4.6

Source: Eurostat.

In Spain, after the budget surplus in 2006 and 2007, there were high, even double-digit, budget deficits every year in subsequent years. This occurred despite the budget balance rule, imposed on the GG sector, functioning since 2006. Strengthening of this rule in 2012 by means of the above arrangements is to contribute to the increase of fiscal discipline.

Table 7. Budget balance of the GG sector

	2006	2007	2008	2009	2010	2011	2012	2013

Source: Eurostat.

In Slovakia, where the national budget balance rule has not been introduced, after a marked increase of deficits in the years of crisis, in 2013, the excessive deficit was eliminated. Finally, in Sweden, in which there is both the balance rule for LG sector, as well as balance rule for the GG sector, incorporated into the Constitution since 2007, the fiscal situation is the best. In the period of 2006 – 2008, Sweden showed a budget surplus, and in sub-

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

sequent years, the budget was balanced or there was a small deficit (from -0.1% to -1.3% of GDP). This is all the more noteworthy considering that in 2009, the most acute year for the EU, it was Sweden that had the highest decline in GDP in comparison with the countries surveyed, as well as the highest output gap (Table 8).

Table 8. Cyclical adjustment of budget balances based on production function approach against the GDP and the output gap (prices from 2005)

Respecting the rule to maintain the budget balance at the level of 1% of GDP over the cycle has resulted in structural surpluses in the 2006 to 2013 period in the range of 0.1 - 2.7% of GDP.

In Spain, the structural deficits have occurred since 2008, and in Slovakia during the whole period under consideration. The solutions, adopted in the fiscal Pact, with regards to the size of MTO, which forced the EMU countries in particular to strengthen the national fiscal rules, have a positive impact on its implementation.

In all the countries surveyed, institutional solutions for the local government sector were successful, which is reflected in the budget balance for the LG sector (table 9), which is close to balance. Accordingly, there is a debt stability in the local sector. For example, in Spain, the local debt was 2.7% of GDP in 2006 and 4% of GDP in 2013. In Slovakia, the changes in the amount of debt between 2010 and 2013 reached 0.5 percentage points

**Proceedings of the 8th International Conference on Applied Economics

18-19 June 2015, Economics and Finance**

(from 2.7 to 2.2% of GDP) and in Sweden it was 2.1 percentage points (from 5.4% to 7.5% of GDP). In Spain, the deficit of the SG sector peaked in 2011, i.e. it reached 5.1%, but in 2012 and 2013 it fell below 2% of GDP. This sector is responsible for 20% of GDP of public debt in Spain.

Source: Eurostat.

Countries covered by the research show significant differences in the size of public spending. In Spain and Slovakia public spending is below the average for EU28 (49.1% in 2013) and in Sweden, were in all years it exceeded 50% of GDP, it is above the average for EU28. Between extreme years, the biggest increase in expenditure was recorded in Spain by 6.4 percentage points. The increase in Slovakia was 2.2 pp., and in Sweden in 2013 it remained at a comparable level as in 2006 (a difference of 0.1 percentage points). Data on changes in expenditures in Sweden are a confirmation of the implementation of the country's sound fiscal policy (economic). The increase in public spending was temporary in the most difficult economic times, after which it decreased.

Table 10. Expenditures of the GG sector as a percent of GDP

	2006	2007	2008	2009	2010	2011	2012	2013	Difference 2013 - 2006
EU28	46.2	45.5	47.0	51.0	50.6	49.0	49.4	49.1	2.9
Spain	38.4	39.2	41.4	46.2	46.3	45.7	47.8	44.8	6.4
Slovakia	36.5	34.2	34.9	41.6	39.8	38.9	38.2	38.7	2.2
Sweden	52.7	51.0	51.7	54.9	52.3	51.5	52.0	52.8	0.1

Source: Eurostat

Looking at the changes in the size of public spending in Spain, it can be assumed that its reduction in 2013 shows the relationship with the expenditure rule, reinforced in 2012. Both in the case of the expenditure rule as well as the other rules, verification of their effectiveness will be possible in a few years.

Conclusions

The growth of the fiscal rules in the EU countries, observed in recent years, is due to the modification of the EU fiscal framework, in accordance with the concept of the new economic governance, which is a response to the recent financial crisis. In the period covered by the research, the EU countries introduced new fiscal rules as well as strengthened the existing solutions. From the countries selected for analysis, the least fiscal rules characterized by the least variability occurred in Sweden. Spain applied the most rules in its fiscal policy. The introduction of the debt rule for the GG sector and strengthening of the fiscal rules in Spain in 2012, in accordance with the regulations for the member countries of the euro area, resulted in Spain obtaining the highest rank in the EU Fiscal Rule Strength Index. Sweden was third in the ranking and this country had a high index already in 2007, and within the time covered by the observations, it made only one change in the legitimacy of the expenditure rule.

In the ranking of fiscal rules, Poland was ranked fifth, with the index of 1.935, which means a reduction of 0.167 percentage points, when compared to 2007. The debt limit, stated in the constitution in 1997, received the highest grade. The limit was strengthened by prudential and remedial procedures included in the Public Finance Act (index (9.05)). The expenditure rule received a rating of 7.47. The indexes of fiscal rules in 2012, relating to the LG sector, received the value of 6.58 for both the deficit rule and the debt rule.

On the basis of the conducted analyzes, the following conclusions can be drawn for Poland in this article:

Firstly, the introduction of fiscal rules should be preceded by research of their potential impact on economic stability.

Secondly, in order to achieve a high index of fiscal rules it is necessary to create solutions using highly ranked institutional key elements of fiscal rules.

Thirdly, we must remember that a strong index of fiscal rules does not guarantee the maintenance of public finance discipline, as demonstrated by a varied fiscal situation of the countries surveyed.

Fourthly, the case of Sweden stimulates a reflection that public finance discipline can be maintained without imposing an increasing number of fiscal rules, with built-in mechanism of correction and sanctions, etc. but by conducting prudent fiscal policy over the business cycle.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?

Fifthly, sound fiscal policy requires simultaneous approach to the expenditure and revenues (Owsiak, 2014); Uncritical approach to cuts in public spending in the conditions of adopted restrictions, requires verification of tax policy of the state.

Sixthly, when exacerbating the restrictiveness of national fiscal rules, the experience of the EU countries should be taken into account, avoiding the transnational rules.

Seventhly, to increase the effectiveness of fiscal policy in Poland, the establishment of an independent fiscal institution should be considered rather than introducing further quantitative restrictions. The institution, independent of the fiscal authorities, would increase the credibility and transparency of the policy, provide support for the government in respecting national and transnational fiscal rules, and, at the same time, constitute an obstacle to the hiding of discretionary decisions made by politicians from the public, resulting in deterioration of public finances (Moździerz, 2012, pp. 85-86).

**Regional Innovation Programs' Sustainability
Under Risk and Uncertainty**

JEL Classification: *G29*

Keywords: *innovation program; region; sustainability; risk factor; system optimization*

Abstract: Globalization in economy has been taking on an ever greater significance recently. Particularly important it is becoming now to such leading-edge technologies in economics as regional innovation processes. The current stage of the development of regional economies differs from the past ones in that the role of innovation programs acquires ever more importance and that forming and designing of such programs becomes now a much more independent process; all this has led to a situation where we have to revise our system of economic methods and ways of managing the risks of a regional innovation program. The existing methods and ways of risk assessment and risk management for innovations are to be complemented by new approaches reflecting the market changes and the advent of new financial instruments and stratagems. In this paper I investigate the issue of applying the system optimization method to the task of building the uncertainty/risk evaluation model for the management of a regional innovation program, proceeding from the method of limiting factor values which reduces the design value of an investment efficiency parameter to its critical limit for direct problems. As a result of my study, I propose the model of a regional innovation program's sustainability zone under risk and uncertainty, using the MATHCAT software.

Introduction

Currently the world community is going through globalization processes, whose first stage dates back to the dawn of civilization. It was as early as IV century B.C. that the first ever state in the Globe was formed and established. By early XX century the territory of the Earth had been finally divided between existing states. And about practically the same time (1990) did begin the second stage of globalization going on till the present day. By this we want to say that when globalization comes to its end, there will ensue effective dissolution of the world community only to give rise to a new cycle of the process. Based on the above, one can come to a conclusion that the process of globalization has a cyclic nature subject to well-known development laws, namely centralization and decentralization. The properties of economic cycles and their functioning are interestingly investigated and summarized in: Schumpeter J., 1939, pp.123-130. It seems to be quite clear that the globalization processes will not come to their respective end in the foreseeable future.

The holistic and cyclical nature of the development of international community allows us to view globalization, on the one hand, as a process, or, on the other, as a system at a certain development stage. The following works investigate how innovation processes unfold themselves in the context of globalization: Vambery R.G., Mayer P., 2012; Dreher A., 2006; Sirgy M.J., Lee D., Miller C., Littlefield J.E., 2004; Tsai C., 2007; Dosi G., 1988; Nikolova L.V., Rodionov D.G., Mokeeva T.V., 2014. If we presume that the global community is a system, then it may be said that it must perforce possess all attributes and properties of a system. This, in its turn, gives us grounds for singling out a subsystem in it - a geographical region having its own innovation program. The 'region' subsystem is also a system (Asheim B., Getleer M., 2004, pp. 121-125) comprising among other things a set of innovation programs (Bataev A.V. (2014); Nikolova L.V., Sergeev D.A., Omelaynenko A.R. (2014); Rodionov D.G., Fersman N. G., Kushneva O. A. (2014); Rodionov D.G., Guzikova L. A., Rudskay I.A (2014), Rodionov D.G., Rudskay I.A., Kushneva O.A. (2014). This thesis provides the author with enough grounds for handling not individual objects but systems with their appropriate emergent and synergetic dimensions.

Goal of the study: to substantiate the sustainability of a region's innovation programs under uncertainty and risk. In order to achieve the above goal

we use the mathematical methods of system optimization: single-criterion methods and multi-criteria methods.

Methodology of the research

Risk management methods and procedures

Conventionally, there are two types of economic and mathematical methods of investment risk assessment for primal and reverse problems in risk management: quantitative and qualitative ones. To quantitative methods belong: design of experiment, spiral risk model, analog approach or conservative forecasts, risk-adjusted interest rate method, scenario analysis, decision tree method, sensitivity analysis, simulation approach. To qualitative methods belong: Delphi approach, SWOT analysis.

A review of research literature on the issue of applying mathematical models (Buyanov V.P., Kirsanov K.A., Mikhailov L.A., 2002; Stubbs W., Cocklin C., 2008; Short S.W., Rana P., Bocken N.M.P., Evans, 2012; Visnjic I.A., Bart V.L., 2012; Arkadiusz Borowiec, 2013.) demonstrates that not all the models have been substantiated mathematically and methodologically. As we know, a mathematical model is an approximated description of a certain class of phenomena denoted by mathematical symbols. By analysing a mathematical model we are able of getting an insight into the nature of objects under investigation. A mathematical model is undoubtedly a powerful tool for obtaining knowledge of the world around us as well as forecasting and controlling things. The models proposed by S.C. Myers and G.A. Pogue the "Longer" model of financial planning and the model of the best cash asset placement (capital planning problem) - are widely adopted by colleagues and used in the methods of sensitivity assessment and scenario analysis. Recently, other models have been getting popularity – those proposed by M.V.Gracheva (project efficiency assessment model with regard for risk-aversion measures; optimization of integrated risk cost model; optimization of integrated internal and external risk costs model); these are also used for sensitivity analysis and scenario analysis tasks. The complexity of calculating the probability-simulation models of assessment, management and optimization proposed by A.G.Novokreshchenov – based on the method of simulation modelling – has led to a situation where such models are very rarely applied to the practical problems of investment. Such models can be successfully applied to the tasks of risk assessment and innovation project management, along with

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

risk assessment and management of regional innovation programs. Uncertainty and risk belong to the objective side or aspect of the innovation process; they are its integral parts bearing on all phases and milestones of its implementation.

Suppose there is a hypothetical model of an innovation process which is a system made up of two interplaying sub-systems: the sub-system of risks composed of risk factors, and the sub-system of conditionally defined implementation stages. The combination of the sub-systems is essentially a model of implementation of real innovations. regional innovation process is also defined as a combination of these sub-systems and can be described as a closed-loop process (cycle), i.e. an innovation system that is subject to the laws of the theory of optimal control of systems. The innovation system is a range of programs – of all scales and sizes - whose implementation implies risks both while solving current and long-term investment tasks. The total variety of approaches to the study of systems can be broken down into analysis and synthesis, which, in their turn could be grouped as follows: analysis – functional or structural, synthesis – emergent (that defines coherence of a system) or synergetic (co-acting, multiplicative effect). The *emergent* properties of investment are linked to the fact that the system acquires new characteristics or qualities belonging to neither of the sub-systems (elements). The rise of *emergent properties* and *emergent risks* in the system can be used as a basis for the method or procedure of defining the systemic qualities of this investment object (see: Buyanov V.P., Kirsanov K.A., Mikhailov L.A., 2002). To reveal *emergent risks* (risk-factors) is one of important tasks in a study; however, it leads solely to the ascertaining of the fact that the interplaying objects begin to acquire new properties. In part this question can be answered with the help of *synergetics* – a science studying the processes and laws of self-organization. The science that does not take systemic risks into account assumes that by an external action upon an object you can always get the desired effect, i.e. transform the object in the way a researcher wants it to. Yet, experience demonstrates that in most cases this is more than problematic. Difficulties related to the process of innovation risk management can be accounted for by the fact that we do not have unambiguous data on the mechanisms regulating certain inner processes, which makes the author of this study limit it to the description of risks as final functional relations.

Given more factors to take into account, logic algebra methods are used in order to make a preliminary conclusion concerning the factors' significance. First we have to quantize the working variation ranges into individu-

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

al levels and then, by the method of Boolean functions' minimization, build a Boolean model of the system. At the next step we solve the task of the informal interpretation of the Boolean models.

While proceeding from the qualitative to quantitative analysis of the system's structure, we have to check if the previous results – both quantitative and qualitative – can be used for the evaluation of the system under investigation. There are various methods of such verification to be used here; they differ: by the degree of isomorphism, by the method of choosing the verification rule, by the tools used to find this verification rule. In its simplest form, structural analysis investigates a definite structural component of the system (in our case it means risk-factor). What we actually investigate using this approach are the properties of structural components at different levels when building the model of risk management. The approach I propose here allows us to substantiate the systemic nature of the assessment and management of regional innovation process risks and to create a framework for further studies. To build a model of regional innovation program risk management we have to identify the methodological, procedural and operational principles that can coherently bind together various interests at the macro- and micro-level existing in the region under investigation.

1. The methodological principles, i.e. the ones which determine conceptual fundamentals for regional investment, are the most general and – which is even more important – independent from the specific nature of the type of risk being investigated (they can be even invariant in relation to the concrete semantics of the goal and of value paradigms). For the purpose of shaping the methodology of investment in the region we apply the optimal system control theory and the methods of system analysis.

The methodological fundamentals also imply taking into account the modern specificities of investing that help us substantiate new approaches to the task of building a model of innovation risk management in a given region. The following rules underlie this principle:

- similarity of risks – this means that each participant's perception of risk is the same as that of all others';
- positiveness of risks – this means that the integral risk index lies within the acceptable threshold. In innovation programs this principle is generally associated with the principle of efficiency/performance;
- objectivity of risks – this means that for risk assessment we have to correctly formulate the structure and properties of the changing object;

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

- correctness of risks – this means that the risk assessment procedure is subject to certain formal requirements, such as:
 - a) accumulative monotonicity: meaning that - within a certain exponent range - if activity intensifies the risk also grows; at the same time in boundary zones uncertainty is measured qualitatively;
 - b) non-direct proportionality – this means that the growth of risk is not directly proportionate to the intensification of activity (in the given exponent range);
 - c) transitivity – this means that if situation "a" is less risky than situation "b", and situation "b" is less risky than situation "c", then situation "a" is less risky than situation "c";
 - d) additivity – this means that risk is equal to the sum of particular risks:
 - risk integration – this means that taken as a whole risks have to form a closed system;
 - interdependency of risks – this means that when some risks arise other risks also arise due to interaction effects.
- 2. Procedural principles – i.e. the ones directly associated with the content of the innovation program, its specific characteristics, implementation, and real situations. The following rules underlie this principle:
 - dissonance of risks – this means that each new project impacts the innovation program in its own specific way; the stronger is the dissonance of the new project, the higher is the risk;
 - different perception of risks – this means that different projects making up the program have their risks, which determines the incongruity of interests of project participants and differing attitudes towards possible damage or loss;
 - dynamism of the risks constituting an innovation program means that procedural support takes into account the changing nature of risks;
 - risk coherence in the innovation program means that prevention processes have to be coordinated with other processes, when risks arise.
- 3. Operational principles, i.e. those linked to the availability, reliability and unambiguity of information, and tools at hand to process it.
 - modulability of innovation *program*' risks determines a situation when the arising risks can be described with the help of a model;
 - simplifiability of innovation *program*'s risks tells us that while assessing risks we choose the method which is most simple from the calculation or computing point of view.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

As a result, I have framed a methodology for investigating the problem of sustainability of regional innovation programs under uncertainty and risk. I also identify and define methodological, procedural and operational principles relying on the rules which were used for building the model of risk management.

**System optimization of risk for a regional innovation program
Risk management optimization theory - fundamentals**

The investment sensitivity method is a single-criterion optimization problem, which means that for its implementation only one efficiency function is used, namely the factor impacting innovation efficiency. I propose to consider the further development of sensitivity analysis i.e. to move from single-criterion analysis to multi-criteria one on the basis of S.Pontryagin's analytical procedure, i.e. to solve limited variational problems occurring when we have to optimize control and management in dynamic systems. The analytical procedure proven by S. Pontryagin is used for substantiation of the method of sustainability of a regional innovation program under uncertainty and risk. The method of defining investment sustainability ensures the calculation of the limiting factor values that impact investment efficiency when solving direct problems.

The theory of forming a regional innovation program and its properties help us optimize innovation risks and manage them. One of the particularly troublesome tasks pertaining to making an innovation program of a region is the necessity of using synthesis for the assessment of innovation efficiency. A regional innovation program is a multifaceted dynamic system for the management of whose risks many risk criteria have to be used (risk-factors). In some cases these risk-factors can be reduced to one risk, thus returning the solution procedure to the well-known method of single-criterion optimization. The simplest method of such reduction is the so called *weighting of criteria*. If $f_1(x), \dots, f_n(x)$ are objectives expressing the values of the criteria being used, then for each of them – subject to its impact upon investment efficiency – we choose a positive weighting factor λ_i . The procedure of weighting criteria (objectives) $f_1(x), \dots, f_n(x)$ consists in replacing them by one and only one criterion (objective) $f(x) = \lambda_1 \cdot f_1(x) + \dots + \lambda_n \cdot f_n(x)$ (Tchernorutsky I.G., 2001, p. 34-40).

However, for the purpose of managing the risks of an innovation program such reduction turns out to be practically impossible, therefore in the process of optimization we have to deal with a *vector* efficiency function

(*multi-criteria*). At the same time the permissible region M can change during optimization. More than that: its purposeful change is the substance of the process of optimization for this class of problems.

Since the laws of possible changes in the permissible region M are normally defined by a system of models, the approach to optimization problems I am describing here is called *system approach*. Within the framework of the system approach, the change of limits defining the permissible region in the space of individual parameters takes place as a result of a sequence of solutions we choose from a discrete set of possible solutions, where this set of solutions at the beginning of the optimization process can be defined incompletely and is being enlarged during the development and implementation of the innovation program.

One of very characteristic formalized statements of the problem of system optimization is the 2-criteria analysis. Let us suppose that by choosing the values of these criteria we can uniquely define the appropriate solution. In other words, the desired solution is being sought directly in the space K of optimization criteria that we will denote x_1 and x_2 .

The solution process begins when in the defined space K we choose a point A_o with coordinates a_o, b_o — the desired solution of the problem. Then we build initial constraints $F_1^{(o)}(x_1, x_2) \geq 0, \dots, F_n^{(o)}(x_1, x_2) \geq 0$ which define the initial permissible region P_o . By a direct check we define whether point A_o belongs to region P_o . In the former case, theoretically, we can use the conventional (classical) procedure of optimization by either one of the x_1, x_2 , criteria or by their combinations.

With the system approach, however, a much different method is used, namely: in accordance with model M at a higher level regulating the choice of criteria, point A_o is taken out of permissible region P_o after that we single out the constraints which do not hold for point A_o (in this case those will be $F_3^{(o)}$ and $F_4^{(o)}$). Turning to models M_3 and M_4 , which lay down these constraints, we consider — in the dialog mode — the solutions that can change the appropriate constraints in the desired direction (if possible). The "desired" direction in this case is considered to be the one which decreases the absolute value of negative residuals $F_i^{(o)}(a_o, b_o)$ (in the case under consideration it is $F_3^{(o)}(a_o, b_o)$ and $F_4^{(o)}(a_o, b_o)$).

Here we should bear in mind that in many cases the F_i constraints turn out to be interrelated, so the change of one of them leads to a change in a certain number of other constraints. The control of the solution choice needed to change the constraints is defined here by the minimization of a penalty function $g_o(a_o, b_o)$. For this penalty function the maximum absolute

value of negative residuals $\lambda_i F_i^{(0)}(a_0, b_0)$ is usually chosen (where λ_i – certain positive weight coefficients). If there are no such residuals, then, by definition, $g_0(a_0, b_0) = 0$. As a result of such control, there emerges a range of solutions $R_1 \dots, R_m$, each leading to the decrease of the penalty function value that we shall denote $g_m(a_0, b_0)$ after m solution.

Each of the accepted solutions - by changing the constraints - brings about the appropriate change in the permissible region. Let us consider two of such changes: the first one changes limits $F_3^{(0)}, F_2^{(0)}$, replacing them, respectively, by limits $F_3^{(1)}, F_2^{(1)}$; the second one affects only one constraint $F_4^{(0)}$ replacing it by constraint $F_4^{(1)}$. The resulting permissible region P_2 is limited by lines $F_1^{(0)}, F_2^{(1)}, F_3^{(1)}, F_4^{(1)}$, while the corresponding penalty function value is equal to $g_2(a_0, b_0)$. Advance choice of the final permissible region is impossible due to the fact that the sequence of regions $P_0, P_1 \dots$ cannot be ordered by embedding. In addition to this, the outstanding complexity of making new limits does not allow us to do it beforehand, because too much unnecessary work would be required to be done to change insignificant constraints. If $g_2(a_0, b_0) \neq 0$ and there are no solutions leading to further decrease in the value of the penalty function, then we are returned to the higher model M that controls the choice of the desired solution $A(a, b)$. By successive solutions D_1, D_2, \dots, D_k to change the initial solution of the problem $A_0(a_0, b_0)$ it is replaced by $A_1(a_1, b_1), \dots, A_k(a_k, b_k)$ till one of the next points $A_k(a_k, b_k)$ finds itself within the permissible region ($k = 1$). Solutions for change are chosen from the allowable set of solutions with the aim of minimizing the penalty function. This procedure seems to be very close to the classical optimization apart from the fact that steps are chosen not arbitrarily but in compliance with the permitted (by model M) solutions. After point A_k gets into the final permissible region P_m we can use an additional optimization procedure by various combinations of criteria x_1 and x_2 within this permissible region. This procedure differs from the classical one by the only fact that the choice of optimization steps is not arbitrary but is controlled by the higher level model M . If further improvement of the chosen criterion is hindered by certain limitations which we can change in the desired direction, then the optimization process can be continued through the inclusion of successive limitation-change solutions into it. The most important characteristic of system optimization retained in all approaches to the problem is - apart from multi-criteriality and a possibility to change the permissible region - the interaction of models on different levels. In this case, as part of structural analysis, this is system interaction: of the risk system composed of risk-factors, and of the

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

system of implementation of the regional innovation program – by a model on the M level. A single-valued solution of the problem - through the choice of the values of all optimization criteria - cannot be used here for the purposes of substantiation of the regional innovation program risk management model, because there is no uniqueness to the solution of this problem. The space where the solution is being sought, may have other coordinates in addition to the ones matching optimization criteria. The optimization procedure described above becomes complicated due to the fact that points $A_i (a_i, b_i)$ are replaced by hyperplanes – i.e. stable investment zones. Definition of the penalty function becomes more complicated too: we can take as this function, for instance, the distance between a chosen hyperplane and the next permissible region in the space with defined contractions (stretchings) along the axes corresponding to optimization criteria – change factors for the limiting values of the sustainability model.

The assessment of risks' (risk-factors') impact upon the efficiency of the innovation program has been done on the basis of a number of integral indexes, such as: net present value (NPV_T), profitability index (PI_T^d), internal rate of return (IRR), payback period (PP_T^d). Efficiency indicator's sensitivity to the change of risk-factors has been assessed by defining the indicator's elasticity for this specific factor. Let us denote the risk-factors by q_1, \dots, q_n ; their values we can obtain from the $NPV(q_1, q_2, q_3, \dots, q_n)$ formula ≥ 0 .

Regional innovation program sustainability model.

The model of sustainability of a region's innovation program can be defined as an assembly of risk-factor value sets $q_1, q_2, q_3, \dots, q_n$, satisfying the system of inequalities:

$$NPV(q_1) \geq 0; NPV(q_2) \geq 0; NPV(q_3) \geq 0; \dots; NPV(q_n) \geq 0.$$

If conditions applied to the value of the NPV indicator are met, then the values of indicators PI_T^d , IRR, PP_T^d will change accordingly.

Consider building a sustainability zone for an innovation program in a three-dimensional space with, for instance, four risk-factors affecting the situation.

- I. Define the maximum value by which the impacting risk-factors can increase.
- II. Then define how the sustainability zone of an innovation project changes if during the implementation of the innovations the desired rate of return on capital for an investor (r) changes.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

I. Now assume that the results of the innovation program changed because:

- the return on capital changed by several % ($-q_1$);
- the investment capital (IC_{1t}) increased by several % (q_2);
- the investment capital (IC_{2t}) increased by several % (q_3);

Calculate the factor limiting values with which the innovation program will have a cumulative break-even point.

Defining the limiting value of the return on capital change (q_1)

In a situation when the innovation program will have the cumulative break-even point, i.e. when the NPV will be equal to 0,

$$NPV = -\sum_{t=0}^T \frac{IC_t}{(1+r)^t} + \sum_{t=1}^T \frac{CFi_t - CFo_t}{(1+r)^t} \quad (1)$$

Let us equate expression (1) to 0.

To find the limiting value of the change of return we transform formula (1) by substituting the changes of return (q_1) into it (2):

$$\sum_{t=1}^T \frac{CF_t \left(1 + \frac{q_1}{100}\right)}{(1+r)^t} - \sum_{t=0}^T \frac{IC_t}{(1+r)^t} = 0 \quad (2)$$

By making the transformations we obtain the q_1 (3):

$$q_1 = \left[1 - \left(\frac{\sum_{t=0}^T \frac{IC_t}{(1+r)^t}}{\sum_{t=1}^T \frac{CF_t}{(1+r)^t}} \right) \right] * 100 \quad (3)$$

The resulting formula can be further simplified and the q_1 (4) calculated:

$$q_1 = \left(1 - \frac{DIC_t}{PV}\right) * 100 \tag{4}$$

Defining the limiting value of the change of equipment cost (q₂)

For this we transform formula (1) by substituting the capital investment change (q₂) into it, and then calculate the limiting value of the change of investment cost (IC_{1t}) of the innovation program (5):

$$q_2 = \frac{PV - IC_t}{IC_t} * 100 = \frac{NPV}{IC_t} * 100 \tag{5}$$

Defining the limiting value of the change of the equipment installation cost (q₃)

For this we transform formula (5) by substituting the capital investment change (q₃) into it, and then calculate the limiting value of the change of investment cost (IC_{2t}) of the innovation program (6):

$$q_3 = \frac{PV - IC_t}{IC_{2t}} * 100 = \frac{NPV}{IC_{2t}} * 100 \tag{6}$$

The results of the calculation are presented in Table 1.

Table 1. Impact of the limiting values of factor changes upon the efficiency indicators of an innovation project

Formation of the sustainability zone for a region's innovation program

The practical implementation of the theory of system optimization of risk management is done by the example of the assessment of risks of a particular regional innovation program.

Defining sustainability of the innovation program using specific data, such as:

IC = 90 thousand currency units; CF_{t1}.....CF_{t6}: 10, 20, 30, 30, 40, 51 thousand currency units; project implementation period T = 6 years, calculation time-step t = 1 year.

1. We define the formula of discount rate change (r) by extrapolation (see the text of the program).

2. We shape the sustainability zone for the innovation program using four risk-factors: cash flow - CF_t; capital investment - IC_{1t}, capital investment - IC_{2t}, discount rate - r.

(Carried out in the mathematical modelling software package MATHCAD).

Implementation program:

$$t := 0..6$$

$$CI := 900000$$

$$D := \begin{bmatrix} 0 \\ 10000 \\ 20000 \\ 30000 \\ 30000 \\ 40000 \\ 51000 \end{bmatrix},$$

$$T := 6$$

$$e(t) := 0.1 + 0.01t^2 + 0.05 \ln(t + 1)$$

$$NPV(t) := \sum_{k=0}^T D_k \cdot \frac{1}{(1 + e(t))^k} - CI$$

$$x := 0,$$

$$t := 0..6,$$

$$CI := 90000$$

**Proceedings of the 8th International Conference on Applied Economics

As a result, we have a model of innovation program of a region, in the process of whose implementation the discount rate (r) changes every year.

On Picture 1 you can see 12 models of regional innovation program sustainability consolidated into one image: lower part – 7 models – is the domain of efficiency (inside) the innovation program of the region; upper part of the image – the domain where this innovation program is inefficient (it is added here to make our study more comprehensive).

The analysis carried out by the author has allowed her to define the innovation program of a region as a complex dynamic system whose risk management is possible if the method of sustainability assessment is used; the method is based on the risk management model mathematically substantiated by S.Pontryagin.

Figure A. Sustainability zone of an innovation project

$$x = 0.25$$

$$Tirr (s, a, q) = \text{root} (NPV (x, s, a, q), x)$$

$$Tirr (0,0,0) = 6.281$$

$$IRR (s, a, q) := e(Tirr (s, a, q))$$

$$IRR (0,0,0) = 0.594$$

Conclusions

The study offers the results of application of the system optimization method to the task of shaping an uncertainty/risk assessment model for the management of a region's innovation program; the method is based on the procedure that assumes defining the limiting values of the factors that bring the design value of a corresponding investment efficiency criterion to its critical limit while solving direct problems. As a result of my study, I propose the model of a regional innovation program's sustainability zone under risk and uncertainty, using the MATHCAT software.

The assessment of risks' (risk-factors') impact upon the efficiency of the innovation program has been done on the basis of a number of integral indexes, such as: net present value (NPVT), profitability index (PITd), internal rate of return (IRR), payback period (PPTd). Efficiency indicator's sensitivity to the change of risk-factors has been assessed by defining the indicator's elasticity for this specific factor. The model of sustainability of a regional innovation program is defined as an assembly of value sets of risk factors $q_1, q_2, q_3, \dots, q_n$, satisfying the system of inequalities:

$$NPV(q_1) \geq 0; NPV(q_2) \geq 0; NPV(q_3) \geq 0; \dots; NPV(q_n) \geq 0.$$

Most generally, point sets of arbitrary form may be involved instead of hyperplanes. Problem formulations are possible where criteria values in these sets are defined ambiguously, while for the definition of more or less desirable solutions we have to define appropriate weight functions in these sets (by a model of the higher level M).

The most important characteristic of system optimization retained in all approaches to the problem is - apart from multi-criteriality and a possibility to change the permissible region - the interaction of models on different levels. In this case, as part of structural analysis, this is system interaction: the risk system composed of risk-factors, and the system of implementation of the regional innovation program - by a model on the M level.

When considering a large number of risks (risk-factors) impacting the efficiency of a region's innovation program and subject to analysis and control, a hyperplane taken in the three-dimensional space tends to a one-sheet hyperboloid.

**The Impact of Capital Ratio on Lending of EU
Banks – the Role of Bank Specialization
and Capitalization***

JEL Classification: *E32; G21; G28; G32*

Keywords: *loan supply; capital ratio; procyclicality*

Abstract: In this paper we aim to find out whether bank specialization and bank capitalization affect the relationship between bank loan growth and bank capital ratio, both in expansions and in contractions. We hypothesize that the impact of bank capital on lending is relatively strong in cooperative banks and savings banks. We also expect that this effect is nonlinear, and is stronger in “low” capital banks than in “high” capital banks. To test our hypotheses we apply two-step GMM robust estimator (Blundell & Bond, 1998) for data spanning the years 1996 – 2011

on individual banks available in the Bankscope database. Our analysis shows that lending of poorly capitalized banks is more affected by capital ratio than lending of well capitalized banks. Loan growth of cooperative and savings banks is more capital constrained than lending of commercial banks. Capital matters for the lending activity in contractions only in the case of savings and “low” capital banks.

Introduction

The size of the effect of changes in bank capital on the extension of bank credit has been one of the most important questions of the crisis, due to role that banks play in the economy. In the aftermath of the 2007/8 financial turmoil, Basel Committee proposed significant changes to previously accepted capital standards. The set of new rules has been named Basel III. It covers substantial increases in regulatory capital ratios and in the quality of bank capital (BIS, FSB & IMF, 2011; BIS, 2010, 2011). These new standards are now being implemented in EU, due to formal acceptance of its rules in directive¹ and in regulation² in 2013. As the EU market is a definitely more banking sector oriented economy, it is important to extend our knowledge on the importance of bank capital for bank lending.

Although the magnitude of the effect of bank capital on bank lending in the 2007 financial crisis seemed to be a very salient question for practitioners and researchers, few recent estimates of this effect exist. These estimates are usually focused on the US banks (Beatty and Liao, 2011; Berrospide and Edge, 2010; Carlson, Shan & Warusawitharana Carlson). Some papers investigate a sample of both EU and US banks (Gambacorta and Marquez-Ibanez, 2011). Several papers focus on selected single countries in the EU (e.g UK: Mora & Logan, 2011 and Bridges Gregory, Nielsen, Pezzini, Radia & Spaltro, 2014; France: Labonne & Lame, 2014). The main message from these studies is that bank capital does indeed affect bank lending, though this impact is diversified. In a recent study Olszak, Pipień, Roszkowska & Kowalska (2014 b) focus on large EU banks, and test whether this diversity may be attributed to income smoothing, procyclicality of loan loss provisions, regulations and supervision. They find that

¹ See DIRECTIVE 2013/36/EU OF THE EUROPEAN PARLIAMENT AND OF THE COUNCIL of 26 June 2013 on access to the activity of credit institutions and the prudential supervision of credit institutions and investment firms, amending Directive 2002/87/EC and repealing Directives 2006/48/EC and 2006/49/EC ((L 176).

² REGULATION (EU) No 575/2013 OF THE EUROPEAN PARLIAMENT AND OF THE COUNCIL of 26 June 2013 on prudential requirements for credit institutions and investment firms and amending Regulation (EU) No 648/2012 (L 176).

loan growth of banks that have more procyclical loan loss provisions and that do not engage in income smoothing is more sensitive to capital ratios. They also find that more restrictive regulations and more stringent official supervision reduce the magnitude of the effect of capital ratio on bank lending.

Our study makes one significant contribution relative to the literature. We extend analysis of Olszak et al. (2014b) on the effects of capital ratios on loan growth of the EU single market, by analysis of two important research areas. The first consists in looking at potential diversity of association between loan growth and capital ratio in banks differing in their specialization. The other area is related to nonlinear effects of capital ratios on lending, which was tested in the US banks (see Carlson et al., 2013), but not in the EU banks. In this area we ask whether the level of capital ratio is important for the effects of bank capital on lending activity, and how important is it?

To test our hypotheses we apply the two-step GMM robust estimator (Blundell & Bond, 1998) for data spanning the years 1996 – 2011 on individual banks available in the Bankscope database

The rest of the paper is organized as follows. Section 2 develops our hypotheses. In Section 3 we describe our sample and research design. We discuss results and supplemental analyses in Section 4. Section 5 concludes our work.

Hypotheses development

The role of bank specialization for procyclicality of bank capital has not been formally tested thus far.³ Some evidence in this respect, however, can be found in a study of Gambacorta & Mistrulli (2004), who analyzed the impact of bank capital on lending of cooperative banks and commercial banks. They suggest that bank capital channel may be stronger for cooperative banks because of two features of those banks' activity. The first is the fact that cooperative banks' balance sheets contain a larger percentage of long-term loans (which means that balance sheet maturity transformation gap is larger, exposing them to greater interest rate risk), while their bonds issues are lower. The second explanation for the greater effect of the bank capital channel for these banks could be the local activity of these banks and thus little use of derivatives to shield the maturity transformation gap.

³ Specialisation is an important determinant of procyclicality of loan loss provisions (see Olszak et al, 2014a).

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

With these characteristics cooperative banks bear a higher cost when interest rates are raised and obtain a higher gain in the opposite case. However, it is also possible that the close relationship of cooperative banks with their members, makes them more resilient to business cycle fluctuations, and therefore it is possible they will lend to their borrowers irrespective of the macroeconomic conditions. In contrast, commercial banks may be more responsive to external financing conditions, and therefore may be responsive to business cycle fluctuations in lending activity. In particular, in the case of commercial banks, the association between loan growth and capital ratio in contractions may be positive, implying that they are capital constrained.

Following the above we hypothesize that:

H1. Commercial banks lending is less affected by capital ratios than cooperative banks lending.

The only sample of banks for which the effect of bank capital on lending has not been empirically tested thus far is the savings banks category. The specific feature of their activity is deposit collection and loan extension to customers –which resembles the business model of cooperative banks, especially due to the potentially large maturity transformation gap in these banks. Consequently, in the same line as cooperative banks, savings banks may be prone to interest rate risk, and thus their lending could be strongly related to capital ratios. But unlike cooperative banks, the customers of savings banks do not have so close ties with the bank. Moreover, savings banks are not operating on local markets. Therefore, they may respond to contractions by reducing their lending. And it is possible, that the association between capital and lending in contractions will be positive.

As for the role of the level of capital ratio for the effects of the capital ratio on loan growth there are at least two possible explanations. On the one hand, Peydró (2010) suggests that due to the correlation between banks and poor quality borrowers on the cross-section, banks with lower capital may lend more on average to firms with higher risk. In contractions or during crisis times financially weaker borrowers, (e.g. companies with low level of internal finance) may need more bank financing, and thus increase the demand for credit. If these borrowers are matched with poorly capitalized banks, then at the bank level the association between capital and lending would be weak or counterintuitive, as these weaker banks are facing higher credit demand. However, as Peydró suggests, this does not mean that bank

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

capital is not crucial, it only shows that an analysis at the bank and borrower level may yield biased estimates.

On the other hand, in the theoretical setting, Valencia (2008) shows that banks seek to keep some precautionary level of capital that serves them as a smoothing mechanism to avert disruptions in the supply of credit when the small shocks occur. Therefore the question is whether the association between capital ratios and loan growth is larger when the capital buffer⁴ – i.e. the difference between the actual bank capital and the minimum capital (e.g. capital adequacy ratio or internal capital requirement) is small, and whether the relationship is weak when the buffer is high.

Some previous empirical evidence suggests that when the capital ratio of a bank is closer to its minimum requirement then banks tend to reduce their lending (Gambacorta and Mistrulli, 2004; Kishan and Opiela, 2006; Carlson et al., 2013). Gambacorta and Mistrulli (2004) show that Italian banks with more capital relative to minimum requirements tend to be less responsive in their lending extension to negative monetary policy shock or cyclical downturn. Kishan and Opiela (2006) investigate the effects of expansionary and contractionary monetary policy on lending of low-capital and high-capital banks. They find that monetary policy has asymmetric impact on lending, depending on whether the bank belongs to either low-capital or high-capital sample and on the type of monetary policy applied. Their results show the low-capital banks are adversely affected by contractionary policy, but expansionary policy is not effective in stimulating the loan growth of low-capital banks.

In a recent paper Carlson et al. (2013) test the hypothesis that the association between capital ratios and loan growth is nonlinear. To test this explanation, they interact capital ratio with three indicator variables: “low” capital, “medium” capital and “high” capital banks. Their study provides strong empirical evidence of a nonlinear effect. While they find that capital ratio has a positive relationship with loan growth, the effect is large and statistically significant when capital ratio is closer to the regulatory minimum requirement and becomes smaller and less significant as capital ratio increases.

Considering the results of previous studies we put forward our second hypothesis below.

⁴ More on the role of a bank’s capital buffer on the risk-taking and therefore on the lending activity of the bank can be found in Borio and Zhu (2012).

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

H2: The relationship between capital ratio and loan growth of EU banks is nonlinear.

More specifically, we expect that:

H2.1. The association between capital ratio and loan growth of EU banks is larger when the capital ratio is closer to its minimum requirement.

Beatty and Liao (2011) find that effect of the capital ratio on loan growth is strengthened during recessionary periods in the sample of publicly traded US banks. This result is further supported by Carlson et al. (2013), who found that the effect of three types of capital ratios on loan growth rate was stronger in lending contraction relative to lending expansion. This leads us to our third hypothesis that:

H.3. The association between loan growth and the capital ratio is stronger in contraction in the case of “low” capital banks.

Data and research methodology

Data

We use pooled cross-section and time series data of individual banks' balance sheet items and profit and loss accounts from 27 EU countries and country-specific macroeconomic indicators for these countries, over a period from 1996 to 2011. The balance sheet and profit and loss account data are taken from unconsolidated financials available in the Bankscope database, whereas the macroeconomic data were accessed from the EURO-STAT and the IMF web pages. We exclude from our sample outlier banks by eliminating the extreme bank-specific observations when a given variable adopts extreme values. Since most of these institutions are located in Ireland, the number of countries included in the final sample drops to 26. Based on this selection strategy, the number of banks included in our sample is 2523 (27359 observations and 26 countries).

Methodology of research

The most problematic issue in the measurement of the impact of bank capital on loan extension is the identification of supply and demand factors,

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

which affect lending activity. In particular, during recessionary periods, not only credit supply (due to bank capital and liquidity problems) may decrease, but also credit demand of households and firms may decline. This makes difficult any identification of bank capital effects on lending in downturns.

Several approaches have been used in the literature to take account of both supply side and demand side determinants of bank lending. The *traditional approach* is to take into account economic conditions linked to loan demand such as inflation, gross domestic product growth or unemployment rate (see e.g. Gambacorta & Mistrulli, 2004; Berrospide & Edge, 2010; Beatty & Liao, 2011). Other papers use regional variations of bank health and economic conditions to differentiate between supply and demand effects (Hancock & Wilcox, 1998).

The second approach consists in the application of data extracted from the national central *bank lending surveys* (Blaes, 2011; Del Giovane, Eramo & Nobili; 2011, Bassett et al., 2014 and Labonne & Lame, 2014). In this literature, researches combine bank-level data with individual responses to the lending survey and study the dynamics of credit in Germany (Blaes, 2011), Italy (Del Giovane et al., 2011), US (Bassett, Chosak, Driscoll & Zakrajasek, 2014) and French (Labonne & Lame, 2014). These studies reveal significant contribution of bank lending surveys in disentangling credit supply shocks from demand shocks, especially during the financial crisis.

The third solution is to use a *quasi experiment* – which requires having data on banks affected by shock which had not been generated by a market where the bank is operating. Such an approach has been applied by Peek & Rosengren (1997) who analyzed the effects of capital shocks on the lending of the branches and subsidiaries of Japanese banks located in the United States. By focusing on the transmission of the effects of Japanese stock market losses via the actions of Japanese bank branches and subsidiaries in the United States, Peek & Rosengren were able to isolate the credit supply effects of a fall in bank capital. In a more contemporary study Mora & Logan (2011) use losses on UK banks' loan to non-UK residents (an external shock) and see how this affected lending to UK residents.

The empirical models that addressed the question of whether a bank-capital induced credit crunch was hindering the recovery were developed in the early- and mid-1990s in the US (see e.g. Bernanke & Lown, 1991; Hancock & Wilcox, 1994a,b; 1997; 1998; Peek & Rosengren, 1995). In our study we apply contemporary adoptions of those models available in sever-

al studies (Berrospide & Edge, 2010; Beatty & Liao, 2011; Carlson et al., 2013; Labonne & Lame, 2014; Bridges et al., 2014 and Olszak et al., 2014b). Our basic model is given by equation (1):

$$\Delta Loan_{i,t} = \beta_1 + \beta_2 Contraction + \beta_2 CAP_{i,t} + \beta_3 Contraction * CAP_{i,t} + \beta_4 DEP/TA_{i,t} + \beta_5 INTERBANK_{i,t} + \beta_6 \Delta CAP_{i,t} + \beta_7 QLP_{i,t} + \beta_8 size + \beta_9 \Delta UNEMPL_{j,t} + \beta_{10} \sum_{j=1}^{27} Country_j + \beta_{11} \sum_{t=1996}^{2011} T_t \vartheta_{i,t} + \varepsilon_t \quad (1)$$

where:

i- the number of the bank;

j-the number of country;

t- the number of observation for the i-th bank;

$\Delta Loan$ – real annual loan growth rate;

CAP – capital ratio, i.e. equity capital divided by total assets;

DEP/TA – deposits from nonfinancial customers divided by total assets;

$INTERBANK$ – a measure of interbank market activity; it equals bank loans extended to other banks divided by deposits from banks;

$DEPBANKS$ – deposits from banks divided by total assets;

ΔCAP – annual change in capital ratio;

QLP – is quality of lending portfolio; it equals loan loss provisions divided by average loans;

$size$ – logarithm of assets;

$\Delta UNEMPL$ - annual change in unemployment rate.

In our research we focus on only one capital ratio measured as the equity capital divided by total assets. We do not include other types of capital ratios, such as capital adequacy ratio or Tier 1 capital ratio due to the large number of missing data on these ratios in the Bankscope database.

Annual change in unemployment rate is our measure of demand for loans (Bikker and Metzmakers, 2005; Dell' Ariccia, Igan & Laeven, 2012).

Elements $\sum_{j=1}^{27} Country_j$ and $\beta_{11} \sum_{t=1996}^{2011} T_t$ are a set of country and time dummy variables ϑ are unobservable bank-specific effects that are not constant over time but vary across banks. Finally, ε is a white-noise error term.

In Table 1 we present all variables applied in our econometric model with expected impact they have on loan growth. We predict a negative coefficient on $Contraction$ if loan supply declines during contractions for reasons other than capital and liquidity constraints (as do Beatty & Liao,

2011, p. 7).

To test our first hypothesis we conduct separate regressions for commercial banks, cooperative banks and savings banks.

To test our second hypothesis we divide our banks into three subsamples: low capital, medium capital and high capital. The low capital (henceforth low cap₃₀) bank is a bank that has the capital ratio below 30th percentile of the distribution. The medium capital bank (henceforth medium cap₄₀) is a bank that has the capital ratio between the 30th and 70th percentile, and the high capital bank (henceforth high cap₃₀) has the capital ratio above the 70th percentile. In order to check if the results are robust to different thresholds, we additionally run separate regressions for 20th percentile (high capital), between 20th and 60th (medium capital) and for above 60th percentile (high capital).

To take account of the impact of the capital ratio on loan growth in contractionary periods we include interaction term between CAP and Contraction. We expect positive association between loan growth and this interaction term only when banks feel capital constrained in contractions, and therefore do not increase their lending.

Contraction is one of our key variables. Due to the fact that there is no one dataset including information on business cycle expansions and contractions in all EU countries, we have to resort to our own identification procedure. In this procedure we follow Lenart & Pipień (2013) approach, and apply dataset available in a study by Olszak et al. (2014b, p. 41).

Table 1. Variables description and expected signs in the regressions

Variable name	Expected sign	Basic argument
Δloan		
Contraction	-	A negative coefficient on Contraction is predicted if loan supply declines during contractions for reasons other than capital and liquidity constraints
ContractionxCAP	+/- +	A positive sign is expected if banks' loan growth is constrained by capital in contractions, a negative sign is expected otherwise. A positive sign is expected if loan growth is constrained by capital ratio. That is banks with higher capital ratio will extend more loans.
CAP		

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

DEP/TA	+	Banks which have more stable funding (deposits) relative to loans should be able to extend loans.
INTERBANK	+/-	A positive sign is expected if interbank deposits boost liquidity of a bank, and make lending easier
Δ CAP	-	To increase capital ratio a bank must either increase its capital (without changes in risk weighted assets) or decrease risky loans (without change in capital).
QLP	-	The higher the share of loan loss provisions in bank loans the lower the loan growth
Size	+/-	Large banks may benefit from too-big-to-fail position and thus might isolate better adverse shocks (a positive coefficient).
Δ UNEMPL	-	The higher the unemployment rate the lower is the demand for loans, and thus the loan growth is reduced

Source: own work.

Our econometric model involves explanatory variables that may be endogenous. This means that these variables are correlated with the error terms, both current and lagged. Also one may observe heteroskedasticity effects and autocorrelation within individuals. Therefore, we apply an approach that involves instrumental variables. In order to limit the possible estimation bias we consider the system of generalized method of moments (GMM) developed by Arellano & Bond (1991), and further developed by Blundell & Bond (1998). We control for the potential endogeneity of bank specific variables, i.e. CAP, DEP/TA, INTERBANK, Δ CAP and QLP in the two step system GMM estimation procedure, by the inclusion of up to eight lags of explanatory variables as instruments. The UNEMPL, as well as the country and the time dummy variables are the only variables considered exogenous. The GMM estimator is efficient and consistent if the models are not subject to serial correlation of order two and the instruments are not proliferated. Therefore we apply the test verifying the hypothesis of absence of second-order serial correlation in the first difference residuals (ar2). We also use the Hansen's J statistic for overidentifying restrictions, which tests the overall validity of the instruments tests (see Roodman, 2009, for more details).

Results

Results using full sample of banks are given in table 2. We find evidence in favour of capital ratios impacting loan growth, as the association between loan growth and capital ratio is positive and statistically significant in the full sample of banks. Our estimates suggest that a 1 percentage point increase in capital ratio results in bank loan growth of 1.01%. If we take account of bank specialization, we find that cooperative and savings banks' lending is a little bit more capital constrained by the capital ratio than lending of commercial banks. This gives some empirical support to our first hypothesis (H1).

Our results, which appear in table 2 provide strong evidence of a non-linear effect and thus give support to hypothesis H2. When capital ratio of a bank is below the 30th percentile, our estimates suggest that a 1 percentage point increase in capital ratio raises bank loan growth by 2.34 percentage points. When the capital ratio is above the 70th percentile of its distribution, however, the estimates suggest that capital ratio has a much more modest impact on bank lending. In this sample of banks the association between loan growth and bank capital ratio is 0.62, which means that a 1 percentage point increase in capital ratio results in 0.62% increase in loan growth.

As for the impact of bank capital on lending in contractions two types of banks seem to be capital constrained. The first group consists of savings banks. In this sample the impact of the capital ratio is positive and statistically significant, but relatively weak. The other sample includes "low capital banks, as our results suggest that the effect of capital ratio on lending in contractions is positive and strongest only in the case of "low" capital banks.

With respect to the other variables, we find that liquidity stemming from access to stable financing (measured with DEP/TA) has economically and statistically significant impact on the lending activity of all types of banks. Having said this we must stress the fact that the impact of liquidity constraints is definitely weaker than the impact of capital ratios, as the regression coefficients on DEP/TA are definitely lower than coefficients on CAP.

Relatively poor performance of loans, as measured by loan loss provisions over average loans (QLP), but for savings banks, tends to be associated with slower loan growth rates.

Size also matters for the lending capacity of banks. On average, banks with larger assets extend more new loans, as the regression coefficient on size is positive and statistically significant. The estimated effect is strongest

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

in the case of “low” capital banks. In this subsample a 1 percentage increase in the size variable raises the lending by 5%. Generally, our findings support the view that big banks should be less prone to adjusting their credit portfolio in the event of external shocks (such as monetary policy changes or crises).

We also find that loan growth is higher when unemployment rate is higher all types of banks. This seems to lend support to view that in the case of most banks, supply factors are more important for loan growth, than demand effects.

The model is given by equation (1). The symbols have the following meaning: Δ loan – annual loan growth rate (real); Contraction - Dummy equal to one in contractions and 0 otherwise; CAP - capital ratio, i.e. equity capital to total assets; ContractionxCAP - Interaction between contraction and capital ratio (CAP); Δ CAP – annual change in capital ratio; DEPBANKS - Deposits from banks to total assets; LIQGAP - Loans less Total customer deposits less Deposits from banks divided by Loans; size - logarithm of total assets; QLP - Loan loss provisions divided by average loans ; Δ UNEMPL – change in annual unemployment rate. Coefficients for the country and time dummies are not reported. The models have been estimated using the GMM estimator with robust standard errors. The p-val denotes significance levels. Values in bold denote statistically significant results. T-statistics are given in brackets. Data range 1996-2011.

Conclusions

This paper investigates the existence of cross-sectional differences in the response of bank lending to bank capital in the EU, both in expansions and in contractions. Our analysis is conducted separately for banks differing in specialization and levels of capital ratio. We find that cooperative and savings banks' lending is a little bit more capital constrained by the capital ratio than lending of commercial banks. We also find that "high" capital banks can better shield their lending from contractions as well as are less capital constrained in their credit extension in expansions than "low" capital banks. The lending of poorly capitalized banks is more affected by the capital ratio than lending of well capitalized banks. Capital matters for the lending activity in contractions only in the case of savings and "low" capital banks.

All in all, these findings indicate that bank capital is a relevant determinant of lending activity. As we find that lending of well capitalized banks is less affected to changes in capital ratio, we give empirical support to contemporary changes in capital regulations exemplified in the Basel III standards.

**Economic Consequences of the Adoption of the
International Financial Reporting
Standards: Evidences in the Research
Literature***

JEL Classification: *G14; M41*

Keywords: *Economic consequences; International Financial Reporting Standards; listed entities; quality of financial information; stakeholders*

Abstract: Along with the economic globalization, the international accounting regulation bodies faced the need to issue internationally accepted global accounting standards. The effect was the issuance and the widespread of the International Financial Reporting Standards (IFRS). At European level, the IFRS gained legitimacy in 2002, when the European Parliament and Council have decided that all European publicly traded entities must prepare their consolidated financial statements in accordance with IFRS starting with January 1st, 2005. The regulation from

2002 on the application of the international standards in EU summarizes the benefits emerging from the adoption and use of IFRS, related to: a high degree of transparency and comparability of financial statements and, as consequence, an efficient functioning capital market. However, the achievement of these expected benefits is based on the assumption that the application of these standards contributes to the increase in the quality of accounting data reported in the financial statements. In this context, our main objective is to summarize, based on the research literature, the economic consequences that emerge from the publication of higher quality accounting data in accordance with IFRS.

Introduction

The contemporary features of the business environment influence the theory and the method of accountancy. Thereby, the need for worldwide financial reporting comparability arise in the context of the expansion of world trade, the spread of multinational corporations, the increasing role of global capital markets and the enhanced foreign direct investment.

In the past decades, the accounting regulating bodies have made efforts in order to address these new challenges and to provide accounting solutions for presenting the accounting information in a common language, understandable for cross-border investors and other stakeholders.

The application of the IFRS registered a continuous progress, from being very little used to becoming nowadays widespread at world level. The number of countries that adopt the international financial reporting standards is increasing, the national accounting regulators allowing or mandating the use of these standards for certain types of entities. According to the information published on the website of IFRS Foundation, today there are over 130 jurisdictions that use the IFRS.

At European level, IFRS widespread was favoured by the issuance of Regulation no. 1606/2002 of the European Parliament and of the Council of 19 July 2002 on the application of international accounting standards (EC, 2002). According to this Regulation, for each financial year starting on or after 1 January 2005, companies governed by the law of a Member State prepare their consolidated financial statements in conformity with the international financial reporting standards if, at their balance sheet date, their securities are admitted to trading on a regulated market of any Member State. Also, Member States have the possibility to allow or to require the use of IFRS for other types of entities (for the individual financial statements of listed entities, for the consolidated and/or individual financial statements of unlisted entities).

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

The Regulation no. 1606 from 2002 summarizes the benefits of adopting and using the international standards in the EU, regarding the fact that they ensure “a high degree of transparency and comparability of financial statements and hence an efficient functioning of the Community capital market and of the Internal Market” (EC, 2002, article 1).

The research literature conducted in the field of IFRS adoption is generous. Researchers measured the effects of the application of IFRS on accounting numbers (Neag, 2014, pp. 1787–1790; Hung & Subramanyam, 2007, pp. 623–657; Jaruga et al, 2007, pp. 67–78; Jermakowicz, 2004, pp. 51–70), tested the benefits emerging from the transition to IFRS (Armstrong et al., 2010, pp. 31–61; Schleicher et al., 2010, pp. 143–168), pointed out the limits of IFRS implementation (Street & Larson, 2004, pp. 1–29) or analyzed the impact of IFRS adoption on taxation (Păunescu, 2015, pp. 81–91). Another valuable stream of research is represented by the analysis of controlling tasks in the context of IFRS implementation (Roman et al., 2014, pp. 13–26; Mocanu, 2014, pp. 62–66). Researchers have also investigated the perception regarding the manifestation of accounting judgment and ethics in accounting in the process of IFRS application (Cernuşca & Balaciu, 2014, pp. 110–122).

Moreover, we ascertain an emphasis on the research designed to capture the effects on IFRS adoption on the quality of financial reporting, measured by means of value relevance (Filip & Raffournier, 2010, pp. 77–103), earnings management practices (Barth et al., 2008, pp. 467–498; Brad et al., 2014, pp. 871–876; Nichita, 2014, pp. 674–690) or accounting conservatism (Andre et al., 2013, pp. 1–43; Maşca, 2014, pp. 349–355).

The study of the quality of financial reporting subsequent to the adoption of IFRS is important. The expected benefits of the convergence process and of the adoption of the international standards are based on the premises that the application of IFRS contributes to the improvement of the quality of accounting data reported in the financial statements.

However, testing the effects of IFRS adoption on the quality of accounting data is necessary, but not enough; knowing whether IFRS contributed to enhanced accounting quality is not the end of the road. Further research needs to be done in order to investigate the consequences of the increased quality of the information presented in the financial statements (Păşcan, 2014).

In this context, the main objective of our paper is to analyze and summarize, based on the research literature, the economic consequences that

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

emerge from presenting and publishing qualitative accounting data in accordance with the international financial reporting standards.

The paper is structured as follows: next paragraph presents the research methodology; then, we present the pillars of improved accounting quality after the adoption of IFRS and discuss the main economic consequences of using the information in the financial reporting prepared in accordance with IFRS. Concluding remarks are presented at the end of the paper.

Methodology of the research

In order to answer to our stated objective, the research methodology employed in this study is mainly qualitative, based on bibliographic documentation. In order to identify and analyze the economic consequences that emerge from the improved quality of accounting data in the context of IFRS adoption, we have examined the databases containing research literature in the field of accountancy (such as Science Direct, JSTOR, Web of Science), using terms such as „economic consequences”, „IFRS adoption”, „accounting quality”; we have selected the papers that we consider to be relevant for the purpose of our study and formed a database containing theoretical and empirical papers that analyze the economic consequences of IFRS adoption. Aiming not to leave out valuable papers published in this area, we have analyzed the references of certain papers and searched for the papers that we considered fundamental for our field of interest (we have also considered the number of citations associated to the selected papers). Next, we have reviewed the selected papers and summarized the economic consequences of IFRS adoption. We outline a typology of this economic consequences, according to the context of the adoption of IFRS (mandatory of voluntary) and to the category of stakeholders that benefit from analyzing qualitative accounting information prepared in accordance with the international financial reporting standards.

The economic consequences of the adoption of the International Financial Reporting Standards – a literature review

Some features associated to the international financial reporting standards could determine the enhancement of the accounting quality after the application of these standards and regardless of the incidence of country-specific institutional factors. We present the pillars of improved accounting quality after the adoption of IFRS, in order to explain why we could expect

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

higher-quality accounting information in the context of the application of these standards.

The IFRSs are principle-based standards

It is the objective of IFRS Foundation to develop a single set of high quality, understandable, enforceable and globally accepted financial reporting standards based upon *clearly articulated principles*.

With fewer pages and less detail compared to the rules-based standards (for example, the United States Generally Accepted Accounting Principles), the IFRSs still address all major accounting issues, from financial statement presentation to business combinations.

The IFRSs are referred as being principle-based standards because they provide general guidance for recognizing, measuring and presenting the elements in the financial statements. The accountants rely on the general principles stated in the IFRSs in order to guide their professional judgment.

The well-known scandals (Enron, WorldCom) could represent an example on how rigid rules can be manipulated in order to produce concealed accounting information. Being principle-based standards, the IFRSs could improve the quality of accounting information because they are more difficult to circumvent.

Also, relying on principles instead of rules, the IFRSs offer the opportunity to appeal to the professional judgment in order to properly reflect the economic reality, instead of struggling for achieving the compliance with the imposed rules.

The IFRSs allow evaluation methods that better reflect the financial position and performance

For example, the use of fair value could contribute to a more appropriate representation of the economic reality, compared to national accounting regulations. Accounting amounts reported using fair value measurement could improve the quality of accounting data since they are more useful to investors in making their investing decisions.

Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

The limitation of allowable accounting options

In order to faithfully reflect the financial position and performance of an entity, since 2001 the International Accounting Standards Board (IASB) aims to eliminate allowable accounting alternatives. Such an endeavour, directed toward reducing the number of allowed accounting options, represents a premise for improving the quality of accounting data following IFRS adoption, because it limits the earnings management practices, for example by restricting the possibilities to manipulate the earnings.

Ewert & Wagenhofer (2005) cited in Barth et al. (2008, pp. 467-498) find that accounting standards that limit the management opportunistic behaviour allow the determination of accounting income which better reflect the economic reality and, accordingly, are more qualitative.

Moreover, the quality of accounting data could be improved if, simultaneously with IFRS adoption, there would be changes in the financial reporting system, for example, a more rigorous enforcement (Barth et al., 2008, p. 468).

However, the research literature provides mixed evidence on the effects of IFRS on the quality of accounting data. The results of the research conducted in this field do not fully sustain the assumption that IFRS adoption determines the publication of more transparent, more comparable and, therefore, more qualitative financial reporting.

And, even if financial reporting practices of entities would become more transparent or more comparable following IFRS application, the economic consequences of such an improvement of accounting quality cannot be forehand known, nor is there any guarantee that favourable economic consequences will be recorded.

We argue that only knowing the economic consequences arising from the adoption of IFRS, analyzed according to different categories of users of financial reporting, could provide a fully understanding of the effects of international accounting convergence process.

The economic consequences are defined in the research literature as “effects of financial reporting on firm values and on the wealth of those who make or are affected by decisions based on accounting information” or „the impact of accounting reports on the decision-making behaviour of firms and their stakeholders” (Zeff, 1978 cited in Brüggemann et al., 2013, pp. 1-37).

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

Next, based on the study of the accounting literature, we analyze the economic consequences of increased quality of accounting data following IFRS adoption.

Brüggemann et al. (2013) have classified the economic consequences that emerge from the mandatory adoption of IFRS in relation with the stated objectives from EU Regulation from 2002 on the application of international accounting standards, as follows:

- a) financial reporting effects, regarding:
 - compliance with IFRS requirements and accounting choices under IFRS.
 - In our opinion, it is important to test these consequences, because they offer insight into the extent to which the adoption of IFRS facilitates the comparability of financial statements between countries.
 - accounting properties, such as earnings quality (expressed by means of earnings smoothing, conditional conservatism, discretionary accruals). Studying accounting properties has, among others, the role of indicating whether the objective regarding financial statement transparency is fulfilled after mandatory IFRS adoption.
 - value relevance, referring to the ability of information presented in the financial statements prepared in accordance to IFRS to capture the value of an entity;
- b) capital market effects, which could consist in:
 - increasing the liquidity of stock market;
 - decreasing the bid-ask spread;
 - decreasing the cost of equity capital;
 - increasing the equity investments by institutional investors;
 - decreasing the cost of public debt;
 - increasing the firm-level capital investment efficiency;
 - increasing the content of earnings announcements;
 - enhancing the quality of analysts' information environment;
- c) macroeconomic effects, such as the increase of foreign direct investment.

Ahmed *et al.* (2013, p. 1346) present the favourable economic consequences associated with mandatory IFRS adoption documented in the research literature, related to the improvements in analyst forecast accuracy, reduction in the cost of equity capital and positive price reactions to events suggesting an increase in the likelihood of mandatory IFRS adoption. But, contrasting with these findings, in the context of an empirical research conducted on 20 countries that adopted IFRS in 2005 relative to a benchmark group of firms from countries that did not adopt IFRS, Ahmed *et al.* (2013)

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

state that “improved accounting quality is unlikely to be an explanation for these favourable economic consequences”.

Aiming to test whether higher corporate performance is a consequence of better quality of financial information, (Martinez-Ferrero, 2014, pp. 49-88) also find that the increased quality of accounting information facilitates transparency, which in turn reduces the informational asymmetry and satisfies the information needs of investors and other stakeholders.

Amiram (2012, pp. 57–81) find that foreign equity portfolio investments increase in countries that adopt the IFRSs, and Moscardiello *et al.* (2014, pp. 63-82) observe positive consequences of mandatory adoption of IFRS on the cost of debt.

A valuable research direction was followed by Daske *et al.* (2013, pp. 495-547), which studied the economic consequences of the adoption of IFRS, by analyzing the heterogeneity among entities regarding the way of implementation of new standards. The surveyed entities were classified as “label adopters” (those which adopted the international standards merely in name, without making material changes to their reporting policies) and “serious adopters” (entities that adopted the international standards as part of a broader strategy to increase their commitment to transparency). Favourable economic consequences, related to increased liquidity and decreased cost of capital, were observed only in case on “serious adopters”.

Another research that propose to test the economic consequences of IFRS adoption in relation to the heterogeneity of analyzed entities was published by Christensen *et al.* (2007, pp. 341–379). The authors have studied the economic consequences of mandatory IFRS adoption in case of the entities from UK, starting from the premise that these consequences depend on whether entities perceive (or not) benefits from the process of IFRS adoption. Thus, mandatory IFRS adoption does not uniformly produce benefits for all entities, but generates winners and losers; the obligation to apply IFRS determines net benefits for entities that would have voluntarily decided to switch to IFRS if they would have the chance, while other entities are forced to comply with the provisions of these standards against their will. The research analyzed two types of economic consequences. First, market reaction (measured by share price) to news regarding the EU decision to mandatory adopt the IFRS was analyzed. Second, the authors considered the relative change of the cost of equity between the time when the EU started to consider IFRS adoption and the time when the decision to adopt IFRS was effectively final and binding on all member states. The results show that the stock-price reaction of UK firms to news favorable

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

(unfavorable) to mandatory IFRS adoption is positively (negatively) related to UK entities' willingness to adopt IFRS; moreover, the change in the cost of equity is negatively associated to the variables that express UK entities' willingness to adopt IFRS.

The general conclusion of this study is that mandatory IFRS adoption generates significant differences among entities, a very important issue when analyzing the cost and benefits of this process in a certain community. The authors conclude that „implementing mandatory IFRS has the potential to redistribute wealth among agents in society through changes to the cost of capital”.

The study of the research literature give us the opportunity to identify the main economic consequences of improved accounting quality following IFRS adoption and to differentiate a typology of these consequences; the economic consequences can be analyzed in the context of voluntary or mandatory IFRS adoption, according to the measure of achieving the objectives of the European and international accounting convergence, and according to the benefits perceived by each category of stakeholders that uses the information published in the financial reporting prepared in the spirit of IFRS standards.

Conclusions

Global accounting standards could represent one of the most important changes of accounting regulation. The decision of the European Commission to mandate IFRS adoption for all the entities listed on EU's regulated markets, the efforts made by different jurisdictions in order to achieve the convergence of national accounting regulations with IFRS, and the recent debates regarding the use of IFRS for US listed entities suggest that the international financial reporting standards represent a set of high-quality accounting standards. However, the economic consequences of this change are still debatable.

The research literature offers mixed evidence on the effects of IFRS adoption on the quality of accounting data. We consider that the effects of IFRS adoption on accounting quality must be interpreted in the context of country-specific factors, as well as entity-specific factors.

Testing the effects of IFRS adoption on accounting quality is an important endeavour, but not sufficient; such research should also investigate the economic consequences emerging from the publication of increased quality accounting data prepared and presented in accordance with IFRS.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

The study of the economic consequences of IFRS adoption must consider, on the one hand, the direct benefits for the entities that report this information and, on the other hand, the perceived benefits for different users of accounting data.

**Catering Approach to the Dividend
Payment Policy on the Warsaw Stock
Exchange***

JEL Classification: *G02; G10; G35*

Keywords: *catering theory of dividends; dividend policy; propensity to pay dividend; behavioural finance*

Abstract: Dividend payment policy is a significant issue of neoclassical theories of finance. One of the concepts which poses a challenge to the neoclassical approach to dividend payment policy is behavioural finance, including a catering theory of dividends. The aim of the article is to examine whether and to what extent the catering theory of dividends is reflected in the behaviour of shareholders and managers on the WSE. The opportunity to accomplish the aim of this paper was conditioned by the empirical verification of research hypothesis stipulating that the number of dividend payers increases if the dividend payers are priced by the capital market higher than the nonpayers. The empirical verification of hypothesis was conducted basing on the equal- and value-weighted dividend premium as well as dividend payment ratios. Moreover, descriptive statistics, Spearman's rank correlation coefficient, linear regression and coefficient of determination were used. The study was carried out on the basis of companies operating in the electromechanical industry sector that were listed on the WSE in the period between 1999-2013. The figures were taken from the Stock Exchange Yearbooks, Notoria

Serwis database and GPWInfostrefa platform. The preliminary results of empirical research in the range of the catering theory of dividends allow to draw a conclusion that this theory may be useful in explaining the dividend policy conducted by electromechanical industry companies listed on the WSE.

Introduction

The issues of net profit distribution are among the most significant strategic decisions made at the general meeting of shareholders. The division of net profit determines the conditions for the existence and development of the company and the growth of its competitiveness. Moreover, it is associated with the changes in the market value of the company. The dividend policy remains an issue that is not fully examined and explained by the theory, despite its significant impact on the capital market reaction and the future of company. The concept of dividend puzzle is being discussed not only by the neoclassical theory of finance, but more and more often it is explained by behavioural finance. Behavioural theories – including the catering theory of dividends – denying the assumption of capital market efficiency search for the new ways of explanation of capital market phenomena and complement the neoclassical theories by a new approach based on the irrational behaviour of managers or investors.

Assuming that the managers of stock companies behave in a rational way and investors categorize the companies in terms of dividend payment, we set the aim of the paper. This aim is to examine whether and to what extent the catering theory of dividends is reflected in the behaviour of the shareholders and managers on the Polish capital market. The opportunity to accomplish the objective of the paper was conditioned by the empirical verification of the research hypothesis stipulating that the number of dividend payers increases if the dividend payers are priced by the capital market higher than the nonpayers. Such a formulation of the research hypothesis results from the behavioural aspects of the stakeholders activities, in particular the managers and investors behaviour. When investors behave irrationally (i.e. they categorize companies taking into consideration only the criterion of dividend payment, not including company's investment opportunities), rational managers should recommend to the general meeting of shareholders a continuation of the dividend payments or an initiation of dividend in order to increase the market value of the company.

**The essence and place of catering theory among the dividend
payment theories – a literature review**

As part of the neoclassical theory of finance we should distinguish three main approaches to dividend policy. They are: neutral approach, pro-dividend approach and anti-dividend approach (Damodaran, 2007, p. 1013; Duraj, 2002, p. 124-137; Sierpińska, 1999, p. 131-151).

The representatives of neutral approach are Miller & Modigliani (1961, pp. 411-433) who proposed the dividend irrelevance theory. These authors, assuming a strong market efficiency as well as the lack of taxes and transaction costs, concluded that the dividend policy does not affect the market value of the company. Moreover, the investors are indifferent whether they receives income in the form of dividend or capital gains. According to the dividend irrelevance theory, the only factors that affects the market value of the company are the investment opportunity and company's ability to growth.

According to the pro-dividend approach an increase in the level of dividend is usually comprehended by investors as a positive signal sent by the company, indicating its good financial condition. An announcement of dividend payment leads to the increase in demand for shares and, consequently, to the growth in the market value of the company. According to Gordon (1959, pp. 99-105) dividend payment is also supported by the fact that along with the increase in the level of retained earnings cost of equity increases because investors require an additional premium for investment risk associated with the uncertainty of their future income. The uncertain future investment situation makes that the shareholders prefer dividend payment in regard to the possibility of achieving the potential capital gains in the indefinite future (Lintner, 1962, pp. 243-269).

The representatives of anti-dividend approach believe that the dividend payment has a negative impact on the market value of the company. The reasons for this are perceived in a different taxation of dividends and capital gains. If the dividend is taxed at the higher income tax rate than capital gains, the shareholders are not interested in dividend and prefer to retain the net profit (Litzenberger & Ramaswamy, 1979, pp. 163-195).

Among the neoclassical theories of dividend are also these considering the signalling theory and information asymmetry theory (see Asquith & Mullins, 1983, pp. 77-96; Pieloch-Babiarz, in print), agency theory (see Easterbrook, 1984, pp. 650-659; Jensen, 1986, pp. 323-329),

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

the organizational life cycle (see Mueller, 1972, pp. 199-219; Grullon et al., 2002, pp. 387-424) and clientele effect (Dhaliwal et al., 1999, pp. 179-194).

By contrast, Baker & Wurgler (2004a, pp. 1125-1165; 2004b, pp. 271-288) proposed a catering theory of dividends. This theory assumes that the behaviour of stock market investors is irrational. They categorize the companies taking into consideration only one factor – a dividend payment. When deciding, investors are focused solely on the fact of dividend payment. They do not pay attention to the amount of dividend payment as well as to the business development opportunities, the financial condition of the company, the size of its assets, the development stage of enterprise or the sector in which it operates. Therefore, investors divide the companies into two groups: dividend payers and nonpayers. In turn, the managers behave in a rational way. They analyse the market reactions adjusting the dividend payment policy to the changes in investor sentiment to dividend payers. The managers respond to the stock market investors' needs paying the dividend if the market value of dividend payers is high and omitting the dividend payments if the market value of nonpayers is high (see Konieczka & Szyszka, 2013, pp. 175-188). It should be added that the catering theory of dividends may be treated as an amplification of propensity to pay dividend concept formulated by Fama & French (see 2001, pp. 3-43).

The catering theory of dividends has been confirmed mainly in the US market. Baker & Wurgler (2004a, pp. 1125-1165) – introducing the concept of dividend premium, defined as a difference in the average market-to-book value ratios of dividend payers and nonpayers – proved that the number of dividend payers is strongly correlated with the level of dividend premium. The similar findings were derived from the studies conducted among stock companies in the UK (see Ferris et al., 2006, pp. 1149-1173). However, the catering theory of dividends has not been proven on the Japanese market (Tsuju 2010, pp. 1-14) as well as on the most developed capital markets of the European Union (Eije & Megginson, 2008, pp. 347-374). On the Polish capital market, preliminary research was conducted by Gajdka (2013, p. 141-156). The results of his study did not confirm the occurrence of catering on the Warsaw Stock Exchange.

The catering theory of dividends is still being improved and expanded with additional factors that may determine the behaviour of stock market investors and shape the market value of the company. Li & Lie (2006, pp. 293-308) extended the catering model of Baker & Wurgler with the amount of dividend payment. They found that the companies increase the level of payment if the dividend premium increases. If the dividend premium de-

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

creases, companies reduce dividend payments and replace them with the share repurchasing. The issue of dividend substitution was also discussed by Jiang et al. (2013, pp. 36-50) who introduced the concept of repurchase premium. Their research showed that if this premium is positive (i.e. the companies that conduct share repurchasing are valued by investors higher than the dividend payers) managers replace dividend payments by share repurchasing. Similar results of empirical research were also obtained by Kulchania (2013, pp. 180-195).

Li & Zhao (2008, pp. 673-694) extended the catering model with a variable describing the risk. They proved that when the capital market values the dividend payers, it considers the changes in stock market sentiment and investment risk. Their findings were confirmed by Hoberg & Prabhala (2009, pp. 79-116) who observed that after the model's extension by adding individual and systematic risk the dividend premium ceased to be relevant. On this basis, they formulated the conclusion that the dividend premium is a measure of risk.

Denis & Osobov (2008, pp. 62-82), in turn, proved that the propensity to pay dividend depends mainly on such factors as: the company's size, its development opportunities and its profitability. To less extent it depends on the level of dividend premium. Also, Julio & Ikenberry (2004, pp. 89-100) drew attention to the size and age of the company. They showed that the effect of catering theory of dividend disappears if the model is extended with these two additional variables.

Another variable that may complement the model is legislation. Ferris et al. (2009, pp. 1730-1738) proved that the catering theory of dividends applies mainly to those legal systems that take good care of minority shareholders. This situation occurs, for example, in the Nordic countries. De Rooij & Renneboog (2009, pp. 215-238) also focused on the legislation. These authors conducted research on the Dutch market. They proved that stock companies initiate dividend payments to compensate the minority investors for having few rights and decision possibilities.

Methodology of the research

The empirical research was conducted basing on 41 companies operating in the electromechanical industry sector that were listed on the Warsaw Stock Exchange in the period between 2000-2013. Due to the methodology of research, the calculations were also carried out for 1999. The figures were taken from the Stock Exchange Yearbooks, Notoria

Source: own study on the basis of Baker & Wurgler (2004, p. 1133).

Serwis SA database and GPWInfostrefa platform.

Empirical verification of the research hypothesis was conducted mainly on the basis of the methodology proposed by Baker & Wurgler (2004a, p. 1133). In the first stage of the study, we determined separately for each year the number of companies paying dividend (i.e. the companies initiating and continuing payments) as well as the number of companies not paying dividends (i.e. the companies omitting dividend payments and not paying dividend at all). Moreover, the structure of these companies was examined.

Then, the basic dividend payment ratios were calculated. We used three

ratios proposed by Baker & Wurgler (2004, p. 1133) and six author's ratios, including four total structure ratios (see Table 1). These additional ratios were added in the hope of a fuller study of the issue of shareholders' and managers' behaviour on the Warsaw trading floor.

In the next stage of the study, the dividend premium was calculated. It was defined as a difference in the average price-to-book value ratios (p/BV) of dividend payers and nonpayers. The dividend premium was calculated using two formulas, i.e. formula for equal- and value-weighted dividend premium (compare Kowerski, 2011, p. 91).

The formula for equal-weighted dividend premium in year t is as follows:

$$EWp_t^{D-ND} = \frac{1}{NP_t} \sum_{i=1}^{NP_t} (EW \frac{p}{BV})_{i,t} - \frac{1}{NN_t} \sum_{n=1}^{NN_t} (EW \frac{p}{BV})_{n,t}$$

where:

EWp_t^{D-ND} – equal-weighted dividend premium at the end of year t ,

$(EW \frac{p}{BV})_{i,t}$ – the value of price-to-book ratio at the end of year t for i payer,

$(EW \frac{p}{BV})_{n,t}$ – the value of price-to-book ratio at the end of year t for n non-payer,

NP_t – the number of payers in year t ,

NN_t – the number of nonpayers in year t .

The formula for the value-weighted dividend premium is as follows:

$$VWp_t^{D-ND} = \frac{1}{VP_t} \sum_{i=1}^{NP_t} [vp_{i,t} (VW \frac{p}{BV})_{i,t}] - \frac{1}{VN_t} \sum_{n=1}^{NN_t} [vn_{n,t} (VW \frac{p}{BV})_{n,t}]$$

where:

VWp_t^{D-ND} – value-weighted dividend premium at the end of year t ,

$(VW \frac{p}{BV})_{i,t}$ – the value of price-to-book ratio at the end of year t for i payer,

$(VW \frac{p}{BV})_{n,t}$ – the value of price-to-book ratio at the end of year t for n non-payer,

$vp_{i,t}$ – capitalization at the end of year t of i payer's shares,

$vn_{n,t}$ – capitalization at the end of year t of n nonpayer's shares,

VP_t – capitalization at the end of year t of all payers,

VN_t – capitalization at the end of year t of all nonpayers,

NP_t – the number of payers in year t ,

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

NN_t – the number of nonpayers in year t .

Next, we determined the median for the dividend premium (calculated according to both formulas) and divided the research period into the years of relatively high and relatively low dividend premium. The years of relatively high dividend premium are these years for which the dividend premium was higher than the median. Otherwise, it was the year of relatively low dividend premium. Assuming that the dividend payment decisions are based on the historical data it was supposed that the level of dividend premium in one year affects the dividend payment decision in the following year.

In the next stage, the average values of dividend payment ratios for years of relatively high and relatively low dividend premium were compared. Moreover, medians and standard deviations were calculated. Then, we determined Spearman's rank correlation coefficient between the equal- and value-weighted dividend premium and dividend payment ratios. These actions were undertaken in order to examine the occurrence of dependence between the relative market value of dividend payers and propensity to pay dividend.

In the last part of the study, four models of linear regression were used. These models describe the relationship between the dividend premium in year $t-1$ (calculated in two ways) and the value of *Init*, *Cont*, *List* and *Omit* ratios in year t (see Table 2).

Table 2. Linear regression models for the catering theory of dividends

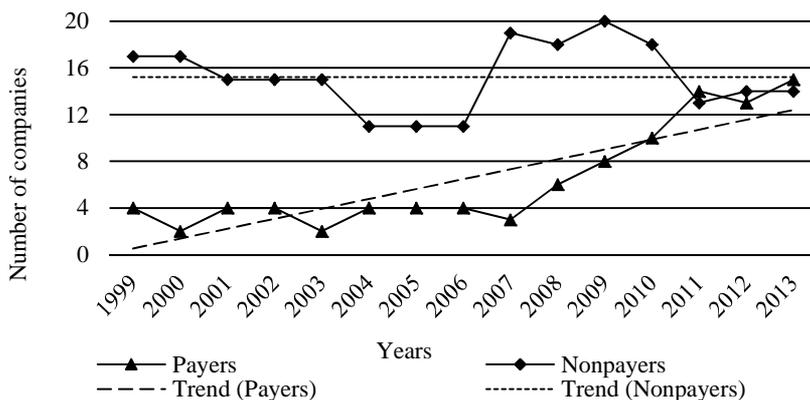

Dependent variable	Dividend premium	
	Equal-weighted	Value-weighted
Dividend payment initiation ratio	$Init_t = \alpha + \beta EWp_{t-1}^{D-ND} + \varepsilon_t$	$Init_t = \alpha + \beta VWp_{t-1}^{D-ND} + \varepsilon_t$
Dividend payment continuation ratio	$Cont_t = \alpha + \beta EWp_{t-1}^{D-ND} + \varepsilon_t$	$Cont_t = \alpha + \beta VWp_{t-1}^{D-ND} + \varepsilon_t$
Dividend payment ratio of newly listed companies	$List_t = \alpha + \beta EWp_{t-1}^{D-ND} + \varepsilon_t$	$List_t = \alpha + \beta VWp_{t-1}^{D-ND} + \varepsilon_t$
Dividend payment omission ratio	$Omit_t = \alpha + \beta EWp_{t-1}^{D-ND} + \varepsilon_t$	$Omit_t = \alpha + \beta VWp_{t-1}^{D-ND} + \varepsilon_t$

Characteristics of the companies operating in the electromechanical industry sector in the period between 1999-2013

In the majority of years of research period, among companies operating in the electromechanical industry sector dominated dividend nonpayers. Most of companies did not decide to conduct a dividends payment during the economic downturn, i.e. between 2007-2010. The successive increase in the number of dividend payers have been observed since 2007. In the last three years of the research period, the number of dividend payers and nonpayers was at a similar level. The only years in which relatively more companies conducted the dividend payment were 2011 and 2013 (14 and 15 companies, respectively). In the period between 1999-2013, a horizontal trend line was observed for nonpayers, while for the dividend payers linear trend was increasing (see Figure 1).

Figure 1. The number of dividend payers and nonpayers in electromechanical industry sector in the period between 1999-2013

Source: own study on the basis of Roczniki Gieldowe (2001-2014), Notoria Serwis SA and GPWInfostrefa.

Among the dividend payers dominated those companies that were continuing dividend payments. This may denote the stability of dividend policy in the analysed sector. In 2003 and 2007, all companies that paid the dividend did the same in the previous year. It should be added that these were only 2 and 3 companies, respectively. The largest number of companies continued dividend payments in the last four years of research period. In

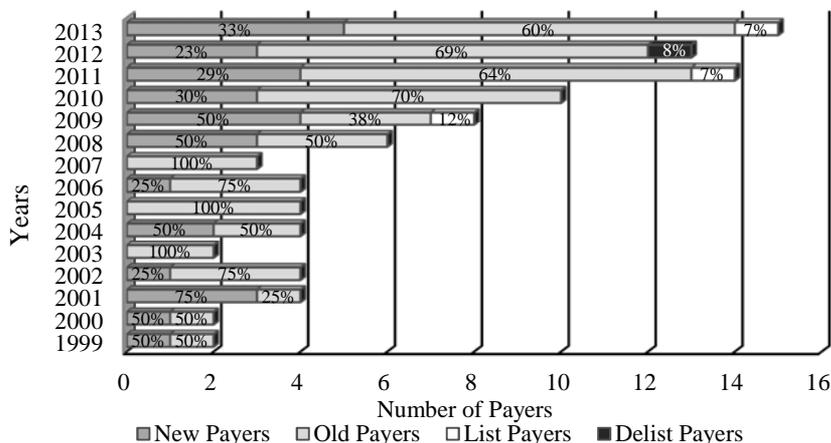

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

2010, the share of companies continuing the dividend payments in a total number of dividend payers amounted to 70% (7 companies), in 2011 stood at 64% (9 units), in 2012 was equal to 69% (9 enterprises) and in 2013 reached the level of 60% (9 companies). In 2001 and 2009, the share of companies continuing the dividend payment in a total number of analysed companies was the lowest. In 2001 it amounted to 25% and in 2009 it stood at 38% (1 and 3 companies, respectively).

The second largest group of dividend payers comprised of the companies that did not pay dividend in the previous year. Their largest share in total payers was observed in 2001 and amounted to 75%. In 2004, 2008 and 2009, this share stood at 50%. The majority of companies, that in the previous year did not pay dividend, decided to pay it in the last year of analysis, i.e. in 2013. It was 5 companies (33% of the study group).

In the entire research period, only three companies that in a given year were newly listed on the main market of the Warsaw Stock Exchange (including those companies passing from NewConnect market), paid a dividend in the same year. In 2009 it was Centrum Klimat SA, in 2011 it was Zamet Industry SA and in 2013 it was Newag SA. Only one company paid dividend and then, in the same year, was excluded from stock exchange trading. This occurred in 2012 (see Figure 2) and the company was Centrum Klimat SA.

Figure 2. The number and structure of dividend payers in electromechanical industry sector in the period between 1999-2013

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

Among dividend nonpayers dominated those companies that did not distribute cash to shareholders in the previous year. Most of such companies were observed in 2001 (93% of the study population), in 2011 (86%), in 2008 (83%) and in 2010 (83%). In 2008 and 2010, the majority of companies continued strategy of so called zero dividend payment policy (15 companies per year). Most companies omitted dividend payment in 2012 (4 cases) as well as in 1999, 2000 and 2009 (3 companies per year). However, in the 2004, 2005 and 2013 none of the companies paying dividend in the previous year decide to discontinue the payment. The largest number of newly listed companies that did not pay dividend was observed in 2007 (7 cases, accounting for 32% of nonpayers in this year). In 2008 and 2009, there were 3 such cases per year. In 2005 and 2013, we observed 2 such cases per year. Moreover, there were just a few companies that did not pay dividend and were delisted in the same year. In 2002, 2004 and 2010, there were two such cases per year, and in 2003, 2005, 2007 and 2013, we observed only one such case per year (see Figure 3).

Figure 3. The number and structure of dividend nonpayers in electromechanical industry sector in the period between 1999-2013

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

The highest percentage of companies initiating the dividend payment was observed in the last years of research period. Dividend payment initiation ratio reached the highest value in 2013, when 38,46% of the previous nonpayers initiated dividend payments. In 2012, the value of $Init_t$ stood at 23,08%, while in 2009 and 2011 this ratio amounted to 22,22% per year. The lowest value of this ratio was equal to 0%. None of the previous nonpayers decided to initiate dividend in three last years of research period, i.e. in 2003, 2005 and 2007. The average annual dividend payment initiation ratio reached the level of 13,87%, its standard deviation stood at 10,55% and median amounted to 15,59% (see Table 3).

All companies paying the dividend in year $t-1$ decided to continue the payments in 2004-2005 and in 2008. The high value of dividend payment continuation ratio was observed in 2011 (this ratio amounted to 90%) and in 2010 (this ratio reached the level of 87,5%). In the last two years of the study the value of $Cont_t$ amounted to 69,23% per year. In the period between 2000-2013 the average annual dividend payment continuation ratio stood at 72,57%, median reached the level of 75% and standard deviation amounted to 21,74% (see Table 3).

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

In the case of companies that were listed on the Warsaw trading floor for the first time, most of them paid dividend in 2011 (50% of newly listed companies). The high value of $List_t$ was also observed in the last year of research period. In 2013, this ratio stood at 33,33%. Moreover, in most years of the analysed period the value of $List_t$ was equal to 0% or – due to the lack of newly listed companies in electromechanical industry sector – impossible to calculate.

The highest value of dividend payment omission ratio was observed in 2000 when 75% of dividend payers refrained from dividend payments. In 2001, 2003 and 2009, the value of $Omit_t$ stood at 50% and in 2012-2013 it was equal to 33,77% per year. The average annual value of dividend payment omission ratio amounted to 27,43%, median stood at 25%, and standard deviation reached the level of 21,74%.

The analysis of share of the companies initiating dividend payments in the total number of payers showed that the value of $Init Share_t$ was the highest in 2001. It was equal to 75%. The high value of this ratio was also observed in 2009, when 62,5% of dividend payers accounted for the companies initiating the dividend payments. In 2000, 2004 and 2008, the value of $Init Share_t$ stood at 50% per year. The average value of this ratio was equal to 33,31%, median reached the level of 32,86% and standard deviation was 22,45%.

Analysing the share of dividend payers (including the companies initiating and continuing payments) in the total number of companies operating in electromechanical industry sector, it should be noted that relatively many companies paid dividend in the period between 2009-2013. The highest value of $Pay Total_t$ was observed in 2011 and 2013 (51,85% and 51,72%, respectively). In the research period, the dividend payers accounted for 28,5% of the companies operating in the examined sector. Moreover, in half of the years at least 26,67% of companies paid dividend.

The companies that initiated dividend payments accounted for 9,84% of the study population, and the companies that continued dividend payments accounted for 18,4% of the total number of companies. Median was at the level of 10,91% and 14,41%, respectively, and standard deviation stood at 6,85% and 9,48%, respectively.

The highest value of $Omit Total_t$ was observed in 2012. It was equal to 18,52%. In contrast, the lowest value of this ratio occurred in 2004, 2005 and 2008. It stood at 0%, which means that in those years no company resigned from dividend payment. The average annual value of this ratio stood

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

at 6,37%, median reached the level of 4,9% and standard deviation was equal to 5,58%.

**The results of empirical studies on the occurrence of catering approach
to dividend payments on the Warsaw Stock Exchange**

The highest average price-to-book value ratio, calculated for dividend payers in the period between 2000-2013, was observed in 2007. In this year, the average value of EWp/BV was equal to 3,76 and the average value of VWp/BV stood at 4,43. The lowest average values of this ratio, in turn, were observed in 2001 (0,51 and 0,58, respectively). The average annual value of EWp/BV for dividend payers stood at 1,69 and VWp/BV was equal to 2,38. The median amounted to 1,67 and 2,33, respectively, and standard deviation was equal to 0,94 and 1,15, respectively.

In the case of nonpayers, the highest average value of price-to-book value ratio was observed in 2013. In this year, EWp/BV amounted to 3,69. In turn, VWp/BV was the highest in 2006. It was equal to 3,79. The average annual values were equal to 1,38 and 1,40, respectively. Median stood at 1,12 and 1,18, respectively (see table 4).

The dividend premium was positive in the majority of analysed years. That means that the capital market was usually pricing dividend payers higher than nonpayers. The highest dividend premium was observed in 2007 (EWp^{D-ND} stood at 1,68, and VWp^{D-ND} was equal to 2,19). The lowest equal-weighted dividend premium occurred in 2013. It was equal to -1,69. The lowest value-weighted dividend premium, in turn, was observed in 2001. It stood at 0,14. The average annual value of EWp^{D-ND} amounted to 0,31, and VWp^{D-ND} was equal to 0,99. Median of equal-weighted dividend premium stood at 0,40, and median of value-weighted dividend premium reached the level of 0,67.

By adopting the value of median as a reference level of the dividend premium, which is used by the companies in the process of deciding to pay (i.e. to initiate or to continue dividend payments) or not to pay dividend (including dividend omissions), the research period was divided into years of relatively high and relatively low valuation of dividend payers. For the year of relatively high valuation of dividend payers was considered that year, when the dividend premium was at least equal to the median. Otherwise, that year was considered to be the year of relatively low valuations of dividend payers. The values of equal-weighted dividend premium as well as its median are shown in Figure 4.

Figure 4. The values of equal-weighted dividend premium and its median in the period between 1999-2013

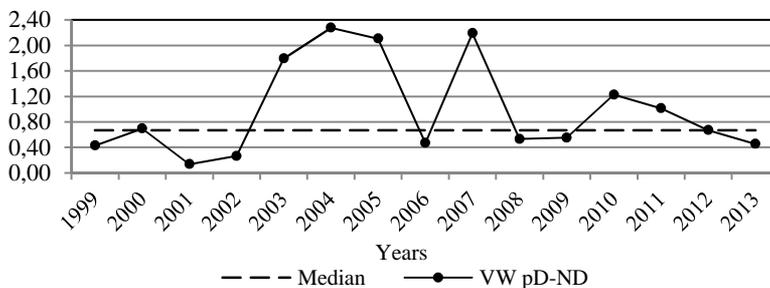

Source: own study on the basis of Roczniki Gieldowe (2000-2014) and GPWInfostrefa.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

Consistent with the catering approach, the decision to pay dividend is made by the company on the basis of the level of dividend premium for a previous year. For the years of relatively high equal-weighted dividend premium were considered the following years: 2003, 2004, 2005, 2007, 2009, 2010, 2011 and 2012. This means that the companies should be more likely to pay dividend in years: 2004-2006, 2008 and 2010-2013 (see Figure 4). The years of a relatively high value-weighted dividend premium are as follows: 2000, 2003, 2004, 2005, 2007, 2010, 2011 and 2012. This means that the companies should be more likely to pay dividend in the following years: 2001, 2004-2006, 2008 and 2011-2013 (see Figure 5).

Figure 5. The values of value-weighted dividend premium and its median in the period between 1999-2013

Source: own study on the basis of Roczniki Gieldowe (2000-2014) and GPWInfostrefa.

The values of descriptive statistics of dividend payment ratios seem to confirm the catering activities of managers of stock companies operating in electromechanical industry sector. In the years of relatively high dividend premium (calculated in two ways) the average values of $Init_t$, $Cont_t$ and $List_t$ are higher than in the years of relatively low dividend premium. In the years of relatively high valuation of dividend payers, measured with the equal-weighted dividend premium, the average dividend payment initiation ratio was equal to 17,95%. In the years of relatively low dividend premium, in turn, $Init_t$ stood at 8,91% (see Table 5).

Source: own study on the basis of Roczniki Gieldowe (2000-2014) and GPWInfostrefa.

In the years of the relatively high dividend premium, 86,37% of dividend payers decided to continue dividend payments, while in the other years *Cont_t* was lower and amounted to 54,17%. A similar relationship can be observed among the companies that were listed on the Warsaw Stock Exchange for the first time. On average, 16,67% of these companies initiated dividend payments in the years of relatively high dividend premium. If the dividend premium was low or it was negative dividend was paid only by 8,33% of newly listed companies.

The similar conclusions on the dividend catering may be drawn by analysing the values of *Pay Total_t*, *Init Total_t*, *Cont Total_t*, and *Omit Total_t*. The catering behaviour of companies was also confirmed by examination of the median values of these ratios in the years of relatively high and relatively low dividend premium. Moreover, the compatible findings may be formulated when using the value-weighted dividend premium (see Table 5).

The preliminary conclusions on the catering behaviour of companies should be verified by studying the dependence between dividend payment ratios and dividend premium. The values of Spearman's rank correlation coefficient indicate the existence of relationship between the market valua-

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

tion of companies and the number of dividend payers. The strongest unidirectional dependence was observed between the dividend premium and the number of companies continuing dividend payments. The value of Spearman's rank correlation coefficient was equal to 0,78 if calculation was based on EWp_{t-1}^{D-ND} and it stood at 0,63 if VWp_{t-1}^{D-ND} was used. A strong unidirectional dependence was also observed between the dividend premium and value of $List_t$. It was equal to 0,6 and 0,86, respectively. The weakest unidirectional dependence took place in the case of $Init_t$ (0,04 and 0,20, respectively). In contrast, the strongest bidirectional dependence was observed between the dividend premium and dividend payment omission ratio ($Omit_t$). It was equal to -0,86 and -0,68, respectively (see Table 6).

Table 6. The values of Spearman's rank correlation coefficients for the dependence between dividend premium and dividend payment ratios

Dividend premium	$Init_t$	$Cont_t$	$List_t$	$Omit_t$	$Init$ $Share_t$	Pay $Total_t$	$Init$ $Total_t$	$Cont$ $Total_t$	$Omit$ $Total_t$
EWp_{t-1}^{D-ND}	0,04	0,78	0,60	-0,86	-0,12	0,46	0,13	0,46	-0,52
VWp_{t-1}^{D-ND}	0,20	0,63	0,86	-0,68	0,09	0,45	0,27	0,36	-0,64

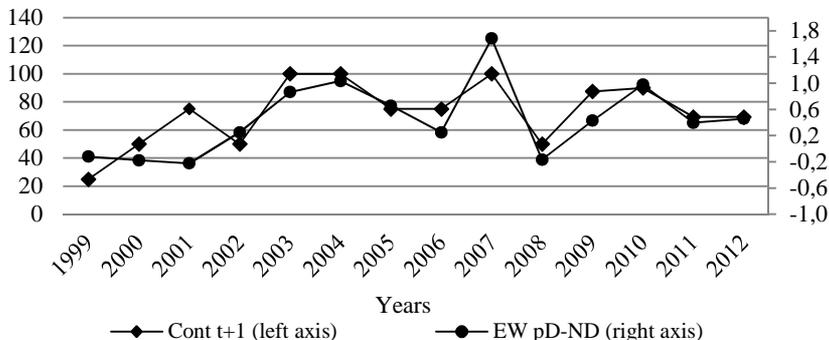

Source: own study on the basis of Roczniki Gieldowe (2000-2014) and GPWInfostrefa.

The unidirectional dependence between the dividend premium and the number of dividend payers is particularly seen in the case of companies continuing dividend payments. If the dividend payers were priced higher than nonpayers in year t , relatively more companies continued dividend payments in year $t+1$. If the dividend premium was low or negative in year t , some of the companies omitted the dividend payment in the following year (see Figure 6).

On the existence of a relationship between the relative market value of dividend payers and the number of companies conducting the dividend payments indicates some of estimated values of the parameter β in the linear regression models (positive when the dependent variable is $Init_t$, $Cont_t$ and $List_t$, and negative in the case of variable $Omit_t$). If the dependent variable is the share of companies continuing dividend payment in the year t in the number of dividend payers in year $t-1$, the value of the parameter β is positive and statistically significant at the significance level of 0,01. Thus, the increase in the value of the dividend premium (calculated in two ways) is accompanied by a relative increase in the number of companies continuing dividend payments. Moreover, a variability of $Cont_t$ is explained in the model by variability of equal-weighted dividend premium in 59% and by variability of value-weighted dividend premium in 57%.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

Figure 6. The dividend premium EWp_{t-1}^{D-ND} and the value of $Cont_t$ (one-year-ahead)

Source: own study on the basis of Roczniki Gieldowe (2000-2014) and GPWInfostrefa.

The occurrence of the catering behaviour of company is also visible in the case of $Omit_t$, for which the value of parameter β is negative and statistically significant at the significance level of 0,01. In this case, the coefficient of determination amounted to 51% and 45%.

Table 7. Estimation of linear regression models for the dependence between the dividend payment ratios and dividend premium

Dependent variable	Parameter β (<i>t</i> -Student)		Intercept α (<i>t</i> -Student)		Coefficient of determination R^2	
	<i>EW</i>	<i>VW</i>	<i>EW</i>	<i>VW</i>	<i>EW</i>	<i>VW</i>
$Init_t$	0,28 (1,07)	0,21** (0,78)	0,95 (2,63)	0,89*** (1,96)	0,09	0,05
$Cont_t$	1,12* (4,17)	1,09* (3,97)	2,23* (6,02)	1,68* (3,57)	0,59	0,57
$List_t$	0,27 (1,22)	0,14 (0,61)	0,10 (0,34)	0,12 (0,31)	0,11	0,03

Symbols: * statistically significant at the significance level of 0,01,
** statistically significant at the significance level of 0,05,
*** statistically significant at the significance level of 0,10.

Source: own study on the basis of Roczniki Gieldowe (2000-2014) and GPWInfostrefa.

If the dependent variable was $Init_t$ or $List_t$, the positive values of the parameter β were observed. This may indicate the use of catering by managers of companies operating in electromechanical industry sector.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

It should be noted that statistically significant the value of the parameter β was obtained at a significance level of 0,05 in the case of linear regression model in which the explanatory variable was VWp_{t-1}^{D-ND} and the dependent variable was $Init_t$. However, the value of the R^2 was very low and amounted to 5% (see Table 7).

Conclusions

The dividend payers operating in electromechanical industry sector in the period between 1999-2013 were valued by the investors of the Warsaw trading floor higher than nonpayers. The decisions on dividend payment (both continuing and initiating dividend payments) were made more frequently in the years of relatively high dividend premium. If the dividend premium was relatively low or negative, some of the companies decided not to pay dividend. Such behaviour of stock companies may confirm that the managers take action in accordance with the catering theory of dividends. They cater to investors by paying dividends if the capital market put a stock price premium on payers. They do not pay dividends if investors prefer nonpayers.

The results of the study presented in this paper are of the preliminary nature, so conclusions should not be generalized. The conducted empirical research are *in statu nascendi*, so it is necessary to consider the need for its intensification and extension as well as application of the other dividend payments ratios and different methods of dividend premium calculation. There is no doubt that research must be extended with the macroeconomic factors (e.g. the economic situation), the development and technological opportunities of sector as well as the investment strategies of companies.

**What Determines the Reforms
of Employment Protection Legislation?
A Global Perspective**

JEL Classification: *D02; D78; J08; J32*

Keywords: *political economics; employment protection legislation; labor law; labor market institutions; labor market policy*

Abstract: The aim of this research was to identify determinants of the employment protection legislation reforms in the global perspective. The study was based on the Labor Freedom index published by the Heritage Foundation, which allowed to include 179 countries in the research that were observed in the period 2003-2013. The conducted research has indicated that changes in GDP and the level of employment in industry may induce the introduction of labor reforms. The changes in the labor law also occurred to be correlated with the number of the nearly excluded from the labor market (the long-term unemployed and youth not in education, employment or training) and also with changes in the government expenditure. However, all these factors may lead to substantially various reform programs in particular countries due to the heterogeneous political pressure of the labor market interest groups and different governmental determination in introduction of the reforms.

Introduction

The labor economics literature has generated a lively and continuously growing discussion concerning the role of labor market regulations for the labor market performance for the last three decades (Blanchard, 2006, pp. 13-35). Nowadays, there are no doubts that the situation on the labor market is dependent on its institutional framework (Lehmann & Muravyev, 2012). In this context it is quite surprising that only a relatively small number of studies was aimed at answering the question of what determines the labor institutional framework in the particular countries.

The existing analyses in this area have been focused mainly on the OECD economies and were aimed primarily at explaining the differences among levels of various institutional indicators in the particular countries. In consequence, there is a need to develop this strand of research by conducting more analyses on determinants of the changes of the labor market institutions and by expanding the geographical scope of these studies. Therefore, the aim of this research is to identify determinants of the employment protection legislation reforms around the world. The analysis is focused only on the employment protection due to data availability. The group of the analyzed countries comprises of 179 entities, while the time scope is 2003-2013.

In the next section the methodology of the research is briefly described. Thereafter, an analysis of the determinants of labor market reforms based on the literature is presented. In the next section the general tendencies of the employment protection legislation changes in the research period are identified and analyzed. Thereafter, the results of the econometric investigation are presented. The last section concludes the article.

Methodology of the research

Identification of the determinants of employment protection legislation reforms presented in this article was divided into two main steps. In the first step the critical analysis of the literature was conducted in order to select potential determinants of these reforms. In the next step the econometric investigation was executed in order to find which potential determinants are statistically significant. During this investigation the panel data models were used.

It was decided to use the index of Labor Freedom that is published by the Heritage Foundation (2014) as a quantitative measure of the employ-

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

ment protection legislation. It is an index that reflects various aspects of the legal and regulatory framework of a country's labor market, including regulations concerning minimum wages, laws inhibiting layoffs, severance requirements, and measurable regulatory restraints on hiring and hours worked. It takes values from 0 to 100 – the higher the value is, the lesser is the guaranteed employment protection. Although the index tries to capture various labor market institutions, description of its methodology suggests that it predominantly measures the strictness of the employment protection legislation (Heritage Foundation, 2014). It can also be noticed that it is similar to the EPL index published by the OECD (2014). Although the EPL is widely used in the literature, its values are regularly collected only for the OECD countries, whereas the Labor Freedom index has been assembled for 184 countries in 2014. It has been published from 2005 and refers to the period from 2004 to 2014. Therefore, the Labor Freedom index allows not only to analyze the short-term changes in the labor legislation, but also to identify the medium-term tendencies, because all the published values were estimated with the use of the same methodology.

All indicators that were analyzed as potential determinants of the employment legislation were derived from the World Development Indicators database (World Bank, 2014). It was decided to use this data set, because the measures for almost all countries investigated by the Heritage Foundation are published there (Taiwan is the only exception).

Not surprisingly, for such a broad set of countries the missing values occurred to be a significant obstacle during the study. Therefore, countries or years with almost no observations had to be removed. The obtained unbalanced panel data set comprised of 179 countries that were observed in the period 2003-2013.

Insights from the literature

The institutions of the labor market may be defined as rules influencing the scope of choices available to the participants of this market with respect to the amount of work offered or demanded, and the level of wages (Boeri & Van Ours, 2008, p. 3). Although these rules can be both formal and informal, most analyses focus only on the formal rules due to data availability (and so it was done in the presented study).

The number of studies concerning the labor market institutions began to rise rapidly in the 80's of the 20th century (Blanchard, 2006, pp. 13-35). It was a time when many labor economists tried to explain the mechanism of

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

the unemployment hysteresis occurrence. Labor market institutions were found not only to influence the hysteresis in a significant degree, but also allowed to explain why the strength of this effect is different in the particular countries. Layard, Nickell and Jackman (2005, p. xxvii) state that labor market institutions indicators can explain around 55% of the unemployment volatility in highly developed states in years 1960-1990.

However, while there are no doubts now that the labor market institutions matter, it is quite surprising that relatively few researchers have given significant consideration to the question stated by Arpaia and Mourre (2005, p. 17-18): ‘why labor market institutions are as they are, and to what extent the current configuration of labor market institutions might be desirable despite sometimes their unfavorable impact on labor market performance’.

One possible answer to this question is that labor market institutions have their origins in the history of the country law or its culture (Arpaia and Mourre 2005, p. 18; Algan & Cahuc, 2009). The second proposed explanation (Boeri & Van Ours, 2008, p. 19) indicates that a competitive market for labor does not exist in practice. Informational asymmetries, externalities, search frictions and structural mismatches are the reasons why the labor market performance is usually far from the fully competitive market equilibrium. Thus, imposing institutions on the labor market may allow to attain at least the second-best outcome. The third view indicates that labor market institutions are introduced, because they remain beneficial for the society, even if they hamper the labor market performance. For instance, Bertola and Koeniger (2004) show that strict employment protection and high unemployment benefits may be introduced in order to reduce labor income fluctuations in countries with under-developed financial systems, where consumer credit is relatively scarce. This argument can be especially significant for developing countries. Boeri and Van Ours (2008, p. 19) argue also that labor market institutions can increase the income equality effectively, which can also be perceived as socially beneficial. Finally, many labor market institutions exist, because they are beneficial for some interest groups, especially for the employees who are the largest group of voters on the labor market (Saint-Paul, 1996, 2002; Boeri, Conde-Ruiz & Galasso, 2003). Employees tend to exert pressure on the government to provide them protection against labor market risks at the cost of other labor market groups and labor productivity. This mechanism is present in every

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

country, however its strength can be very different¹. It should be stressed that all these factors do not exclude one another, but operate complementarily, which leads to the substantial variety of institutional frameworks in the particular countries.

Therefore, it can be concluded that labor market institutions are reformed if one of the previously mentioned factors has changed. The work of Blanchard and Wolfers (2000) suggests that these changes can especially be a consequence of adverse macroeconomic shocks. Such a shock strongly affects the situation on the labor market, which induces the government to show its competence and react in some way (Saint-Paul, 1996, p. 276). Thus, the scope of reforms will be dependent on preferences and determination of the government. For instance, it can offer more protection to employees. On the other hand, however, an adverse shock can decrease the political opposition of the insiders against labor reforms (Saint-Paul, 1996, p. 280), because they become more exposed to the risk of being dismissed, and in consequence, grow more interest in instruments that help the unemployed to find a job. In such a situation the government can increase the ALMP expenditure without changing the labor law (or even decide to introduce some liberalization of the law, for instance for temporary contracts). Therefore, it is not clear what will be the direction of labor reforms in reaction to such a shock, because it will depend on the political strength of particular groups on the labor market, on their preferences, on the scale and nature of the shock, and on the government decisions.

These shocks do not need to be demand shocks only. Changes in the level of competition on the goods market (caused for example by the technological progress or by opening to new international markets) may also lead to changes in the labor market institutions (Boeri, 2005). When the level of competition rises, existing labor regulations cause higher forgone efficiency, and in consequence, the difference between achieved social welfare and potential social welfare is higher. In such a situation it would be economically desirable to liberalize the labor regulations, which – however – could be politically unattainable due to the opposition of some

¹ For instance, in order to ensure higher labor market flexibility many governments decided to liberalize regulations concerning the temporary employment. In the case of Germany (Eichhorst & Marx, 2011), although the insiders had objected to such flexibilization in principle – once the reforms were in place – they reacted with decreasing their pressure on ensuring greater employment protection in order to strengthen their competitiveness relative to flexible workers. On the other hand, relaxing regulations of the temporary contracts in Spain (Dolado, García-Serrano, & Jimeno, 2002) increased the pressure from permanent employees to secure their posts, which resulted in formulation of the dual market.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

groups of employees (Boeri & Van Ours, 2008, p. 21). Thus, the government may only decide to propose a two-tier reform (Boeri & Garibaldi, 2006) which will relax the labor regulations only for some groups (for instance temporary employees).

Paradoxically, this opposition may be so strong that it will induce the government to deliberately introduce some labor protective institutions at the cost of social welfare. The government can for example offer some form of compensation to the insiders in order to gain their support for the reform (Drazen, 2002, pp. 624-625). For instance, it may create a special ALMP program or increase the level of unemployment benefits. The government may also decide to implement reforms gradually if various interest groups are against some parts of the reform only (Drazen, 2002, pp. 626-632). This 'divide and conquer' strategy will extend the time span between a macroeconomic shock and labor market changes, and in fact disturb a relationship between these two phenomena.

Although the conducted review of the literature was succinct, it allows to conclude that labor market institutions reforms can be triggered by a broad set of factors among which presumably the most important are adverse demand shocks that significantly affect the situation on the labor market and positive supply shocks that allow to increase the labor productivity. However, due to the political opposition of the insiders, these changes can have various scope, time of implementation and even different direction².

Therefore, it can be concluded that although the literature suggests many potential determinants of labor reforms, it does not give clear-cut conclusions concerning their significance and strength of their influence. Thus, there is a need to identify these determinants empirically and to assess their average impact, which will be the goal of the following sections.

Global tendencies in the employment protection reforms

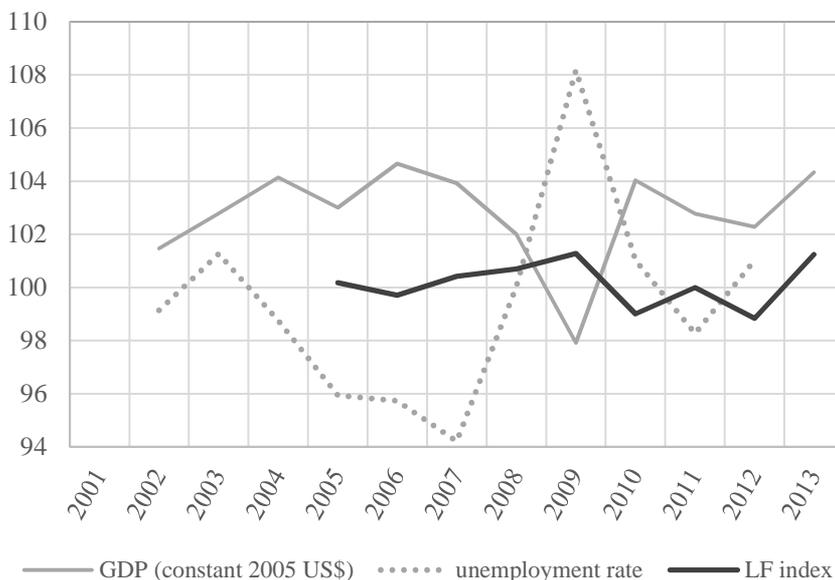

The year to year changes in global GDP, unemployment rate and Labor Freedom index are presented on Figure 1. The data indicates that employment protection legislation in the world was (on average) being liberalized slightly in years 2006-2009, so in the time when many economies were

² Thus, it is not surprising that labor regulations are changed relatively often. Boeri and Van Ours (2008, p. 23) state that in the EU countries in years 1986-2005, on average, more than 1.2 labor reforms were conducted per year and country, however more than 90% of the reforms can be perceived as marginal.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

experiencing growth. That process was stopped in 2009 when the global unemployment rate reached its peak and the world economy fell into recession. The collected data indicates that between 2010 and 2012 the mean world value of the Labor Freedom index was decreasing. Therefore, it can be concluded that the governments decided rather to support the insiders and strengthen the employment protection in reaction to the adverse shock. It probably resulted in more difficulties in decreasing the unemployment rate during the following recovery.

Figure 1. Year to year changes in GDP, unemployment rate and Labor Freedom index (global averages, last year = 100).

Note: the values of the Labor Freedom index are given for the concerned year, not for the year of their publication.

Source: own elaboration based on the Heritage Foundation (2014) and World Bank (2014).

The year to year changes in the Labor Freedom index can be treated as an indicator of the short-term employment protection reforms. Additionally, we calculate also an index of the long-term reforms which is aimed at representing the main tendency of labor reforms in each of the analyzed states with the use of a single variable. It is calculated as a relative differ-

ence between the largest and the smallest values of the Labor Freedom index for each particular country.

More precisely, for each country we first identified years when the minimum and the maximum value of the Labor Freedom index were observed (they were denoted as t_{min} and t_{max} respectively). Secondly, the long-term reform (LTR) index was calculated as³:

$$LTR = \begin{cases} \max(LF_t) / \min(LF_t) \cdot 100\%, & \text{if } t_{max} > t_{min} \\ \min(LF_t) / \max(LF_t) \cdot 100\%, & \text{if } t_{max} \leq t_{min} \end{cases}, \quad (1)$$

where t means time and LF represents Labor Freedom index. The absolute difference of t_{min} and t_{max} indicates the duration of the long-term reform. Therefore, whenever the long-term reform index takes a value below 100%, it means that the analyzed country has strengthened the labor protection (and in consequence the Labor Freedom index has fallen), whereas a value above 100% means that the labor law regulations have been liberalized. If the index had a value equal to 100%, it would mean that the analyzed country did not change labor regulations at all in the analyzed period (then the maximum value would be equal to minimum).

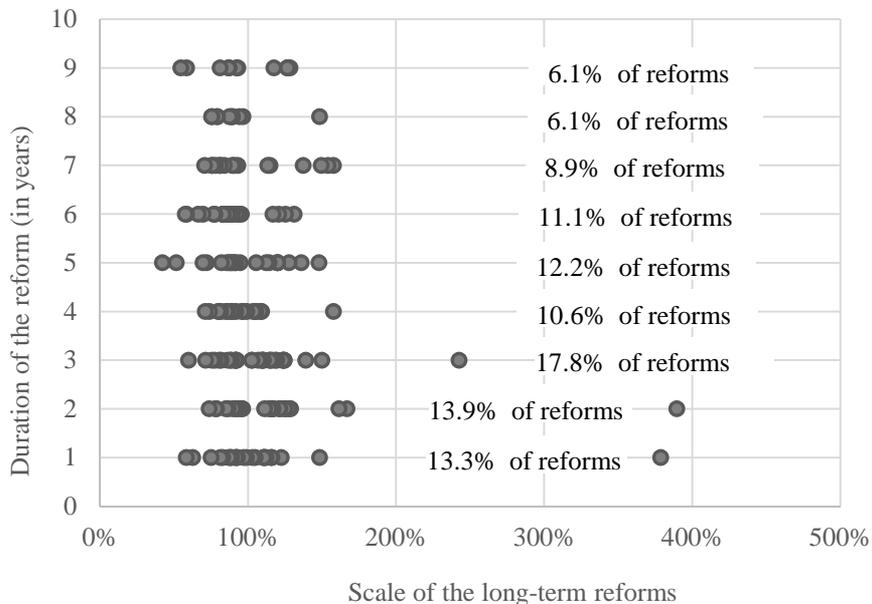

The values of the long-term reform index are presented on Figure 2. As it can be noticed, the durability of labor law reforms is significantly diversified, however, generally shorter duration is more probable than longer one. The modal duration is 3 years, which may indicate that more governments prefer to apply the gradual rather than the immediate approach to employment protection reforms. Although the average value of the long-term index was equal to 102,8%, the results reveal that in 58.3% of countries the labor freedom was limited (in the case of 18.3% states by more than 20%), while only in 41.7% the employment regulations were liberalized (in the case of 18.9% states by more than 20%). One may conjecture that the estimation of

³ It should be added that the lowest value of the Labor Freedom index in the data set was equal to 20, therefore there was no risk of dividing by zero. Of course, one can imagine many other indicators than can represent the long-term reforms. It was decided to use this one, because it assigns single value for each country and ensures that every country is equally represented in the data set. Moreover, this index allows to capture the most radical reform for each country, both gradual and immediate.

the average value was biased by 3 outliers (for Bahrain, Burma and Libya respectively) that are clearly visible on Figure 2. However, even after their exclusion the average values of the long-term reform indices higher than 100% was proportionally greater than analogous average for the values of the index lower than 100% (122% to 83% respectively). This indicates that the average long-term labor law liberalization was greater than the average long-term labor freedom limitation by 5 percentage points⁴.

These result can be seen in the perspective of political opposition from employees against labor law liberalization. The calculated indicators suggest that governments often decide to postpone the reforms that relax the employment protection. However, when the reforms are conducted, they are deeper than the typical changes that increase the level of that protection.

Figure 2. The scale and durability of the long-term reforms in the analyzed countries.

Source: own calculations based on the Heritage Foundation (2014).

⁴ It was calculated as: $(122 - 100) - (100 - 83) = 5$

Econometric analysis

The empirical analysis was focused on identifying determinants of the short-term labor law reforms that were measured by the year to year changes in the Labor Freedom index. Although a separate analysis was also conducted for the long-term reforms, it was decided not to present it, because it did not allow to identify any significant determinants of the labor market reforms, which was probably a consequence of a relatively small number of observations (one value for each country).

The empirical analysis for the short-term reforms was conducted in two steps. Firstly, a set of unbalanced panel models was estimated for all gathered indicators from the World Bank (2014) that were analyzed as potential determinants of the labor law reforms. During that step for all independent variables the indices of a year to year change were calculated and were added to the data set⁵. Secondly, for the selected variables that occurred to be significant in the first step two balanced data set were constructed⁶, which allowed to perform the final analysis. One of the balanced data set comprised all significant variables, but at the cost of relatively small number of observations, while in the second one a few variables were dropped, which substantially increased the number of observations. Such an approach allowed also to verify the results with different data sets.

The models were estimated as the *pooled, fixed effects* (the within estimator) and *random effects* (Swamy & Arora, 1972)⁷. The decision which model type should be used was based on the Breusch-Pagan and Hausman tests. It was decided to use the estimator of the covariance matrix proposed by Arellano (1987), which is designed to handle both heteroskedasticity and autocorrelation in the data sets consisting of many units observed in relatively few periods. The variables were not logarithmically transformed, which is not a rare approach in empirical analysis concerning the labor market institutions (Nickell, 1997; Cazes & Nesporova, 2003; Lehmann and Muravyev 2012). It should be added that the models reestimated with

⁵ Thus all analyzed indicators were expressed both in levels and in indices.

⁶ Singular missing values for particular variables were filled with linear interpolation. However, if the multiple missing values were noticed, it was decided to drop the particular country or year from the data set.

⁷ The models were also estimated with the use of the system GMM estimator (Arellano & Bover, 1995; Blundell & Bond, 1998). However, it occurred that in all estimated models the lagged values of the dependent variable were insignificant, therefore it was decided not to use the GMM estimator. Moreover, obtaining such results limits the potential problems with endogeneity.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

the logarithmically transformed variables led to the same conclusions, albeit their fit to the data occurred to be generally worse.

For the theoretical models do not specify accurately which indicators should have decisive impact on the labor market reforms, in the preliminary analysis a broad set of various variables, characterizing mainly the situation on the labor market and different economic shocks, was employed into the analysis. Many of them occurred to be insignificant. The group of irrelevant variables comprised of: labor force participation rate, unemployment rate, youth unemployment rate, age dependency ratio (separately for younger and older dependents), employment to population ratio, GDP *per capita*, consumption expenditure, exports of goods and services, current account balance, foreign direct investments, market capitalization, and central government debt.

Table 1. Description of variables presented in the econometric analysis.

Variable	Short description	Obs.
Dependent variable		
<i>yy_LFI</i>	A year to year change in the Labor Freedom Index	1487
Independent variables		
<i>LFI</i>	The Labor Freedom Index (scale 0-100)	1667
<i>yy_world_LFI</i>	A year to year change in the global average of the Labor Freedom Index	9
<i>u</i>	Unemployment rate (ILO estimate, alternatively national estimate)	1524
<i>emp_ind</i>	Employment in industry (% of total employment)	835
<i>u_long</i>	Long-term unemployment (% of tot. unemp.)	544
<i>neet</i>	Share of youth not in education, employment or training (% of youth population)	371
<i>yy_gdp</i>	A year to year change in GDP (constant 2005 US\$)	1760
<i>market_cap</i>	Market capitalization of listed companies (% of GDP)	959
<i>gov_exp</i>	General government final consumption expenditure (% of GDP)	1535

Note: a prefix 'yy_' before the variable name means that it is an index of the year to year change of that variable, where previous year = 100.

Source: own elaboration based on the Heritage Foundation (2014) and World Bank (2014).

**Proceedings of the 8th International Conference on Applied Economics

18-19 June 2015, Economics and Finance**

Surprisingly, only a few analyzed variables occurred to be significantly correlated with the year to year changes in the Labor Freedom index. The selected results for these variables are presented in Table 2, 3 and 4, where as their short description is shown in Table 1.

The results of the unbalanced panel estimation (Table 2) confirm that in the analyzed period more countries decided to strengthen their labor protection legislation. It is indicated by the negative and significant parameter for the *LFI* variable. It informs also that the higher the level of labor freedom was, the greater was the pressure to limit it. A surprising result was obtained for the unemployment rate which occurred to be insignificant determinant of labor law reforms. As far as the GDP growth is concerned, it was found that the better the economic situation is, the stronger the tendency to liberalize labor regulations (Model 2). Although such a result is in line with previously derived conclusion (see Figure 1), it has to be stated that this relationship loses its significance if the *LFI* and *yy_world_LFI* are added to the model (Model 3).

Source: own estimates.

Moreover, adding the measure of the market capitalization, which can also be seen as an indicator of the current economic situation, did not help to explain the scale of labor law reforms. Interesting results were obtained for the *neet* and *u_long* variables. They indicate that the higher the group of excluded (or nearly excluded) from the labor market is, the greater the pressure to liberalize the labor law. However, this conclusion is in fact limited mainly to the highly developed countries due to the large amount of missing values for developing countries for the *neet* and *u_long* variables.

The results for the first balanced panel data set that consists of 96 countries and 768 yearly observations are presented in Table 3. It can be noticed that Model 7 has the same set of variables as Model 8 (the same applies to Model 10 and 11), which is a consequence of the fact that the Breusch-Pagan and F tests gave unequivocal results concerning the need to introduce dummy variables for the countries. The results obtained for this panel also did not indicate that changes in GDP are significant determinants of the changes in the Labor Freedom index. Model 12 indicated that the market capitalization of listed companies could be an important factor, however this relation was not confirmed by other models. Different conclusions can be derived for the government expenditure. The estimates indicate that the higher these expenditures are, the stronger is the pressure to strengthen the labor protection. Probably, changes in both variables can be seen as two elements of the same decision. In reaction to an adverse shock the government might both increase the public spending and strengthen the labor protection.

The results for the second balanced panel that consists of 37 countries and 296 observations are presented in Table 4. Here also some equations

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

are presented for two different estimators due to the unequivocal results for the Breusch-Pagan and F tests. Quite surprisingly, the previously derived conclusions concerning the government expenditure and excluded groups from the labor market did not find confirmation in this reduced data set. It may indicate that previously identified relationships have heterogeneous relevance for different groups of countries. Such a result is less surprising if it is remembered that (and as the literature suggests) the impact of the analyzed determinants may be dependent on the political strength of particular groups on the labor market and also on the government's preferences and determination. All these political factors are not directly observed (especially globally), therefore it was not possible to analyze their potential interactions with the identified determinants. However, it may be concluded that these factors play different role in particular countries, which in consequence led to obtaining unequivocal results.

Source: own estimates.

The results presented in Table 4 indicate however, that the level of employment in industry (as a percentage of total employment) and changes of that level can be important determinants of labor law reforms. Probably, the theoretical analysis conducted by Boeri (2005) can help to explain this relationship. A stronger industry sector should result in greater exposure to supply shocks. Thus, positive supply shocks lead to higher forgone efficiency (when the labor regulations are not changed), which causes pressure to liberalize the labor law. This liberalization is, however, opposed by the industry workers. Therefore, it is not surprising that increase in the number of these workers provides them with greater political strength and may result in reinforcement of their protection.

Conclusions

The aim of this research was to identify determinants of the employment protection legislation reforms around the world. Critical analysis of the literature indicated that macroeconomic shocks could be incentives to these

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

reforms, especially the adverse shocks (that worsen the situation on the labor market). However, also the positive supply shocks can trigger the reforms, because the increase in labor productivity causes that current employment protection regulations result in higher forgone efficiency. However, these incentives may lead to different governmental decisions, since the government also has to include the political pressure from various interest groups on the labor market, especially the employees. In consequence, the initiated reforms can have various scope, time of implementation and even different direction.

The empirical analysis was conducted for 179 countries with the use of the Labor Freedom index published by the Heritage Foundation. The initial analysis of the collected data revealed that governments less often decide to conduct reforms that relax the employment protection. However, when the reforms are initiated, they are usually deeper than the typical changes that increase the level of that protection. It was also found that in years 2006-2009, when the world economic situation was promising, most governments decided to liberalize the labor law. However, this tendency was reversed in reaction to the global recession in 2009 when governments generally decided to strengthen the protection of employees.

The econometric investigation allowed to identify a few indicators that can initiate the labor law reforms. It was found that changes in GDP and the level of employment in industry may be such factors. Labor law reforms may also depend on the number of the nearly excluded from the labor market (long-term unemployed and the youth not in education, employment or training). The changes in employment protection also occurred to be correlated with changes in the government expenditure.

However, these results were not confirmed in all models, which may be a consequence of omitting potentially important factors, i.e. the political strength of particular groups on the labor market and the determination of government to implement the reforms, because they are not directly observable. The low level of the coefficient of determination in almost all estimated equations indicates that these omitted factors may play a substantial role in explaining the changes in the labor law. Therefore, there is a need to continue the research in this field, especially in order to assess the strength of political factors that may affect the labor market reforms. It is also advised to continue these analyses with the use of other indicators of labor market institutions in order to verify conclusions obtained in the presented research.

**The Question of State Aid for Rescuing
and Restructuring Undertakings in Difficulty in
the Context of the General Government Sector
Debt of EU Member States***

JEL Classification: *E62; K20; K33.*

Keywords: *the European Union; legal regulation; rescue and restructuring aid; the general government sector debt; financial and economic crisis*

Abstract: The subject of the article is an analysis of the rules of state aid admissibility on the basis of the implementing regulations, adopted by the European Commission in 2004 and 2014 on rescue and restructuring aid. This should lead to verify the thesis that due to the taken up at EU level – in response to the effects of the financial and economic crisis – economic recovery plan, the support of the public authorities directed at rescuing and restructuring undertakings in difficulty has become the most broadly used form of State aid due to the value among all the forms of aid granted by Member States of the European Union. The adoption of such a thesis raises the question of the influence of State aid on the size of the *general government* sector debt in the EU Member States, which have provided State aid for undertakings in difficulty. This analysis was carried out based on the linear regression model. The response variable (dependent variable Y) is the size of the *general government* sector debt, and explanatory variable (independent variable

X) is the expenditure on State aid. The research shows that between expenditures of the EU Member States on aid for rescuing and restructuring undertakings in difficulty and the condition of the public finances of these countries there is no substantial statistical relationship. Taking this into consideration the most important question arises. Does the State aid "to prevent the bankruptcy of undertakings" follow the condition of art. 107 par. 2 point c of Treaty on the functioning of the European Union?

Introduction

The crisis in the financial markets, which began in 2007, in a short time began to significantly affect the real economy. This effect could be observed by a strong downward turn in the overall economy, which affected directly both households and undertakings. The result of the financial crisis in the banking sector in the Member States of the European Union was the process carried out by banks of reducing own debt relation to equity capital. Banks have therefore become less willing to take risk comparing to the previous years, which in turn led to reduced availability of credits as a source of financing for undertakings and reduce the number of credits in general. This trend had negative consequences not only for enterprises that did not have adequate financial security in case of insolvency, but even for enterprises with good and stable financial condition, which were suddenly reduced the credit line or denied the credit. Taking into account that affordable and sufficient access to finance is a prerequisite for undertakings in making investments and creating new jobs, it should be noted that a restrictive credit policy affected mainly small and medium-sized enterprises, which access to financing is more difficult compared with large enterprises. Hence, in this economic situation State aid granted by the Member States started to be an important complement of efforts to unblock credits for enterprises.

The financial crisis ended a period in the European Union of economic growth, low intensity of granted State aid and decreasing budget deficits as well as declining unemployment rate (compare Hallerberg, 2011). On 26 November 2008 the European Commission adopted a statement titled "The European economic recovery plan" (EC, 2008) talking about how to get Europe out of the financial crisis. This plan, which was based on two interdependent components, assumed a more intense and faster implementation of reforms already underway under the Lisbon Strategy. The first is the short-term measures to increase demand, job protection and restore confidence to financial institutions, and the second is "smart investments",

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

which in the long run were to ensure a higher growth rate and sustainable economic growth. Economic recovery plan also contained proposals on the application of State aid rules in a way that achieves maximum flexibility for tackling the crisis while maintaining equal conditions for all enterprises and avoiding excessive restriction of competition.

Taking into consideration that the consequence of the financial crisis affecting the restriction of access to finance and the crisis in the real economy which leads mainly to a decline in production is a crisis of excessive public debt and budget deficit resulting from the slowdown in the various fields of economy, the purpose of this article is to analyze the conditions of admissibility of State aid for rescuing and restructuring undertakings in difficulty. This should lead to verify the thesis that due to the economic recovery plan taken by the European Union, the implementation of which would result in a reduction in the social costs of the economic downturn, stimulating demand and strengthening consumer confidence, as well as supporting innovation, building a knowledge-based economy and quicker transition to a low-carbon and efficient in terms of resource use economy, the support of the public authorities directed at rescuing and restructuring undertakings in difficulty has become a form of State aid the most widely used due to the value from all forms of aid provided by Member States of the European Union. The adoption of such a thesis raises the question of the influence of State aid on the size of the *general government* sector debt in the Member States, which have provided aid to enterprises in difficulty. It is possible – with a certain simplification - to accept that since the premise of granting such aid is prosperity and increase of the competitiveness of the European Union, such aid should have a positive impact on public finances, as the expenditure on this aid will be offset by a strong reduction of operational aid granted to cover current cost of the enterprise activities as well as budget revenues from taxes and other public levies paid by effectively functioning, restructured enterprises. Thereby, it will be possible to say that the amount of expenditure on State aid to undertakings in difficulty for the whole European Union and particular Member States should be negatively correlated with the size of the *general government* sector debt. The negative correlation of the size of the *general government* sector debt with the amount of expenditure on State aid for rescuing and restructuring undertakings would mean that with increasing amount of State aid to enterprises in economic difficulty the *general government* sector debt of Member States providing such aid should decrease.

Methodology of the research

A feature of applied research method is the analysis of the intervention instruments used by the State from the point of view of concepts of State aid within the meaning of art. 107 par. 1 of the Treaty on the functioning of the European Union (TFEU - OJ 2010 C 83/1). The adoption of such a method provided an opportunity to: firstly, determining the semantic scope of admissibility and the rules of providing aid as interpreted by the Court and the Court of Justice of the European Union, and secondly - capturing the specific characteristics of State aid for enterprises in difficulty. Another feature of the method used in the paper is the analysis of the relation between the Member States expenditure on State aid designed for rescuing and restructuring undertakings in difficulty and the size of the *general government* sector debt of these countries. This analysis was carried out in accordance with the linear regression model. The response variable (dependent variable Y) is the size of the debt of the *general government* sector and the explanatory variable (independent variable X) is the expenditure on State aid.

Statistical analysis was carried out based on three source tables. The first and second table show the calculations for the linear regression model concerning respectively the intersection parameter (free term α) and slope parameter (directional factor β). The factors a and b of the regression function II are the estimators of the parameters α and β of regression function I (Bielecka, 2011, pp. 279-281). The standard error S_a is the standard error of the estimator a of the parameter α , whereas the standard error S_b is the standard error of the estimator b of the parameter β . The designations "Lower 95%" and "Upper 95%" concern lower and upper limits of so-called confidence interval of numerical values for parameters α and β , where these parameters are with a probability of 95%.

t Stat is a test of linear relationship occurrence between expenditure on State aid to enterprises in difficulty and the size of the *general government* sector debt. This statistical test allows to verify the authenticity of the so-called null hypothesis that the parameters of the regression function I type α and β are equal to zero, with the alternative hypothesis that they are not equal to zero ($H_0: \alpha = 0$; $H_A: \alpha \neq 0$ and $H_0: \beta = 0$; $H_A: \beta \neq 0$). The acceptance of the null hypothesis that the parameter $\alpha = 0$ would mean that if the expenditure on State aid are zero (State aid does not exist), then the value of the *general government* sector debt will also decrease to zero. In turn the acceptance of the null hypothesis that the parameter $\beta = 0$ would

mean that the increase in the value of expenditure on State aid by € 1 million will not cause any changes in the size of the *general government* sector debt which means the lack of any relationship between expenditure on State aid and the size of the *general government* sector debt. In other words, the acceptance of the null hypothesis means the lack of the influence of the State aid for rescuing and restructuring undertakings provided by the Member States of the European Union on the size of their *general government* sector debt. From the perspective taken in this paper it will be essential to reject the null hypothesis in favor of the alternative hypothesis which states that between the studied phenomena - expenditure on State aid and the size of the *general government* sector debt - there is a significant statistical relationship. From the tables of critical values of t-Student it is seen that $\pm t_{\alpha/2} = \pm 2.5706$ for $\alpha = 0.05$ and $n - 2 = 5$ degrees of freedom. The null hypothesis can be rejected in favor of the alternative hypothesis only when $t_b < t_{\alpha/2}$ or $t_b > t_{\alpha/2}$, that is when $-t_b < -2.5706$ or $+t_b > +2.5706$.

The p -value is the probability of making so-called type I error, involving the rejection, based on the results of the test, of the hypothesis that assumes the values of the parameters α and β are equal to zero, when in fact they are equal to zero in the whole population. In other words, type I error is a rejection of a real null hypothesis. The higher the value of the t-test means the lower the probability of type I error. In general, it is assumed that if the p -value is less than 0.05, the null hypothesis can be rejected in favor of the alternative hypothesis, and thus claim that there is a statistically significant relationship between the expenditure of EU Member States on State aid directed at enterprises in difficulty and the size of the *general government* sector debt of these countries.

The third table contains regression statistics. Among the regression statistics are: the correlation coefficient, determination coefficient, standard error and the parameters of F test, that is the value of F-test and the probability of making type I error, when the hypothesis is verified concerning the lack of impact of expenditure on State aid on the size of the *general government* sector debt (irrelevance of State aid expenditure in the regression model). F-test, similarly as described above t-test, is used for testing the significance of linear regression coefficient β evaluation. The checking of this test is a statistic F having F-Snedecor distribution of k_1 and k_2 freedom degrees. When rejecting the null hypothesis $F > F_{\alpha}$ of no relation between expenditure on State aid and the size of the debt of the *general government* sector and accepting the alternative hypothesis of the existence of a statisti-

cally significant relationship between the variables. From the table of critical values of the F-Snedecor for $k_1 = 1$ (1 independent variable) and $k_2 = n - 2 = 5$ degrees of freedom and $\alpha = 0.05$ we read $F_{0,05} = 6.608$. Thus, the alternative hypothesis can be adopted only when $F > 6.608$.

Economic justification for intervention in the Internal Market mechanisms

From the economic point of view relating to state interventionism it ought to be noted that State aid can be a justified action mainly because of the social prosperity if free competition market mechanism does not bring satisfactory results. In this case, a well-planned state intervention may improve the allocation of production factors, reduce the irregularity in the market functioning and enable the achievement of common interest. The major criterion for providing State aid should be rationality, which is the highest determinant of the admissibility of using the aid measures. It results from the fact that in a market economy the competition is essential for the proper functioning of the market and protecting the interests of its participants. State aid should not violate it unless its violation will be compensated by positive market phenomena that were caused by providing the aid. With the use of the aid instrument the State realizes the objectives that are considered a priority for socioeconomic development.

In the market of the European Union, which is based on the mechanism of free competition, many changes occur as a result of the impact of micro-, meso- and macroeconomic factors. On the one hand, these changes go together with positive effects in the form of the development of the enterprises, both those already operating in the Internal market as well as those whose strategic goal is to enter the market and do business activity in the long term. Compliance with the principles of free competition, reduction of the entry barriers, elimination of customs barriers, consistent combating monopolistic practices, the inflow of direct foreign investments and the related production increase, creating the conditions for public procurement and the suppliers endeavour for uniform purchase prices and purchasing the products at prices adopted in the country where they are the lowest, they are the desired effects of competition in the Single European Market, enabling economic and social development of the European Union (Adamkiewicz-Drwiłło, 2010, p. 58). On the other hand, not all market processes can be considered as the desired effect of competition. Then it is indicated, that the market economy, in which the primary regulator of the occurring pro-

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

cesses is the competition, is burdened with certain deficiencies. The deficiencies of the market system are in such a situation justification for a replacement or supplement based on free competition of the market mechanism by other decision making processes, such as the State intervention.

The existence of market inefficiencies makes the assumptions, on which the model of the perfect competition is made, not always fulfilled, and thus it becomes difficult to achieve overall balance as well as maximize total prosperity. In other words, the lack of optimal market efficiency in the Pareto sense may justify the state interventionism with the object of ensuring the optimal allocation of resources. Therefore, the market inefficiencies justify the State intervention and legitimize public authorities to adopt specific legal, administrative and economic regulations within the scope of aid for enterprises, however it is important to remember of such balancing of the size of provided aid so as the negative consequences do not bring more harm to entities functioning in the market. The actions taken by the State aimed at correcting the market failures within the scope of the intervention in economic processes can also be ineffective due to the probability of government failures. At this point the failure of the state is shown, associated with its role as a remedy to the problem of information asymmetry and coordination of supply and demand, which means that the state actions to encourage improvements in efficiency and allocation of market mechanism are subject to failures and as a result can lead just as the market mechanism to inefficient allocation of resources (Demsetz, 1969). This means that the State intervention in the economy is basically justified only in the occurrence of market imperfections, even then there is no guarantee that the measures used by the state will lead to greater prosperity, which is due to the lack of possession by the public authorities of the necessary information or high cost of the use of appropriate measure of aid. However, even if the State has the necessary information and relevant financial resources and intervenes in order to promote the market mechanisms and economic growth, the control of these interventions can not be avoided at the supranational level. This is because even the legitimate actions taken by the given state within the interference in economic processes can cause harmful side effects in other countries (Nicolaidis, 2004, pp. 365-396). Hence, due to the impact that the provided aid has on the economic interests of enterprises that are beneficiaries, and also their competitors, and the economy of individual countries, the issues relating to the admissibility of the aid are precisely regulated within the European Union. The rules adopted at EU level affect the national regulations that relate to the provision of aid itself (see

**Proceedings of the 8th International Conference on Applied Economics

18-19 June 2015, Economics and Finance**

Hille & Knill, 2006; Toshkov, 2008; König & Mäder, 2013; Böhmelt, 2013). They answer the question of whether the aid designed by a Member State, legal in the light of its national law, may be considered as compatible with the objectives of the European Union and whether it can be given? These principles are addressed to the Member States and are designed to eliminate the aid which has negative impact on competition and trade within the Internal market, and in cases where such aid must be exceptionally provided – discipline of these countries and standardizing the conditions within the EU that must be fulfilled in order for aid to be provided, which in turn should minimize its negative effects.

**Admissibility of State aid for rescuing and restructuring
undertakings in difficulty**

State aid for rescuing and restructuring enterprises is without a doubt one of the most controversial cases of financial support provided by the State, which considerably affects the distortion of competition and trade within the European single market (Nicolaidis & Kekelekis, 2005, pp. 17-26). The only legal basis on which the aid for undertakings in difficulty can now be regarded as admissible is art. 107. par. 3 point c) of the Treaty on the functioning of the European Union (TFEU). According to this provision the European Commission has the power to authorize "aid to facilitate the development of certain economic activities or of certain economic areas, if [the aid] does not affect trading conditions to an extent contrary to the common interest". This case may take place in particular when the aid is necessary to correct disparities caused by market failures or to ensure economic and social cohesion. Therefore providing the aid to the economic entities in this field can be regarded as legitimate only under certain conditions. This aid may be justified, for example, due to the applied social or regional policy, because of the need to take into account the advantageous role fulfilled by small and medium-sized enterprises in the economy or, exceptionally, due to the need to maintain the competitiveness on the market at a time when the liquidation of enterprises in difficulty could lead to create a monopoly or clear oligopoly on that market. On the other hand, in any case, it is not justified to artificially support of the activity of the enterprise in a sector characterized by long-term and structural overproduction or the enterprise whose survival depends only on repeated state interventions.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

The existing rules for granting aid to undertakings in difficult economic situation were largely based on the practice of supporting the steel sector in Europe in recent decades. In article 4 point c of the Treaty establishing the European Coal and Steel Community it was specified that any State aid is incompatible with the common market of coal and steel (ECSC - Treaty of Rome, 1957). In practice such a provision would mean that State aid is prohibited within the Community. This provision however proved to be too far-reaching and, consequently, granting of certain types of aid was allowed, recognizing them as the community aid – it mainly concerned State aid for the mining sector in order to secure energy supplies in the Community. The first report on Competition Policy of 1971 stated that the European Commission will not, as a rule, oppose granting aid by the Member States to enterprises in difficulty, if such aid will be used in exceptional circumstances and on the basis of clearly specific program of reorganization, so that it becomes a real contribution to the reorganization of their respective enterprises or regions (Anestis & Mavroghenis & Drakakakis, 2004, p. 27). Basing on the experience gained the European Commission announced in subsequent reports on competition policy more detailed rules for granting aid to undertakings in difficulty (compare Borghetto, 2014). As a result the conditions of admissibility of State aid directed at rescuing and restructuring of enterprises in difficulty were determined in the appropriate community guidelines adopted in the form of communications from the European Commission.

The Commission adopted its original Guidelines on State aid for rescuing and restructuring undertakings in difficulty in 1994 (OJ C 368, 23.12.1994, p. 12). In 1997, the Commission added specific rules for agriculture (OJ C 283, 19.9.1997, p. 2). A modified version of the guidelines was adopted in 1999 (OJ C 288, 9.10.1999, p. 2). In 2004 the Commission adopted new guidelines (OJ C 244, 1.10.2004, p. 2), the validity of which was first extended until 9 October 2012 (OJ C 156, 9.7.2009, p. 3) and subsequently until their replacement by new rules (OJ C 296, 2.10.2012, p. 3) in line with the reform programme set out in the Commission Communication of 8 May 2012 on EU State aid modernisation (EC, 2012). From 1 August 2014 the provisions entered into force of the new guidelines on State aid for rescuing and restructuring non-financial undertakings in a difficult situation (OJ C 249, 31.7.2014, p. 1), which introduces some changes, most favorable to the beneficiaries - e.g. temporary restructuring support.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

European Commission guidelines clearly indicate that aid for rescuing and restructuring undertakings in difficulty can be granted only to enterprises in difficulty. An enterprise in difficulty is the business entity which using its own funds is not able to reduce the growing negative financial result and without outside intervention of public authorities is not able to function in the short or medium term. According to the guidelines of the European Commission in 2004 - on the basis of which Member States granted State aid both before the financial crisis and already in the period of its duration - the undertaking was considered to be at risk in the following circumstances:

- where more than half of the registered capital has been lost including more than one quarter of that capital over the preceding 12 months (a limited liability company, joint stock company), or when more than half of the company's capital according to the financial statement has been lost, including more than one quarter of the preceding 12 months (personal trading company and a civil partnership);
- if the criteria of the national law were met concerning collective insolvency proceedings (regardless of the type of company).

The enterprise was also regarded as a threat, if there are premises indicating loss of financial liquidity, such as increasing losses in the current activity, diminishing turnover, growing stock inventories, excess capacity, declining cash flow, mounting debt, rising interest charges and falling or nil net asset value. In each of these cases an enterprise in difficulty was eligible for aid only if it clearly could not regain financial liquidity through its own resources and, in some justified cases, through resources obtained from the shareholders or from market sources.

The previous definition of "undertaking in difficulty" contained both so-called "hard" (objective) criteria and "soft" criteria which required a broader and more subjective assessment of the undertaking's situation. To improve clarity and legal certainty, the new guidelines aim to shift the emphasis from soft to hard criteria, making it easier for granting authorities and potential aid beneficiaries to determine whether a given undertaking is in difficulty. The soft criteria are therefore reduced to a residual category that will apply only in exceptional circumstances. To keep the coverage of the definition approximately the same overall, the new guidelines balance the reduction in the scope of the soft criteria by introducing new hard criteria. Therefore, an undertaking is considered to be in difficulty if at least one of the following circumstances occurs:

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

- a) in the case of a limited liability company (Annex I, OJ L 182, 29.6.2013), where more than half of its subscribed share capital has disappeared as a result of accumulated losses. This is the case when deduction of accumulated losses from reserves (and all other elements generally considered as part of the own funds of the company) leads to a negative cumulative amount that exceeds half of the subscribed share capital.
- b) in the case of a company where at least some members have unlimited liability for the debt of the company (Annex II, OJ L 182, 29.6.2013), where more than half of its capital as shown in the company accounts has disappeared as a result of accumulated losses.
- c) where the undertaking is subject to collective insolvency proceedings or fulfils the criteria under its domestic law for being placed in collective insolvency proceedings at the request of its creditors.
- d) in the case of an undertaking that is not an SME, where, for the past two years:
 - 1. the undertaking's book debt to equity ratio has been greater than 7,5 and
 - 2. the undertaking's EBITDA interest coverage ratio has been below 1,0.

New guidelines from 2014 do not contain an indication that the quarter of enterprise capital loss must have occurred within the preceding 12 months.

Community guidelines of 2004 distinguish between two types of aid to enterprises in difficulty, i.e. aid for rescuing and aid for restructuring. EU guidelines of 2014 distinguish additionally third type of aid - temporary restructuring support.

Rescue aid

Rescue aid for undertakings in difficulty is a support which is by nature temporary and reversible, which is focused on maintaining financial liquidity of unprofitable enterprise for the time to develop a plan for its restructuring or liquidation. The general principle is that rescue aid makes it possible to provide temporary support to an undertaking facing a serious deterioration of its financial situation, involving an acute liquidity crisis or technical insolvency. Such temporary support should allow time to analyse the circumstances which gave rise to the difficulties and to develop an appropriate plan to remedy those difficulties.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

Rescue aid cannot be longer than six months, is repayable and is admissible in the form of credit guarantees or loans with an interest rate comparable to loans for enterprises in good financial condition, including, in particular, with an interest rate comparable to the reference rates published by the European Commission (OJ C 14, 19.1.2008, p. 6). Within six months from the moment of granting the aid the Member State has three possibilities of action: 1) it shall notify the enterprise restructuring plan to the European Commission; 2) it shall submit a plan of liquidation of the enterprise; 3) it shall provide proof of full repayment of the loan or proof of termination of the guarantee validity. New guidelines of 2014 show that the amount of admissible rescue aid must be limited to the minimum. Rescue aid must be restricted to the amount needed to keep the beneficiary in business for six months.

It should be noted that the rescue aid is a one-off operation designed to keep functioning of the undertaking in a certain period of time, in which its chances will be assessed concerning continuing existence in a given market - i.e. the principle of *one time last time* (Mehta, 2009, pp. 216-217). In the situation when the rescue aid is granted to an enterprise that has already received restructuring aid, it can be considered that the beneficiary's difficulties are of lasting and stable nature and frequent state interventions cause distortions of competition, which is contrary to the principles set out in the TFEU of State aid admissibility. Repeated granting of rescue aid essentially misses the principle when it only comes to the shift in time of inevitable liquidation of the enterprise. Therefore, in order to avoid unfair provision of aid to the undertakings that can survive on the market only by repeatedly granted State aid, rescue aid should be granted only once. In turn, the responsibility of the Member State intending to provide emergency aid should be submitting to the European Commission the necessary documentation which shows if the potential beneficiary used in the past ten years of this type of aid. In addition, the application of the principle of "first and last" is in no way affected by the ownership changes of the enterprise following the granting of aid and any administrative or judicial procedures, aimed at "healing" the balance sheet, reducing liabilities or cancelling previous owner debts.

Restructuring aid

From the moment in which the restructuring or liquidation plan of enterprise in difficulty has been established and is being implemented, every

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

additional aid will be considered as aid granted for the purpose of restructuring. The purpose of restructuring aid is to restore the long-term profitability of the undertaking. Restructuring may involve one or more of the following elements: the reorganisation and rationalisation of the beneficiary's activities on to a more efficient basis, typically involving withdrawal from loss-making activities, restructuring of those existing activities that can be made competitive again and, possibly, diversification towards new and viable activities. It typically also involves financial restructuring in the form of capital injections by new or existing shareholders and debt reduction by existing creditors. It should be however noted that restructuring processes cannot be limited only to financial aid which will compensate the losses without identifying and removing the causes of their occurrence. The restructuring plan which duration must be as short as possible, must accurately describe the circumstances that led to the company's difficulties, thereby providing a basis for assessing whether the proposed measures are appropriate. In addition the restructuring plan should include the analysis of the current status and forecasts concerning changes in demand and supply in the market, taking into account situations based on the best, and the least favorable and intermediate assumptions and the specific weaknesses and strengths and of the enterprise. This plan must also provide such a change in the situation of enterprise, which after the completion of the restructuring processes will allow it to cover all costs including amortization and other charges.

The amount and intensity of restructuring aid must be limited to the strict minimum necessary to enable restructuring to be undertaken, in the light of the existing financial resources of the beneficiary, its shareholders or the business group to which it belongs. In particular, a sufficient level of own contribution to the costs of the restructuring and burden sharing must be ensured. Such assessment will take account of any rescue aid granted beforehand. The European Commission expects the beneficiaries of the aid that a substantial contribution to the restructuring plan will come from their own resources, including the sale of assets that are not essential to the continued existence of the undertaking. Contributions must be real, that is to say actual, excluding future expected profits such as cash flow, and must be as high as possible. The minimum contribution is at least 25% for small enterprises, 40% for medium-sized enterprises and 50% for large enterprises. In order to limit the distortive effect, the amount of aid or the form in which the aid is granted cannot provide the company with the surplus cash, which can be used for speculative activities distorting competition in the

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

internal market. Therefore the Commission shall make a thorough analysis of the enterprise liabilities after the restructuring, taking into account primarily financial situation after each postponement or reduction of its debts. In the case of restructuring aid to small and medium-sized enterprises it is sufficient to forward each year a copy of the balance sheets and profit and loss account of the aided enterprises. In the case of aid granted to large enterprises, the Commission shall require providing confirmation of the proper way of implementation of the restructuring plan through regular detailed reports transmitted by the Member State concerned, which contain all the necessary information on the stages of the implementation of restructuring program, the schedule of payments of subsequent tranches for the enterprise and its current financial situation and to comply with all conditions and obligations laid down in the decision approving the aid.

The previous guidelines has required undertakings that are being restructured to make a contribution to the restructuring costs from their own resources. This "own contribution" rule has helped to limit the amount of aid to the minimum necessary. However, it has lacked the precision needed to ensure that the costs of restructuring are distributed fairly among investors and taxpayers. In dealing with State support to banks during the crisis, the Commission developed a more targeted approach in this respect, using the concept of "burden sharing". This concept looks not only at the amount of own contribution, but also at who is providing that contribution. In particular, since the high returns that shareholders obtain when a enterprise is performing well are balanced by the risk of losses that they bear, there is no justification for expecting taxpayers to bear losses in place of shareholders.

Another issue, which therefore required more detailed regulation was the sharing of the burden between current investors. The draft guidelines of 2014 contained two possible approaches to this question. Option 1 took a more broad-brush approach by requiring that the contributions made by incumbent shareholders and creditors should be reasonable in view of the likely losses that they would have suffered in the event of insolvency. Option 2 was more precise, requiring first that all past losses be borne by shareholders and then, if that is not sufficient, that subordinated creditors also contribute. Finally the principle of adequate burden sharing was accepted, according to which incumbent shareholders and, where necessary, subordinated creditors must absorb losses in full. Subordinated creditors should contribute to the absorption of losses either via conversion into equity or write-down of the principal of the relevant instruments. Therefore, State intervention should only take place after losses have been fully ac-

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

counted for and attributed to the existing shareholders and subordinated debt holders.

Admissibility of restructuring aid depends on taking appropriate compensatory measures to avoid excessive distortions of competition. Aid for undertakings in difficulty cannot be treated in terms of "automatic mechanism", where its operation will be based on the principle: "if necessary - the State will intervene and grant appropriate support". The possibility of receiving unconditional State aid in the event of a threat of bankruptcy on the one hand can lead to excessive risk-taking, on the other hand, however, such aid may mean rewarding those enterprises that have the latest adapt to changing market conditions. Compensatory measures are intended to provide a kind of renunciation for the enterprise benefiting from State aid, the price for the opportunity to remain on the market. It is most often the appropriate reduction of capacity. The reasoning behind this requirement is, however, more difficult in a situation where on a given market there is no excessive production capacity. In this case, production capacity limitation of the undertaking which is a recipient of the State aid will in the short term cause the shortage of production capacity on a given market and, consequently, decrease the supply of the goods and increase of prices. In the long term, assuming that the market is a competitive market and is not characterized by a very low price elasticity of supply, the balance will be restored, because the most effective competitors, adapting to changing market conditions by lowering costs and increasing productivity, will fill the gap on the market.

Condition for implementation of compensatory measures would not be normally applied to small enterprises, since it can be assumed that *ad hoc* aid to small enterprises generally do not distort competition to an extent contrary to the common interest. Generally speaking aid for small and medium-sized enterprises have a lesser effect on trading conditions than aid granted to large enterprises. Hence the plan of restructuring small or medium-sized enterprise is not subject to individual notification and notification by the European Commission, but only to approval by the Member State concerned (Quigley, 2009, p. 311). Whereas any rescue aid to granted for more than six months, or stopped after a period of six months must be individually notified to the Commission. Aid schemes for rescuing and restructuring aimed at small and medium-sized enterprises must specify the maximum amount of aid that can be granted to each enterprise, taking into account possible changes in the restructuring plan. The maximum amount of aid granted in total for rescuing and restructuring undertakings may not be

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

more than € 10 million, and if it is exceeded it shall be individually notified to the European Commission. In addition Member States are required to individually inform the Commission of the aid granted to the enterprise, which took over the assets of another, already supported for rescuing and restructuring, enterprise.

The tangible result of the restructuring processes carried out should be a significant reduction or complete cessation of activity by the undertaking. It results from the fact that the decrease in market share is necessary to achieve the intended efficiency and rationality of management, regardless of the reduction of production capacity. However these savings lead to a reduction in employment in the restructured enterprise. Therefore the aid is additionally distinguished to cover the social costs of restructuring. Beside covering the costs of redundancy payments and early retirement, this aid includes special restructuring schemes through training, counseling and practical help with finding alternative employment, aid in moving, as well as professional training and assistance for employees who want to run their own business. Given that such measures, which increase the employability of redundant workers, further the objective of reducing social hardship, the European Commission consistently takes a favourable view of such aid when it is granted to undertakings in difficulty.

Temporary restructuring support

The previous guidelines have treated all forms of restructuring aid alike: loans, guarantees, capital injections, debt waivers and even outright cash grants. However, liquidity assistance (loans and guarantees) that is limited in both amount and duration is less distortive than other forms of aid, since it does not go beyond what is needed to address the liquidity problems that are commonly the main obstacle to restructuring and since it must be repaid with interest. To simplify the provision of aid for restructuring, while also reducing distortions of competition, the guidelines of 2014 include a new concept of temporary restructuring support.

Temporary restructuring support is liquidity assistance designed to support the restructuring of an undertaking by providing the conditions needed for the beneficiary to design and implement appropriate action to restore its long-term viability. Temporary restructuring support may only be granted to SMEs and smaller State-owned undertakings. This kind of State aid may also be granted to undertakings that are not in difficulty but that are facing acute liquidity needs due to exceptional and unforeseen circumstances.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

Temporary restructuring support may be granted for a period not exceeding 18 months. Before the end of that period the Member State must approve a restructuring plan, or liquidation plan, or the loan must be reimbursed or the guarantee terminated. Recipients of temporary restructuring support do not have to submit a full restructuring plan, but they are required to provide a simplified plan that identifies the actions that they intend to take to restore their long-term viability.

Does the provision of State aid by the EU Member States for rescuing and restructuring enterprises in difficulty affect their *general government* sector debt?

Taking into account the rules of admissibility of aid for rescuing and restructuring undertakings in difficulty, the enterprise interested in receiving aid must comply with a number of conditions. While the rescue aid is a one-off operation, the aim of which is a temporary improving finances of the enterprise for the time needed to prepare a restructuring or liquidation plan, the restructuring aid is based on the specified plan to restore long-term profitability of the enterprise. Hence in the latter case, to get the support of the public authorities, the undertaking must provide a detailed recovery plan that describes how to return to financial liquidity and reduce the production, which is a form of compensation for other enterprises in the sector of the economy that did not receive State aid.

Table 1 shows the intensity of State aid provided for the purpose of rescuing and restructuring undertakings in the Member States of the European Union in 2007-2013.

Source: EUROSTAT.

In the analyzed period the total amount of aid for rescuing and restructuring, which in table 1 is presented jointly in a horizontal and sectoral manner, settled for the area of the EU-28 at € 679 million in 2007, € 617 million in 2008, € 1079 million in 2009, € 703 million in 2010, € 560 million in 2011, € 694 million in 2012 and € 504 million in 2013. On the basis of the data presented in table 2 it can be concluded that it corresponded to a share in the total amount of the State aid in these years respectively at the level: 1.20%, 0.96%, 1.58%, 1.11%, 0.98%, 1.20% and 0.92 %. Therefore, on the basis of available statistical data covering the period 2007-2013 it is difficult to positively verify the thesis adopted at the beginning of the article of a significant increase of the aid in the European Union for rescuing and restructuring enterprises in difficulty during the crisis.

Source: EUROSTAT.

Among nine Member States there can be noted a significant growth in the rescue and restructuring aid in 2008-2010, when the most intense anti-crisis measures were taken. These were: the Czech Republic, Greece, Spain, France, Italy, Hungary, Austria, Poland and Portugal. However, as in the case of the EU level, the increase in the absolute value of this kind of aid did not translate into a significant increase in relation to the total State aid, which resulted from an increase of the expenditures at the same time by the Member States on regional and horizontal aid.

In the so-called group of countries of "old fifteen", which have provided this kind of support to domestic entrepreneurs in the greatest amount there should be indication on Austria, Germany, the UK and Italy. These countries provided aid for rescuing and restructuring primarily to large enterprises of iron and steel sector (ThyssenKrupp - Germany, Arcelor - France)

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

and air transport (Alitalia - Italy, Olympic Airlines - Greece) and the automotive sector (Opel - Germany, Peugeot Citroen - France). However in the group of 13 countries that joined the European Union since 2004, the support provided in this direction is characteristic mainly for Poland, Romania and Hungary, and in most cases it is also sectoral aid. It should be noted that in the group of the EU-15 the upward trend of provided aid for rescuing and restructuring undertakings can now be pointed for Greece and the UK, and in case of the EU-13 countries the State aid to enterprises in difficulty in 2013 was increased by 3 countries: Malta, Romania and Slovenia.

Table 3 shows the size of the *general government* sector debt of EU Member States in the years 2007-2013. Bearing in mind that in the analyzed period the *general government* sector debt showed continuously a rising trend, it is difficult to mention the positive impact of State aid for rescuing and restructuring undertakings in difficulty on the condition of public finances of the Member States, as the size of the debt is fairly not reduced. Thus already at this point, we can reject the hypothesis set at the beginning of this article of a negative correlation of expenditures on State aid for rescuing and restructuring enterprises with the size of the *general government* sector debt. Does therefore the aid provided by Member States to enterprises in difficulty have an adverse effect on the condition of their public finances, leading to an increase in the *general government* sector debt? Or does such aid not have any impact on the *general government* sector debt? Answers to these questions will be provided by the regression analysis. Table 4 shows the test result for the sought relationship between the State aid for rescuing and restructuring undertakings in difficulty and the size of the *general government* sector debt, whether the intersection of the regression line with the axis of ordinates (free term) is equal to zero.

Table 3. The size of the *general government* sector debt of EU Member States in the years 2007-2013 (in billions of euros)

The formulated hypothesis concerning the size of the *general government* sector debt in the Member States of the European Union, according to which lack of State aid to enterprises in difficulty will reduce the *general government* sector debt to zero, must be rejected. Outside the United Kingdom, the test for individual Member States exceeds a critical value $t_{\alpha/2} = \pm 2.5706$ for $\alpha = 0.05$ and $n - 2 = 5$ degrees of freedom. The probability of making type I error is smaller than the accepted significance level of 0.05, and thus it is very unlikely that the wrong conclusion will be drawn that not granting State aid by a Member State for rescuing and restructuring undertakings cannot lead to a total decrease of the *general government* debt in the European Union. With a probability of 0.95 it can be concluded that in the absence of State aid for rescuing and restructuring in the EU the *general government* sector debt of all 28 Member States should adopt a value between (€ 4922.26 billion, € 18908.46 billion). In the case of Poland this range would form: (€ 154.14 billion, € 244.54 billion). The interpretation in relation to the UK is noteworthy at first glance, where the cessation of granting aid to enterprises in difficulty could lead not so much to total reduction of public debt, but also to developing substantial budget surpluses. However, this is due to a large type I error value (p-value), which is much

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

higher than the reference threshold of 0.05, which prevents the rejection of the null hypothesis in favor of the alternative hypothesis.

The most essential statistical test in a simple regression analysis is a test of whether the regression coefficient equals zero. If in a particular case a conclusion can be drawn that the slope coefficient of the true regression line in the population equals zero, it will mean that between expenditures on State aid to enterprises in difficulty and the size of the *general government* sector debt there is no linear relationship, or expenditures on aid and the size of the *general government* sector debt are not linearly dependent. Therefore, it is needed to test the occurrence of linear relationship between expenditures on State aid for rescuing and restructuring undertakings in difficulty in the Member States and the size of the *general government* sector debt. The statistics on this test are shown in table 5. Based on the calculations, it should be stated that the statistical basis for the recognition of the occurrence of a linear relationship between expenditures on State aid and the size of the *general government* sector debt do not exist both in the case of the individual Member States, as well as at the level of the European Union (EU- 28). In other words, on the basis of the t-test value and the value of the probability of making II kind error the hypothesis can be tested which concerns the lack of stochastic relation between State aid to enterprises in difficulty and the amount of the *general government* sector debt providing such aid EU Member States, in such a way that it is not possible to reject the hypothesis zero for the alternative hypothesis, which means lack of stochastic dependence between the studied variables.

The lack of the linear relationship between expenditures on State aid for rescuing and restructuring undertakings in difficulty in the EU Member States and the size of the *general government* sector debt is also confirmed by the F test parameters, that is the value of F-test and the probability of type I error, when hypothesis is verified which regards the lack of impact of expenditures on State aid aimed at rescuing and restructuring on the size of the *general government* sector debt (irrelevance of expenditures on State aid in the regression model). For all the countries indicated F-test values are lower than the critical value of 6.608, and the probability of making type I error is higher than 0.05. The calculations in this regard are presented in table 6.

Analyzing the correlation coefficient, it should be noted that they are contained within the range of (0.01832; 0.734479). However, even in the case of countries which are characterized by the highest correlation between the amount of aid to enterprises in difficulty and the level of their

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

debt in relation to the *general government* sector (Slovenia, Romania, Bulgaria, Belgium), there can be no satisfactory adjustment of the regression line to the empirical data. The determination coefficients for these countries equal 0.539459; 0.503136; 0.47616; 0.456829. This means that the variation in the size of the *general government* sector debt of Slovenia, Romania, Bulgaria and Belgium was explained in approx. 50% by the variability in the expenditures of these countries on State aid for rescuing and restructuring undertakings in difficulty. The remaining approx. 50% is the effect of random and non-random factors (other non-aid variables, inaccuracy of adjusting straight line to the empirical data etc.). If the determination coefficient takes less than 0.5, the regression explains only less than 50% of the variation of the size of the *general government* sector debt and predictions based on such a regression model may be unsuccessful because the regression model explains then very little.

Conclusions

Conducted regression analysis showed that between expenditures of the EU Member States on aid for rescuing and restructuring undertakings and the condition of the public finances of these countries there is no substantial statistical relationship. Granting aid by Member States to enterprises in difficulty does not affect the size of the *general government* sector debt of these countries. The question that now arises is whether: is the (potential) lack of impact of State aid for rescuing and restructuring undertakings on the size of the *general government* sector debt the sufficient justification for its granting? It should be noticed that the principle of compatibility of State aid to the mechanisms of the Single European Market is to provide State aid for the "positive" purposes that is in order to encourage beneficiaries of this aid to the activities that are considered desirable from the point of view of common European interest. Taking into account that the purpose of the "common interest" may be of a social or economic nature, State aid granted by Member States is to be directed at targets, such as environmental protection, job creation, investment in research and innovation, or the development of small and medium-sized enterprises. State aid in accordance with the provisions of the Treaty is to encourage activities to a greater extent than the market would be willing to provide. Therefore what is the purpose of the State aid for rescuing and restructuring enterprises in difficulty? The aim of this seems not to support a particular activity, but to support the activities "as such". State aid for rescuing and restructuring undertakings in

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

difficulty, that is, enterprises often already standing on the brink of bankruptcy, is concerned to protect existing business activities from the disappearance, which seems to be inevitable without State intervention. The conclusion can be drawn that such aid is not so to encourage specific actions as to prevent the liquidation of its business activities, which would be a natural consequence of the action of the market mechanism. This is especially seen in the case when the State aid is not for the actual restructuring of the enterprise, but it is spent to pay debts or maintain overcapacity. Such activities are often the result of the resistance of the public authorities from the introduction of the necessary, but difficult from the social perspective, changes. But this phenomenon can lead to favoring specific social groups, which can be seen in the case of big enterprises threatened with bankruptcy which operate in sensitive sectors, e.g. the mining industry, shipbuilding, rail, automotive. And does this kind of aid only delay necessary from economical point of view, but unacceptable for political reasons, certain restructuring actions, in particular the reduction of employment? The answer to this question is essential primarily from the perspective of the notification procedure under which the European Commission assesses the compatibility with the internal market of the plans of aid notified by the Member States. As far as in the case of any other State aid the notification procedures which are to determine the admissibility of aid occur between the authorities of the Member State and the European Commission whereas the beneficiary is not formally a party to these proceedings, in the case of aid for rescuing and restructuring, the role of the beneficiary is principally important. In this case the beneficiary, which is often enterprise standing at the brink of bankruptcy, must develop a restructuring plan, and then implement it and consistently realize. Member State should have in this regard extra responsibility that comes from the fact that when reporting to the European Commission a restructuring plan, the Member State confirms the legitimacy and rationality of the destination of public funds for the project, thereby confirming its credibility.

Taking this into consideration the most important question arises. Does the State aid "to prevent the bankruptcy of undertakings" follow the condition of art. 107 par. 2 point c of TFEU? It is after all based on this provision of the Treaty, which constitutes the sectoral and regional aid, such aid is considered acceptable and compatible with the internal market (CFI, T-17/03, para 43). Is regulated by this provision conditional exclusion for providing by Member States public aid in fact the basis for the promotion of the least efficient enterprises that cope the worst with competition on the

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

free market and that in the absence of State aid would have to fall and thus give its share in the market to competitors generating lower costs or offering more attractive products? Action of Member States in connection with the effects of the recent financial crisis has shown that State aid for rescuing and restructuring enterprises in difficulty follows more the premise of art. 107 par. 2 point b of TFEU, according to which the anti-crisis aid may be granted. Anti-crisis aid is aid to remedy a serious disturbance in the economy of a Member State. Such aid must be the action taken in response to a crisis situation concerning the whole economy of the country (CFI, T-132/96 and T-143/96, para 167; ECJ, C-57/00 P and C-61/00 P, para 97). Therefore, these serious disturbances in the economy must be of a general nature and may not apply to only one region or one sector (ECJ, C-301/96, para 106). The financial crisis showed, however, that anti-crisis aid will also be admissible in the situation when it will be one sector of the economy, but considered through the prism of several Member States. In this context, State aid may be reasoned by significant decrease in employment, production or investment or threat to the existence of strategic companies. When we go back in time and look at the actions taken by the Member States in connection with the oil crisis in the 70s of the twentieth century, which have provided State aid in the steel industry practically without specifying its purpose – first to support the expansion of the sector, and then to prevent the collapse of enterprises - a proposal to declare State aid for rescuing and restructuring undertakings in difficulty as anti-crisis aid seems to be the most reasonable. The financial crisis of the first decade of the twenty-first century, such as the oil crisis of the 70s of the twentieth century, showed that State aid for rescuing and restructuring enterprises in difficulty will always be regarded as acceptable, when a group of entities (individuals, enterprises) interested in obtaining support is determined and focused while the cost of such support are paid by all taxpayers (the whole society), so the dispersed and less interested in the cost of such support group.

Innovation in Contemporary Economies

JEL Classification: *H53; O12; O32; O38*

Keywords: *innovation; knowledge; market economies; the state*

Abstract: The hereby article discusses the issues related to the existing or required support given by the State to enterprises in order to provide them conditions to innovate. Neoclassical economy puts an emphasis to the price mechanism as a decision making effective tool, but enterprises meet many barriers in creating and introducing innovation, like high cost, high risk or lack of demand for innovation. These phenomena tend to inhibit innovation of enterprises. This means that market is not an efficient mechanism for innovation activity of enterprises, and its imperfections provoke State's intervention. The goal of the article is to shape the objectives of State's impact on decisions of innovative enterprises. Research method is the critical literature review and public data on State's support on business R&D analysis. The research results show State's support for both – incremental and radical innovation, which proves that innovative activity of enterprises is far from being a spontaneous, market-based process.

Introduction

Contemporary economies development is strongly related to innovation. Innovations which are understood as „something new proven to be useful” cause the productivity-, value added- and – economic growth. The ultimate performers of innovation are enterprises. And according to Schumpeter – innovation is an autonomous feature of entrepreneur, who looks for new

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

solutions and introduces them to the market. And his most important goal is to maximize the profit. However innovation activity (especially in the field of disruptive innovations) is an activity that involves high cost, risk and uncertainty. Profits constituting the reward and the basic motivation for entrepreneur in innovative activity are highly uncertain and deferred. So the entrepreneur does not necessarily find innovative activity attractive. The question arises whether decisions on introducing innovative activity in enterprises are independent business decisions. If entrepreneur avoids high risk and uncertainty, what makes him to be innovative? The huge role plays the State. Its actions are of twofold: first – it reduces the “market imperfections” which makes innovative activity in enterprises possible. Second – the State creates markets and enables innovation diffusion. The goal of the article is to identify the tools thanks to which the State influences the innovative decision of enterprises in case of both: sustained and disruptive innovations.

Methodology of the research

The hereby article is an attempt to specify tools the State uses in purpose of stimulating the innovative behavior of firms. First the importance of innovation for economy has been described. There have been shown growth theories for which innovations (as a technological change) are the important pro-growth factor. The possible State’s actions in promoting technology-driven growth have been underlined. Then the innovations have been classified. Four innovation types have been listed with respect to two criteria: level of financial involvement and risk (profit). In the next paragraph the twofold attitude of entrepreneur to innovative activity has been taken into account (as a result of his opportunism) – autonomous (spontaneous) innovator, and “conditional” innovator. The first entrepreneur type is “Schumpeterian-like”, the other – “State-dependent”. Innovative activity of enterprises is a high-cost, high-risk activity, therefore the State – as a stimulus, plays a huge role here. There have been specified tools by which the State influences firms’ decisions, the tools have been matched with each innovation types. Therefore the two kinds of tools have been listed – classic and institutional. The R&D expenditures as the main category of classic tools has been considered.

In purpose of achieving the objectives of the hereby article the critical analysis of literature has been made, in territorial, theoretical and methodological contexts.

Innovation landscape

There have been said many words about innovation so far. As Oslo Manual (OSLO, 2005) says, innovation, as an outcome of creative application of knowledge, is seen to play a central role in the knowledge-based economies. It gives the knowledge a crucial role in economic processes and for this reason the nations that develop and manage effectively their knowledge assets perform better. And innovation – as a new product, process or method, freshly introduced to the market – is an outcome of relevant knowledge application. Its role is to bring wealth and social welfare (Vaitheeswaran, 2007), it is an inherent feature of entrepreneurship.

Entrepreneurship and entrepreneurial innovations constitute the basis for the first theory explaining the activities that lead to economic growth in capitalist economies. The author of that theory is Schumpeter (Schumpeter, 1960). His theory centers around entrepreneurial innovations and their role as the key driver of economic growth. Schumpeter argues that competition among market participants leads to a desire to seek out new ways to improve technology, new ways to do business and other types of advantages that would increase profit margins and directly impact the entrepreneur's standard of living. Schumpeter identified innovation as the critical dimension of economic change. He argued that economic change revolves around innovation, entrepreneurial activities, and market power. Schumpeter gives the entrepreneurial power of enterprises the leading role in creating innovation

Subsequent economic theories trying to explain the interplay between innovation and economic growth were Abramowitz (1956) and Sollow (1956) who showed that the economic growth is rather a result of “unexpected residual” reflecting the productivity growth rather than the quantity of production factors. But it was Robert Sollow who modeled the growth through production function, where output is a function of quantity of physical capital and human labor- *ceteris paribus*. The technological change responsible for innovation, was performed as exogenous to the production factors (Mazzucato, 2014, Woźniak, 2008, s. 189). As the technology became a more vital part of innovation and – growth landscape, the economists had to reconsider its place in the growth models. This gave rise to the “endogenous” or the “new growth” theory. This theory states that it is the technology that gives the endogenous outcome of an R&D investment function as well as investment in human capital formation (Grossman,

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

Helpman 1991). It is noteworthy that in the new growth theory new ideas were treated as endogenous to the enterprise, not to the institutional organization that transforms ideas into products. The relation between technological change and growth indirectly led policymakers to focus on the importance of investment in technology and human capital to foster growth (Mason, Bishop, Robinson 2009). The consequence of that is the emergence of innovation-led growth policies, that support the knowledge economy. Policy indicators like R&D spending and patent success became the evidence of the market value of firms and their innovation performance. But the State with its policies became a vital part of the innovation landscape.

The 'Evolutionary Theory of Economic Change' (Nelson, Winter 1982) was built in opposition to the endogenous or exogenous growth theories. The theory was built on the basis of Schumpeterian approach to innovation. In perspective of this attitude innovation is firm specific and highly uncertain.

The mix of Schumpeterian and 'evolutionary' approach to studying firm's pro-innovation behavior has led to the 'systems of innovation' policy, where the most important thing is to understand the way in which firms are set in a system of sectoral, regional or national levels. In this view not the quantity of R&D is important but the way it is distributed throughout the economy. And here's the place for State's dominance – it is the State that influences the distribution. The definition of systems of innovation describes relations of economic actors: "...networks of institutions in public and private sectors whose activities and interactions initiate, import, modify and diffuse new technologies" (Freeman, 1995) , or "...the elements and relationships which interact in the production, diffusion and use of economically useful knowledge" (Lundvall, 1992).

The importance of innovation for the economy's performance is unquestioned. Schumpeter asserted that innovation is a result of autonomous entrepreneurial decisions of entrepreneurs. Further growth theories found innovative activity of the firms susceptible to State's action in form of innovation support policies. The question is – who is the innovator? Is it still an autonomous enterprise or not? Are profit prospects that significant that enterprises innovate (or auto-innovate)? Or is it State's policy that introduces innovation to enterprises (by lowering risk and costs)?

Types of innovation

The crucial issue at this moment is to understand the idea of innovation. The dominant part of each innovation definition is the word “new”. So innovation is defined as a new solution, new product, new process. Its novelty is the most important part of the definition. Innovation is a solution introduced to the market. Innovation without the market success is only an invention.

But how new the innovations are? The definitions of innovation show a wide range of possible examples of innovative solutions. From small-step improvements to great, disruptive projects. But are the enterprises equally willing to create incremental and radical innovations? Where is the difference between these definitions.

Incremental innovation can be understood as series of small improvements to an existing product or product line that usually helps maintain or improve its competitive position over time. Radical innovation is concerned with exploration of new technology, it is fundamentally different from incremental innovation that is concerned with exploitation of existing technology. "Radical innovation is a product, process, or service with either unprecedented performance features or familiar features that offer potential for significant improvements in performance and cost"(Leifer et al., 2000). It creates such a dramatic change in processes, products, or services that they transform existing markets or industries, or create new ones. The differences between incremental and radical innovation are shown in **Table 1**.

Table 1. Radical vs. Incremental innovation

Radical innovation	Incremental innovation
Explores new technology	Exploits existing technology
High uncertainty	Low uncertainty
Focuses on products, processes or services with unprecedented performance features	Focuses on cost or feature improvements in existing processes, products or services
Creates a dramatic change that transform existing markets or industries, or creates new ones	Improves competitiveness within current markets or industries

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

In 1997 Clayton M. Christensen in his seminal work suggested different view on the innovation. He's also identified two kinds of innovation: disruptive and sustaining one (Christensen, 2010).

The first characteristic of a disruptive innovation is that it initially provides inferior performance (as measured by the prevailing industry metrics) to existing products available. As a result, it is usually not of much interest to existing users or customers. The second characteristic of a disruptive innovation is that it is adopted by a market that is currently underserved or not served at all. In other words, it serves a market segment that did not exist before. Since disruptive innovations are usually not of interest to a company's existing customers, market leaders are rarely the source of disruptive innovations.

As opposed to disruptive innovation is a sustaining one. Sustaining innovation is one that perpetuates the current dimensions of performance – for example Intel developing faster and faster chip speed. In contrast to disruptive innovation, a sustaining innovation does not create new markets or value networks but rather only evolves existing ones with better value, allowing the firms within to compete against each other's sustaining improvements. Sustaining innovations may be either "discontinuous" (Christensen describes as "revolutionary" innovations as "discontinuous" "sustaining innovation" i.e. "transformational" or "revolutionary") or "continuous" (i.e. "evolutionary") (Christensen, 2010, p. 21-22).

Radical and disruptive innovation differ. Radical innovation almost always seems to mean an order of magnitude improvement in performance or a significant shift from existing performance or solving a complex problem that existing products don't solve. This means more sophisticated technology, based on pushing the boundaries of knowledge (like biopharmaceutical drugs – completely different technology addressed to medical problems that could not be solved satisfactorily by existing drugs).

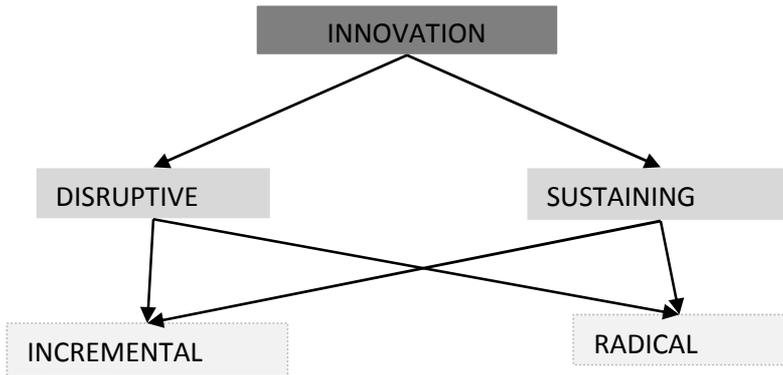

Disruptive innovations don't need to be based on radical technological innovations of this nature (microfinance, for example, did not involve radically new technology). But some disruptive innovations can be radical as well.

Radical innovations would rarely be classified as disruptive because, as we have seen, they are often aimed at driving the performance frontier rather than serving under-served or unserved markets.

Undoubtedly these two classifications of innovation refer to different distinctive features. Incremental and radical innovation are innovation types distinguished due to the creation method. Disruptive and sustaining

innovation are more about consequences that entrepreneurs have to bear due to market introduction of a new product or process. This means that from entrepreneur's point of view there are two kinds of innovation: disruptive and sustained. And these innovation types have two features each: radical or incremental.

Figure 1. Innovation types and features

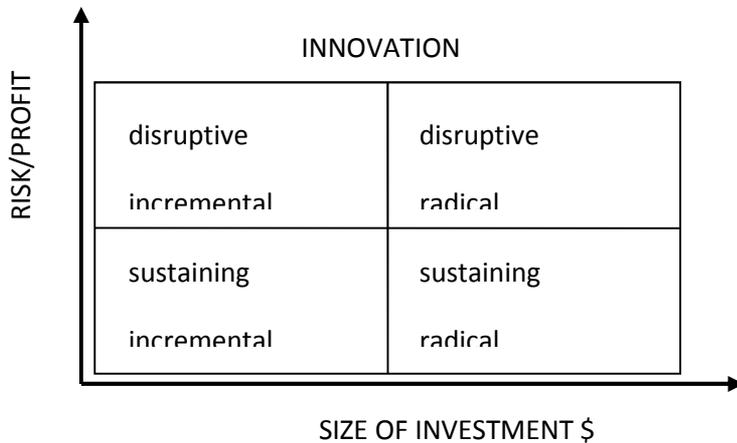

Source: own work.

The crucial determinant of entrepreneur's engagement in innovative activity is the level of risk. And the risk (uncertainty) level is correlated to the height of investment done (the higher uncertainty level the more money is being invested). The motivation for high-risk, high-cost investment is a possibility of obtaining a profit that is higher than in any alternative activity.

The level of risk is the determinant of autonomous innovative activity of enterprises. With increased risk the propensity to innovate autonomously decreases. Unlike Schumpeter claimed, enterprises do not fancy risk much enough to invest in areas where returns are highly uncertain. This puts disruptive radical innovations in the position of the matrix (see **Figure 2**) where the level of the risk and money necessary to invest discourage firms from their entrepreneurial activity. If the level of autonomous firm's involvement in innovative activity can be understood as the money that enterprise is willing to invest – the term "incremental" will determine the autonomous innovation activity of enterprises. High profits from disruptive incremental innovations can be understood as a bonus here.

Figure 2. The innovation matrix

Source: own work

High level of investment is the barrier that stops many firms from innovative activity. Radical sustaining innovations are high cost/low risk ones, and they result with smaller profits than disruptive radical ones, which are top risk and top cost ones. Undoubtedly they have a potential of high profits, but at high cost that excludes enterprises from this kind of activity. This means that enterprises behave in a Schumpeterian way in a limited extend.

Inclination to innovation

According to the types of innovation selected in the previous paragraph one can find that the criterion of firm's involvement in innovative activity is first – the cost, and second – the risk. This means that the autonomous innovative activity of firm refers mainly to the incremental innovations. The sustaining incremental and the disruptive incremental innovations are both the low cost ones. And more often the result is sustaining than disruptive. The relation between incremental innovation and growth is inadequate. As Tucker in his seminal work says: “Because much of the innovation taking place today is incremental, so is its impact on growth. Little ventured, little gained” (Tucker, 2008) . It means that entrepreneurial behavior of firms seeking innovation does not bring the growth. And the improvements – important to firm's production process because of the

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

productivity increase and firm's economic performance, do not cause the upswing of economy's competitiveness.

On the opposite corner of the innovation matrix there is disruptive-radical innovation. If succeed – guarantees high profits and new market emergence. It is a high-risk and high-cost activity that majority of enterprises will not choose. It is concentrated on new knowledge creation (more like basic, than applied or experimental research). Moreover – disruptive radical innovation do not only mean “high cost”. They also mean “new product” with no existing market. So the profits from this kind of activity are possible to achieve in a more distant future than an enterprise is willing to wait for. But disruptive radical innovations have a positive impact on economy's performance. They are more likely to create growth and increase competitiveness than incremental ones. So are radical-sustaining innovations. They can create new markets, they do not break the business cycle but they create new products. They are developing new technologies.

Enterprises do not accept the high-risk innovation activity, but such an activity can cause many benefits to economy. The catalyst of high-risk innovation activity is the State. The State's activity is twofold. The classical attitude to the role of the State in the economy concerns “market failure” approach. State's role is to fix the “market failures”, which are unexpected (and therefore not included in the costs) external effects of economic activity of market players like, for example: pollution (a negative externality, not included in firm's costs), etc. Standard economic theory justifies State's intervention when social return on investment is higher than private return, which makes it unlikely that private business will invest (Mazzucato, 2014). The modern attitude to State's role on this field is more complex. The State's role is not only to “de-risk” private sector decisions. It's role is to solve main socioeconomic questions like ageing, hunger, diseases, climate change, etc. Rather than active correction of ‘market failures’ its role is to shape and create the markets. The most adequate here are the findings of Karl Polanyi (1944), who emphasized how the capitalist ‘market’ has from the start been heavily shaped by State's actions. In innovation, the State not only ‘crowds-in’ business investment but also ‘dynamizes it in’ – creating the vision, the mission and the plan.

Tools to promote innovation

In general, State's impact on innovation in enterprises is at least two-fold. First – State can provide a direct or indirect support. This is a well-known kind of support used as a part of country's industrial policy. The support given to enterprises may take the form of direct (e.g. subsidies, grants, loans etc.) or indirect (fiscal policy instruments) financing. It can also have a form of institutional support (like DARPA or SBIR for innovation in USA). Second – knowledge-based economies are strongly dependent on new knowledge. Therefore State's role is also to create society's creativity in order to reap benefits from it.

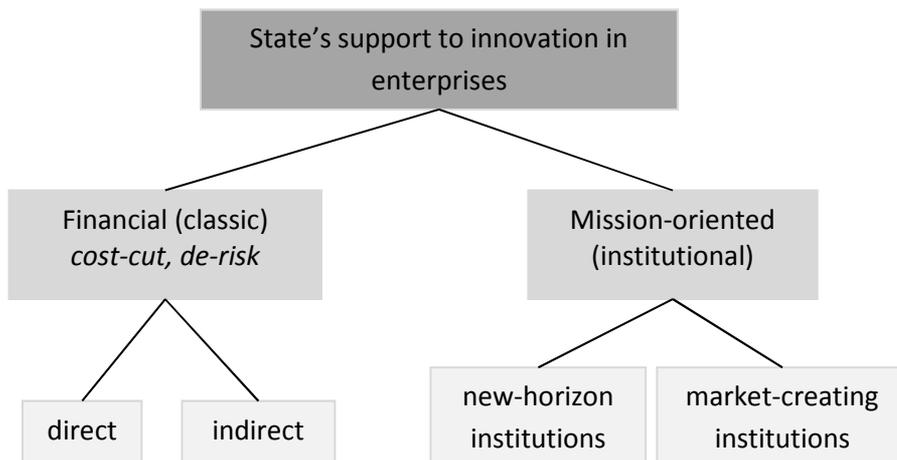

It is noteworthy that State's support to enterprises in form of financing R&D expenditures is dedicated more to incremental innovation than to radical ones. The high risk and uncertainty of the innovation process are the main reasons for which profit-maximizing companies would invest less in basic and more in applied research (D from R&D). The greater and more immediate returns from the latter are a good explanation to these. Investment in basic research is a typical example of fixing 'market failure' where the market alone would not produce enough basic research, so the government must step in. Therefore enterprises mainly get involved in the development, which is a more predictable activity than research (especially basic research). Innovations that arise in this way are mainly improvements and developments of existing products or processes. Radical innovations strongly rely on new knowledge, that is created mainly in form of basic research. As the data show (OECD 2013, p.102, OECD 2014, p. 194) most basic research is performed in universities and in public research organizations. The mission-oriented, highly risky and unsecure, but potentially extremely profitable projects are based upon basic research. For the US economy, for example, government spending on R&D makes up only 26 per cent of total R&D, with the private sector making up 67 per cent, the proportion is much higher when basic research is considered in isolation. Indeed public spending accounts for 57 per cent of basic research in the USA, with the private sector taking on only 18 per cent (Mazucatto, 2014). So the State's support to this kind of research institutions influences new knowledge creation and therefore impacts both forms of radical innovation creation.

The State's support to innovation does not only mean reduction of risk and cost, especially in case of disruptive innovations. Disruptive innovations constitute the supply of innovations that are addressed to an unknown

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

market or – such a market does not exist yet. Therefore States’ support must reach far beyond financing. The interplay between demand and supply is needed here to provide a market for innovation. The problem has been widely discussed in literature (Etzkowitz, 2008).

Figure 3. State’s support to innovation in enterprises

Source: own work

As presented in Figure 3 State’s support to innovation in enterprises is twofold. Financial support to innovation creation considers mainly financing of enterprises R&D activity – directly or indirectly (see Table 2).

Table 2. Major public instruments for financing business R&D and innovation

Financing instruments		Key features	Some country examples
Direct public funding	<i>Grants, subsidies</i>	Most common funding instruments. Used as seed funding for start-ups and innovative SMEs. Granted on a competitive basis and in some cases, on the basis of private co-funding. No repayment is usually required. Supply-side, discretionary instruments.	ANR subsidies (Argentina), Central Innovation Programme for SMEs(Germany), R&D Fund (Israel), SmallBusiness Innovation Research (SBIR)Program (USA)
	<i>Debt financing</i> <i>Credit loans</i>	Government subsidised loans. Require sorts of collateral or guarantee. Obligation of repayment as debt. The investor/lender does not receive an equity stake.	Novallia (Belgium), High-Tech Gründerfonds (Germany), Public Investment Bank (France), Microfinance Ireland, Slovene Enterprise Fund, British Business Bank (Great Britain)

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

		<i>Repayable grants/ advances</i>	Repayment required, partial or total, sometimes in the form of royalties. Could be granted on the basis of private co-funding.	Repayable Grants for Start-Ups (New Zealand)	
		<i>Loans guarantees and risk-sharing mechanism</i>	Used widely as important tools to ease financial constraints for SMEs and start-ups. In the case of individual assessment of loans, can signal ex ante the creditworthiness of the firm to the bank. Often combined with the provision of complementary services (e.g. information, assistance, training)..	Small Business Financing Program (Canada), Mutual guarantee schemes (Confidi) (Italy), 7 Loan Program (USA), R&I Loans Services (European Commission)	
	<i>Debt/equity financing</i>	<i>Non-bank debt/equity funding</i>	New funding channels. Innovative lending platforms and non-bank debt or equity funds.	Business Finance Partnership (Great Britain)	
		<i>Mezzanine funding</i>	Combination of several financing instruments of varying degrees of risk and return that incorporate elements of debt and equity in a single investment vehicle. Used at later stage of firms' development. More suitable for SMEs with a strong cash position and a moderate growth profile.	Guarantees for Mezzanine Investments (Austria), PROGRESS Programme (Czech Rep.), Industrifonden and Fouriertransform (Sweden), Small Business Investment Company (USA)	
	<i>Equity financing</i>	<i>VC funds and funds of funds</i>	Funds provided by institutional investors (banks, pensions funds, etc.) to be invested in firms at early to expansion stages. Tends to increasingly invest at later -less risky- stage. Referred as patient capital, due to lengthy time span for exiting (10-12 years). The investor receives an equity stake.	Seed Fund Vera (Finland), France Investment 2020, Yozma Fund (Israel), Scottish Co-investment Fund (Great Britain)	
		<i>Business angels</i>	Provide financing, expertise, mentoring and network facilities. Tends to invest in the form of groups and networks. Financing at start-up and early stage.	Seraphim Fund (Great Britain), Tech Coast Angels and Common ANGELS (USA)	
		<i>Innovation vouchers</i>	Small lines of credit provided to SMEs to purchase services from public knowledge providers with a view to introducing innovations in their business operations.	Innovation vouchers (Austria, Chile, China, Denmark, etc.)	
	Indirect public funding	<i>Tax incentives</i>	<i>Tax incentives on CIT</i>	Used in most countries. Broad range of tax arrangements on corporate income tax, including tax incentives on R&D expenditure and, less frequently, tax incentives on IP-related gains. Indirect, non-discriminatory.	SR&ED tax credit (Canada), R&D Tax Credit (France), exemption on payroll withholding tax (Netherlands), patent box (Great Britain)
			<i>Tax incentives on PIT</i>	Available in many countries. The State's mission-oriented support for business innovation can be characterized as institutional support, because the State – through establishing the institutions affects both – firms' propensity to involve in risky and costly activity and creates the conditions for innovation to diffuse. They are both important to disruptive innovations. There are numerous examples of State's activity in this field. For example public procurement for R&D and innovation. It is an instrument that creates a demand for technologies or services that do not exist, or, targets the purchase of R&D services (pre-commercial procurement of R&D). It also provides early-stage financial support to high-risk innovative technology-based small firms with commercial promise. The country example is Small Business Innovation Research (SBIR) Program (USA) and SBIR-type of programs (UK). Another example can be technology consulting services and extension programs that expand the diffusion and adoption of already existing technology, and contribute to increase the absorptive capacity of targeted firms (especially SMEs). Provide information, technical assistance, consulting and training, etc.

A great example of institution that gave rise to new disruptive innovations is DARPA. It was set up to give the USA technological superiority in different sectors, mainly those related to technology. Its budget is more than 3 billion USD per year, 240 staff. Going beyond simply funding research DARPA funded the formation of computer science departments, provided start-up firms with early research support, contributed to semiconductor research and support to human-computer interface research, oversaw the early stages of Internet. DARPA provided both – supply and demand for innovation (Mazucatto, 2014). The next example is SBIR – a consortium between Small Business Administration and different government agencies like Department of Defense, Department of Energy and Environmental Protection Agency. The Small Business Innovation Research programme required government agencies with large research budgets to designate a fraction (ca. 1,25%) of their research funding to support small, independent firms. As a result many highly innovative start-ups were supported. Literature shows other examples of successful institutional support, like Orphan Drug Act (ODA) supporting biotechnology or, National Nanotech Initiative (Mazucatto, 2014).

One can notice that support given to disruptive radical or disruptive incremental innovations is not only about financing. Even more important issue here is creating a markets for innovation or “picking winners” –

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

which means targeting a new growth areas (as a result of industry-university-enterprise interplay).

Conclusions

Innovation in market economy comes from enterprises. Anyway enterprises are innovation producers. But innovative activity comes not only from enterprises opportunism. Schumpeter claimed that entrepreneurship means innovation. In modern market economies innovation is strongly addicted to new knowledge creation which often means – it's risky and costly. And entrepreneurs avoid high risk and cost. But the innovation gives growth and wealth, increases competitiveness of economies. There are numerous tools supporting innovation in business, but the most growth-giving innovations are disruptive innovations but their characteristics exclude enterprises as innovative agents. The State, as a main beneficiary of innovation (growth) takes the control on promoting and supporting innovation with help of numerous supporting tools.

The history of breakthrough innovations shows, that State's role in promoting innovation in business, goes far beyond financial tools. The State finances the most risky research – basic and applied, but also can be – and usually is – the source of the most radical disruptive innovations. The State's role is not only to “fix markets” but also to create them.

Moreover, State – thanks to its institutions (laboratories, agencies, Acts) has a potential to accelerate the knowledge diffusion. This means, that the State is a main player of the innovation system, so its role is not limited to the country level, neither to long-term subsidies for specific sorts of activity. The State, in order to create markets and introduce technological progress, use regulatory tools, orders, public procurement. It means that the State is the catalyst for technology change.

**On the Use of Panel Stationarity Tests
in Convergence Analysis: Empirical Evidence
for the EU Countries***

JEL Classification: *C22; C23; O47; O52*

Keywords: *economic growth; convergence; catching up; stationarity; ADF test*

Abstract: The study examines the concept of stochastic convergence in the EU28 countries over the 1994-2013 period. The convergence of individual countries' GDP per capita toward the EU28 average per capita income level and the pair-wise convergence between the GDP of individual countries both are analyzed. Additionally, we introduce our own concept of conditional stochastic convergence which is based on adjusted GDP per capita series in order to account for the impact of other growth factors on GDP. The analysis is based on time series techniques. To assess stationarity, ADF tests are used. The study shows that the process of stochastic convergence in the EU countries is not so widespread as the cross-sectional studies on β or σ convergence indicate. Even if we extend the analysis to examine conditional stochastic convergence, the number of converging economies or pairs of countries rises but not as much as it could be expected from the cross-sectional studies.

* The research project has been financed by the National Science Centre in Poland (decision number DEC-2012/07/B/HS4/00367).

Introduction

Ever since the Sala-i-Martin's and Barro's and Mankiw et al.'s well recognized studies (see e.g. Barro & Sala-i-Martin, 1990, 2003; Mankiw et al., 1992), the issue of income-level convergence has gained huge popularity in the literature. The two most common concepts of convergence were proposed: β convergence (when less developed countries grow faster than more developed ones) and σ convergence (when income differences between economies decrease over time). A number of methods have been developed which enable for empirical verification whether the process of convergence actually is taking place, starting with the cross-section based Barro regression as the most popular technique that enables for the verification of the β convergence hypothesis.

However, parallel to the classical definitions and methods of analysis, the concept of stochastic convergence has been theoretically and empirically developed in the literature. With the gradual development of panel data based stationarity tests, the range of tools available for empirical analysis has rapidly increased and there currently exist numerous tools that allow to verify empirically the existence of so called stochastic convergence. Its idea, dating from the early nineties and described fully in such papers as Bernard & Durlauf (1995), is to define convergence on the basis of time series rather than – as in the case of the most popular β convergence – cross section, though recently both concepts have been seriously developed due to popularity of panel data studies. Contrary to the β -convergence-type thinking in which it is the current situation and the recent influence of the lagged GDP on current growth, in the case of stochastic convergence it is the expected value of future differences between the GDP levels in different countries that are taken into account. In the case when there is stochastic convergence, the basic concept is to expect the difference between the level of development to be zero in the infinite time horizon.

All the concepts of convergence are interrelated. However, they should be tested separately and treated as complementary rather than substitutive. Since they require different estimation methods, the results need not be the same. For example, as Bernard & Durlauf (1996) indicate, time series tests are based on a stricter notion of convergence than the cross-section tests; hence, under certain assumptions, the cross-section tests can spuriously reject a no-convergence hypothesis while time-series tests do not.

Our analysis covers the 28 European Union countries (EU28) and the 1994-2013 period. We examine the stochastic convergence of the individu-

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

al countries toward the EU28 average per capita GDP level as well as between the pairs of the individual countries (by examining 378 pairs).

A new element of our analysis is the extension of the classical concept of stochastic convergence. The stochastic convergence, implying that GDP differences against the group average or between the individual countries diminish over time, is called the absolute stochastic convergence. However, as in the case of the β convergence, we extend this approach for conditional convergence because there are many factors of economic growth and it is difficult to assume that all the countries tend to the same steady state. Namely, we adjust the GDP time series by eliminating the impact of selected economic growth determinants to account for the fact that the countries are not homogenous in terms of economic growth factors. The analysis of stochastic convergence on the adjusted-GDP time series is the core of the concept of stochastic conditional convergence. ADF tests are used to test for stationarity of the series of differences between the GDP of a considered country and mean GDP of the considered group of countries (as in Bernard & Durlauf, 1995), however, ADF tests are also used in the Pesaran's (2007) procedure of testing stationarity of the series of GDP gaps in each possible pair of countries from the considered group. The GDP series might though not converge due to serious diverging trends caused by different values of GDP growth factors in different countries. That is why we follow by checking the existence of conditional stochastic convergence by first estimating a panel-data-based β convergence equation. We use the estimates of parameters on the growth factors to eliminate their influence from the GDP growths of different countries and follow by reconstructing the GDP level series, applying the *ceteris paribus* rule with regard to the considered growth factors. We then repeat the above described procedures of Bernard & Durlauf and Pesaran with the series from which the influence of the growth factors has been eliminated.

There is a lot of empirical studies on cross sectional β and σ convergence. Abreu et al. (2005) found an enormous number of 1650 empirical articles on convergence. Matkowski et al. (2013) present a wide review of empirical studies on convergence for the EU countries. The studies in which stochastic convergence is analyzed appear less frequently in the literature, although they are by no means scarce.

For instance, Bernard & Durlauf (1995) reject the existence of stochastic convergence in the whole group of the 15 OECD countries over the 1900-1987 period, but find substantial evidence for common trends (smaller samples of European countries did not converged either). Pesaran (2007)

examines both the output and growth stochastic convergence among the world countries from 1951 to 2000 (the number of countries for some sub-periods exceeds 100) concluding that there is no output convergence and the findings of convergence clubs in the literature might be spurious, but there is significant evidence of growth convergence. Other studies in which stochastic convergence (in different operational form) with the use of time-series techniques was tested for various groups of countries include: Cuñado & Pérez de Gracia (2006) for African countries; Christopoulos & León-Ledesma (2008) for the OECD countries; Cunado (2011) for the OPEC countries; Evans & Kim (2011) for the Asian countries. Stochastic convergence was also examined in the regional context by: Kane (2001) for the U.S. regions; Lau (2010) for Chinese regions; and Le Pen (2011) for European regions. However, we have not seen in the literature the study in which the stochastic convergence for the whole EU28 group was examined in the way adopted here.

The paper is composed of four sections. The next section discusses the research methodology by presenting the concept of absolute and conditional stochastic convergence. The further section describes and discusses the results. The last section concludes.

Methodology of the research

Let $\ln GDP_{i,t}$ represent the logarithm of the GDP of country i in period (year) t . We can then state that countries i and j converge stochastically¹ if

$$\lim_{k \rightarrow \infty} (\ln GDP_{i,t+k} - \ln GDP_{j,t+k} | I_t) = 0, \quad (1)$$

where I_t represents the set of information available at time t , and the $\ln GDP_{i,t}$ throughout the paper is the natural logarithm of the i th country's GDP per capita (at purchasing power parity at constant US\$) in year t . The econometric way to see and test for the above is to notice that for the formula (1) to be fulfilled, a cointegrating vector $[1, -1]$ is required for the series $\ln GDP_{i,t}$ and $\ln GDP_{j,t}$. Suppose we are testing for convergence in

¹ This definition is quite strict – Bernard & Durlauf (1995), among others, also define a more liberal concept of common trend in bivariate or multivariate output, whose special case is the exact stochastic convergence. That requires replacing formula (1) with $\lim_{k \rightarrow \infty} (\ln GDP_{i,t+k} - \gamma \ln GDP_{j,t+k} | I_t) = 0$.

the bivariate case of countries i and j . That requires computing the gap series

$$dGDP_{ij,t} = \ln GDP_{i,t} - \ln GDP_{j,t} \quad (2)$$

and testing for the stationarity of the $dGDP_{ij,t}$ series.² Usually a variation of the ADF test would be used here, though Pesaran (2007) among others discusses also the KPSS-type tests as the power of ADF tests is questionable especially in the case of short series.

Should a group of – potentially – converging countries include more than two of them, two main options are available. Again following Bernard & Durlauf (1995) and most other research, one can test for convergence replacing the series of gaps between two countries output (2) with the series of gap between the $\ln GDP_{i,t}$ and its mean in a group of considered countries:

$$dGDP_{i,t} = \ln GDP_{i,t} - \overline{\ln GDP}_t, \quad (3)$$

while the definition of stochastic convergence (1) would now be replaced with

$$\lim_{k \rightarrow \infty} (\ln GDP_{i,t+k} - \overline{\ln GDP}_{t+k} | I_t) = 0. \quad (4)$$

Pesaran (2007), however, points out the weakness of such a procedure and suggests a modified approach for the multivariate case. Its core in a group of N countries is to check for stationarity of gap series defined as (2) for every possible pair of countries, that is for all the $N(N-1)/2$ non-redundant cases. With the support of simulation studies, Pesaran argues for the efficiency of such a procedure and points out that if we apply the ADF-type tests of stationarity and assume certain level of significance α , then if there is no convergence in the considered group, the rejection rate of the null hypothesis shall asymptotically tend to α .

In this paper we analyze the convergence of the group of the 28 EU countries. The annual series of data start in 1994 and finish in 2013. Both the convergence to mean (as in (4), $i=1, \dots, 28$) and pairwise convergence

² In the case of common trends instead of the strict stochastic convergence, the test of trend-stationarity would be used instead and the cointegrating vector would need to be $[1, -\gamma]$.

(as in (1), $i,j=1,\dots,28$) are analyzed. An ADF test is used with a single lag in each of the equations (we check that it is sufficient to eliminate the – in most cases slight – autocorrelation of $dGDP_{ij,t}$ and $dGDP_{i,t}$ respectively).

In the analyses of the β convergence it is common to consider two types of it: the absolute and the conditional convergence. We suggest a similar approach in the field of stochastic convergence. There is a possibility that the series of $\ln GDP$ of certain country would not be converging due to other than autonomous reasons. Namely: flow of physical as well as human capital and technical thought would make it converge if it were not for the values of certain growth factors. As an example, suppose that the government of the country does everything it could in order to convert it in an autarchy, which naturally limits also the flow of technical thought. Further suppose that the government consumption is excessively high. It might be that unless these two factors slowed down the convergence process, the country would be heading towards the rest of the considered group, but as the two above mentioned growth factors play a highly negative role, the convergence of the pure series of $\ln GDP$ would not be observed. In order to overcome this issue we propose analyzing the convergence of the series of adjusted $\ln GDP$. The proper correction that should be applied consists in eliminating the influence of the (non-homogeneous across countries) growth factors that distort the series. The procedure that we suggest is the following.

As the first step, we estimate a Barro-type model of GDP convergence as in Próchniak & Witkowski (2013). The functional form of the estimated model is

$$\Delta \ln GDP_{it} = \alpha_i + \beta_0 \ln GDP_{i,t-1} + x'_{it} \beta + \varepsilon_{it}, \quad (5)$$

where α_i is the individual effect of i -th country, β_0 is the β -convergence parameter, x_{it} is the vector of the growth factors while β is the vector that covers their influence on the GDP growth and finally ε_{it} represents the error term. The model itself is estimated as such while cross-sectional data are used, while a minor transformation is applied in the case of panel-data-based analysis as it is in this paper (Próchniak & Witkowski, 2014).

In this paper the convergence of the EU28 group is considered in the 1994-2013 period. We thus have a panel with annual observations and the Blundell and Bond's system GMM estimator is used (Blundell & Bond, 1998). Given the economic sense and data availability, the following variables are considered as economic growth determinants

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

- log of lagged GDP per capita (at purchasing power parity at constant US\$);
- investment (% of GDP) – *inv*;
- general government consumption expenditure (% of GDP) – *gov_cons*;
- openness rate ((exports + imports)/GDP) – *open*;
- current account balance (% of GDP) – *cab*;
- inflation (annual %) – *infl*;
- log of fertility rate (births per woman) – *fert*;
- population growth (annual %) – *pop_gr*;
- population ages 15–64 (% of total) – *pop_15_64*;
- log of life expectancy at birth (years) – *life*;
- log of population, total – *pop*.

The last two variables (*life* and *pop*) are further eliminated in the step-wise regression procedure and they are not included in the final model.

The aim of this study is not to explain fully the sources of economic growth. Instead, the aim is to include in the GDP growth regression the factors that from the theoretical and empirical point of view are the most important determinants of both the pace of economic growth and the steady-states to which the individual countries are tending. The choice of control variables is based on our earlier studies on β convergence and economic growth determinants. The set of variables includes typical and significant factors of economic growth, but of course not all the possible time series. The variables that represent population aspects – mainly responsible for human capital – (*fert*, *pop_gr*, *pop_15_64*, *life*, *pop*) are treated as exogenous while all the remaining are allowed to be endogeneous, which is based on the economic knowledge and/or intuition in this manner: the variables assumed to be exogeneous are not likely to be dependent on the economic growth in short time horizon themselves, which is why we do not decrease efficiency of the estimator by allowing their endogeneity.

Once the model (5) is estimated, the estimates $\hat{\beta}$ are known. Now in the second step, the vector of $\Delta \ln GDP_{it}$ for each $i=1, \dots, N$ can be modified so as to constitute

$$\Delta \widehat{\ln GDP}_{it} = \Delta \ln GDP_{it} - (x'_{it} - \bar{x}'_t) \hat{\beta}, \quad (6)$$

where the \bar{x}_t represent average values of all the considered growth factors throughout the sample in period t .

In the third step, the modified $\ln GDP$ series are created for each of the considered countries. In each of the cases, the modified series is defined as

$$\overline{\ln GDP}_{it} = \begin{cases} \ln GDP_{it} & t = 1 \\ \overline{\ln GDP}_{i,t-1} + \Delta \ln GDP_{it} & t = 2, \dots, T. \end{cases} \quad (7)$$

Naturally, should a group of countries be homogeneous in the sense of the values of growth factors across countries x_{it} in each of the periods $t=1, \dots, T$, the properties of the $\overline{\ln GDP}_{it}$ would be the same as of the $\ln GDP_{it}$. However, they are obviously not, thus while the absolute stochastic convergence (1) or (4) might not take place, the relative convergence, defined as

$$\lim_{k \rightarrow \infty} (\overline{\ln GDP}_{i,t+k} - \overline{\ln GDP}_{j,t+k} | I_t) = 0 \quad (8)$$

if Bernard and Durlauf's type of procedure is applied or as

$$\lim_{k \rightarrow \infty} (\overline{\ln GDP}_{i,t+k} - \overline{\ln GDP}_{t+k} | I_t) = 0 \quad (9)$$

if Pesaran's type approach is applied might occur.

As a last step we apply the same ADF test with a single lag in order to test for stationarity of the series of

$$d\overline{\ln GDP}_{i,t} = \overline{\ln GDP}_{i,t} - \overline{\ln GDP}_t \quad (10)$$

in the Bernard and Durlauf's type of approach or

$$d\overline{\ln GDP}_{ij,t} = \overline{\ln GDP}_{i,t} - \overline{\ln GDP}_{j,t} \quad (11)$$

in the Pesaran's type of approach. Rejecting the null hypothesis of non-stationarity of the series (10) or (11) would suggest that the considered economies converge stochastically in the conditional sense, while the stronger case of rejection the non-stationarity hypothesis of (2) or (3) would suggest the existence of absolute stochastic convergence. The empirical results of the above described procedures are given in the next section.

Results

The results of testing the stochastic absolute convergence hypothesis are presented in Tables 1 and 2. Table 1 refers to the convergence toward the EU28 average per capita income level while Table 2 concerns the pair-wise catching-up process.

Table 17. Results of stochastic absolute convergence toward the EU28 income level

Converging countries	<i>p</i> -value
Cyprus	0.1

The table includes only the countries that exhibited convergence, i.e those for which GDP deviations against the EU28 average were stationary. ADF test with a single lag and a constant is used.

Source: Own calculations.

It turns out that the studied countries did not reveal – in general – very strong stochastic convergence tendencies. Table 1 shows that Cyprus is the only country that converged toward the EU28 average income level. For the other 27 countries, the null hypothesis in the stationarity test could not be rejected at the 10% significance level. In the case of Cyprus, the null hypothesis was rejected meaning that the deviations of Cyprus’s GDP from the average EU28 per capita income are stationary meaning the existence of convergence.

The confirmation of stochastic absolute convergence for Cyprus may result from the fact that Cyprus is a small island country. Its economy is influenced by a lot of external factors and it exhibits stochastic convergence toward the average GDP per capita in the EU28 group.

These findings give new light on the catching-up process of the EU countries and should be treated as complementary to the other studies on convergence, based on different concepts and methods. Namely, while most cross-sectional studies on β and σ convergence confirm the existence of the catching-up process inside the enlarged European Union, in the case of stochastic convergence the results are less evident. This difference constitutes the value added of this analysis and can be explained as follows.

**Proceedings of the 8th International Conference on Applied Economics

Source: Own calculations.

First, the lack of stochastic convergence toward the EU28 average income may result from the fact that the EU group's average GDP is created by a number of countries which are homogenous in the long-run perspective but in the short run they may reveal different economic growth paths.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

Hence, due to a differentiated influence of EU members on the current pace of economic growth of the whole group, the average GDP per capita for the whole group does not match well that for the individual countries.

Second, it is also likely that the stronger catching-up tendencies would be observed toward only Western Europe rather than the EU28 as a whole. This hypothesis would require testing the EU15 per capita income level or the weighted average EU28 per capita GDP as the reference point (in the latter case, the impact of the CEE countries on the average would be much smaller and in the case of some small CEE countries – like the Baltics, Cyprus or Malta – even negligible).

Third, the lack of stochastic convergence may result from the fact that the individual countries tend toward the best performers (like Luxembourg) or the biggest economies (like Germany, France, or UK) and not toward the EU28 average. To verify this hypothesis, the pair-wise convergence should be tested that will be done in the next step of the analysis.

Fourth, it is likely that the lack of stochastic convergence results from the fact that the convergence is analyzed in absolute terms (on the basis of non-adjusted GDP per capita time series). In contrast, it may be expected that the catching-up process occurs conditionally with regard to different steady-states to which the individual countries are tending. This view will be assessed in the next steps when the conditional stochastic convergence is examined.

The results of pair-wise stochastic absolute convergence are reported in Table 2. Table 2 lists the pairs of countries for which the stochastic convergence has been confirmed. The results are symmetric meaning that if country A is converging toward country B, country B is also converging toward country A. The results of pair-wise convergence need not be similar to those toward the EU28 as already described; hence, it is worth to analyze both of them.

In the studied group of countries, the pair-wise convergence, like the convergence toward the EU28, is not very strong either. Only 8.2% of the total number of pairs of countries turned out to be statistically significant at the 10% significance level (see: Table 6). Based on the results, it is possible to identify pairs of countries for which we can find arguments that the results are not spurious. Nevertheless one should notice, that the share of rejected null hypotheses in the ADF tests is lower than the assumed significance level, which might also mean that the attained results lay within the frame of test error and despite their economic sensible interpretation, they actually are econometrically spurious. The most important findings from

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?

the analysis of Table 2 – which should still be taken with some caution – are the following.

The best performer in terms of the stochastic absolute convergence is Ireland. This country exhibited stochastic convergence with 13 Western European countries (Austria, Belgium, Denmark, Finland, France, Germany, Italy, Luxembourg, Netherlands, Portugal, Spain, Sweden, and UK) and two new EU members (Hungary and Malta). The fact that the Irish economy catches up with Western Europe is logical. Ireland has strong trade and capital links with Western Europe and this is one of the sources stimulating convergence tendencies of the Irish economy toward the other Western European countries.

Some neighboring countries with close economic links also confirm the existence of stochastic convergence. This refers to both Western Europe and the new EU member states. As regards the Western European countries, convergence has been evidenced in the case of Austria and Germany (two neighboring countries with the same language and close links), France and Spain as well as France and UK (Spain and UK are the two neighbors of France³) and UK and Ireland (countries closely linked with strong historical, political, and economic ties). As regards the CEE countries for which the convergence can be economically justified, we can enumerate Croatia and Slovenia (two former Yugoslav-republics) and – to a lesser extent – Croatia and Hungary (due to a common border).

Looking at the results of the absolute stochastic convergence some questions arise. Firstly, why Cyprus is the only country that exhibited stochastic convergence toward the EU28 average per capita income level? Secondly, why the pair-wise convergence was not evidenced in the case of some countries which should catch up due to evident historical, cultural, political, institutional, and economic relationships (like the Czech Republic and Slovakia, the Baltic states, Spain and Portugal, or the Scandinavian countries)?

To address these questions, it is worth to extend the analysis for conditional convergence. The lack of convergence in some evident cases may be caused by the fact that Tables 1 and 2 refer to the absolute catching-up process. Cross-sectional studies on β convergence indicate that absolute convergence does not show the full picture of economic growth paths of the examined countries. The main argument is that the countries tend to different steady-states because the process of economic growth is multidimen-

³ The UK is treated as the northern neighbor due to a common maritime border with France.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

sional and there are numerous factors affecting the rate of economic growth that need not be equally distributed among the considered countries. It is thus worth to verify the idea of conditional stochastic convergence, which is our new concept of the analysis.

In the case of stochastic conditional convergence, we adjust the GDP time series for each country from the impact of the given country's economic growth determinants. The adjustment is made based on the empirical model of economic growth. Initially, as described in the previous section, 10 variables were considered as economic growth determinants (and the initial GDP per capita level being the 11th variable). On the basis of the stepwise regression, two variables (life expectancy and the number of population) were eliminated due to statistical insignificance. As the result, the final model of economic growth encompasses 9 explanatory variables (including initial GDP).

Table 3 shows the estimation results of the final model of economic growth, which is used to adjust GDP per capita time series for the analysis of conditional stochastic convergence. The model given in Table 3 is estimated with the use of the Blundell and Bond (1998) GMM system estimator with the volume of GDP per capita in the current period being the explained variable.

Table 3. The model of economic growth used to adjust GDP growth rates for the stochastic conditional convergence

Explanatory variable	Coefficient	<i>t</i>-statistics	<i>p</i>-value
Initial GDP per capita	0.9732	288.94	0.000
Inv	0.0060	21.83	0.000

Constant	0.4315	7.18	0.000

Dependent variable: GDP per capita in the current period. Estimator: Blundell and Bond GMM system estimator.

Source: Own calculations.

This model is generally correct from the economic and statistical point of view. All the variables are statistically significant (*p*-values less than 0.01). The coefficient standing on initial income is less than 1 meaning that

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

in the standard untransformed economic growth model with the change in output as the dependent variable, the coefficient on initial income would be less than zero. Hence, the model confirms the existence of cross-sectional conditional β convergence (i.e. a negative relationship between the initial income level and the subsequent growth rate). Investments, trade openness and current account balance are the variables that have a positive impact on GDP growth while inflation, government consumption, population growth and fertility rate have a negative impact on the dynamics of output. These results are in line with the theoretical structural model. In the case of the share of population aging 15-64, the estimated coefficient is negative and this outcome has weaker economic background.

The results of testing the conditional stochastic convergence hypothesis, based on the adjusted GDP figures, are presented in Tables 4 and 5. Their structure is the same as that of Tables 1 and 2.

Table 4 shows the results of conditional stochastic convergence toward the EU28 average per capita income level. Now, the convergence has been evidenced for more countries than in the case of absolute convergence. In conditional terms, four countries were catching up stochastically: Croatia, Cyprus, Germany, and Ireland. As it can be seen, after introducing adjusted GDP time series, the number of converging countries increased. Among the countries that caught up, we can distinguish mainly peripheral small economies, namely Croatia, Cyprus, and Ireland. To some extent, this can be explained by the fact that small countries tend to be more open and more dependent on the other economies and it is for them easier to bridge the gap toward the average income of a given international organization. This is only our presumption because the group of converging countries includes also Germany, i.e. the biggest EU economy. In contrast, the Germany's catching-up process may result from the fact that the biggest economies determine the reference point to which the whole group is tending and that is why they are also converging to this point.

Notes as in Table 2.

Source: Own calculations.

Table 5 indicates that the pair-wise conditional stochastic convergence inside the studied group is stronger than the absolute convergence. At the 10% significance level, 10.1% of all the pairs of countries caught up while in the case of absolute convergence this share stood as 8.2% (see: Table 6).⁴ The country that exhibited the strongest pair-wise convergence is again Ireland. The Ireland's per capita GDP caught up with that of the 17 countries, two more than in the case of absolute convergence: 13 Western European economies (Austria, Belgium, Denmark, Finland, France, Germany, Italy, Luxembourg, Netherlands, Portugal, Spain, Sweden, and the UK) and 4 new EU member states (the Czech Republic, Hungary, Malta, and Slovenia).

Among the Western European countries, numerous converging partners were recorded also by Germany (Austria, Croatia, Finland, Ireland, Malta, Sweden) and France (Finland, Ireland, Spain, UK). Germany and France are the two largest EU economies (according to the 2014 total GDP at both current exchange rates and purchasing power parities). It is thus likely that these countries reveal a large impact on economic growth paths of the other EU members and that is why they have relatively many converging neighbors. As regards the new EU member states, the biggest number of converging partners had some peripheral economies, namely Bulgaria (5 countries), and Croatia and Malta (both 3 countries).

Just like in the case of absolute convergence, it is also possible to find some pairs of countries exhibited conditional catching up where the convergence has strong historical, political, and economic background. This refers to Austria and Germany, Croatia and Slovenia, France and Spain, France and UK, as well as Ireland and UK. However, some other theoretically evident cases (like the Baltics or the Scandinavian countries) have not been converging in pairs.

⁴ Theoretically, the pairs showing absolute convergence should also reveal conditional convergence. However, when examining empirical data for the real economies such a situation need not hold due to, inter alia, the nature and assumptions of quantitative methods in macroeconomic modelling.

Table 6. Robustness tests: the share of converging pairs of countries at different significance levels

<i>p</i> -value	Pair-wise absolute stochastic convergence	Pair-wise conditional stochastic convergence
0.01	4.5%	5.0%
0.05	6.3%	7.1%
0.10	8.2%	10.1%

The total number of different pairs is $(28 \times 28 - 28) / 2 = 378$. ADF test with a single lag and a constant is used.

Source: Own calculations.

Finally, a robustness analysis to check how the results are affected by introducing different significance levels can be performed. Table 6 shows the share of converging pairs of countries for the three significance levels: $p = 0.01$, 0.05 , and 0.10 , while the last figure has been adopted in the main analysis in Tables 2 and 5. These p -values refer to the stationarity tests where the null hypothesis assumes that both time series are non-stationary, that is they are not converging. Hence, the confirmation of convergence requires the rejection of the null hypothesis. The lower the p -value, the lower number of rejected null hypotheses, and the lower number of confirmed pairs of converging countries. Indeed, under the basic p -value of 0.10 , 8-10% of total examined pairs of countries exhibited stochastic convergence. At the p -value of 0.05 , the share of converging countries falls to 6-7%, while at $p = 0.01$ it falls to 4-5%. That means that in most cases, except the low 0.01 significance level, the rate of rejection in the tests does not differ much from the assumed level of significance. Following the rationale of Pesaran (2007), such a result in asymptotic conditions would suggest no converging tendencies. The number of time periods in the sample is quite far from the number that would allow us to treat the conditions as asymptotic, nevertheless, all in all we should admit a failure to find any well palpable converging tendencies.

Summing up, our analysis shows that the process of stochastic convergence in the EU countries is not as widespread as the cross-sectional studies on β or σ convergence indicate. Even if we extend the analysis to examine conditional stochastic convergence (the original approach proposed by the authors of this study), the number of converging economies or pairs of countries rises but not as much as it could be expected from the cross-sectional studies. These results also confirm the theoretical Bernard's and Durlauf's (1996) view that time series tests are based on a stricter notion of convergence than cross-section tests.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

This analysis gives new insights into the nature of economic growth paths of the examined countries. The results indicate that our concept of conditional stochastic convergence is a good idea. It shows a broader picture of economic growth tendencies than the absolute convergence hypothesis and it has been worth to examine it. However, the methods of analyzing conditional stochastic convergence require further theoretical developments and empirical applications to check the robustness of the results.

Conclusions

The study examines the concept of stochastic convergence in the EU28 countries over the 1994-2013 period. The stochastic convergence means that the expected value of future differences between the GDP per capita levels in different countries is zero in the infinite time horizon. In the paper, the convergence of individual countries' GDP per capita toward the EU28 average per capita income level and the pair-wise convergence between the GDP of individual countries both are analyzed. Additionally to the standard Bernard's & Durlauf's (1995) and Pesaran's (2007) approach, we introduce our own concept of conditional stochastic convergence which is based on adjusted GDP per capita series to account the impact of the other growth factors on GDP. To test for stationarity of the series of differences between the GDP of a considered country and mean GDP of the whole group as well as differences of the GDP of the two countries, ADF tests are used.

The analysis shows that the process of stochastic convergence in the EU countries is not so widespread as the cross-sectional studies on β or σ convergence indicate. Even if we extend the analysis to examine conditional stochastic convergence, the number of converging economies toward the EU28 group's mean GDP rises from 1 to 4 and the share of converging pairs of countries rises from 8.2% to 10.1%; this is still not as much as it could be expected from the cross-sectional studies.

Globalisation Effect Measure via Hierarchical Dynamic Factor Modelling

JEL Classification: *C43; E32; C10*

Keywords: *leading indicator; hierarchical dynamic factor model; globalisation; economic growth*

Abstract: In this paper the issue of globalisation and deteriorating precision of domestically oriented frameworks is addressed. A hypothesis that the effect of international trends on the growth of economy is increasing over time is formed. In order to validate this a method of composing foreign series with local indicators in a hierarchical dynamic factor model is presented. The novelty of this approach is that globalisation effect is measured focusing on prediction rather than similarity. This way the measure presents country's sensitivity to global shocks and reveals how much focal country's economy is intertwined with global economy. The application was performed on Lithuanian data and the hypothesis was validated. The results indicate that globalisation effect has an increasing effect over time.

Introduction

The globalisation is increasingly addressed as the underlying cause of diminishing accuracy of traditional domestically oriented macro-econometric models. An example of extended Conference Board methods (Drechsel and Sheufele, 2010) shows that more and more indicators have to be incorporated into leading index construction to keep up with the accuracy of previously constructed models. This result could indicate that

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

processes are becoming of more complicated structure impelled by increasing amount of information available for a single agent of economy and therefore affecting its decision-making. The accuracy of domestically oriented models deteriorates with time and this phenomenon is addressed by Fichtner et al. (2009). They find that it is caused by globalisation, however adding information about external environment improves the forecast performance.

Globalisation measure has been constructed by other authors although with different focus. Deher et al. (2008, pp. 25-74) label globalisation as multi-domain, pluralistic phenomenon which consists of many processes so they take a complex approach to construct index based on many indicators which reveal globalisation presence. Kearney (2004) globalisation index is canonical example of such measure it is aggregate weighted index calculated from indicators of areas: political engagement, technology, personal contact and economic integration. This index is quantitative but heavily relies on weighing and this weakness is often addressed by other authors, e.g. Lockwood (2004, pp. 507-623), Heshmati (2006). This index is also criticised for not being clear of what exactly it measures and that indicators from different countries are calculated using different methodologies therefore not possessing the desired feature of cross-comparability (Castelli, 2008, pp. 383-404).

Another approach to measure globalisation is based on international trade, e.g. Naghshpour and. Sergi (2009, pp. 1-24) created an index by classifying and ranking the countries on their imports and exports or international trade share to GDP. This method is useful for comparing countries but does not contribute to the dynamic aspect and does not address globalisation in the time domain. Another example of using international trade to inspect and measure the globalisation is study by Kim and Shin (2002, pp. 445-468). Their method was network based and revealed interesting patterns in geographical domain. They also compared 2 time periods (1959 and 1996) and made generalisations about globalisation process from them: the international trade is becoming denser due to globalisation.

The similarity in dynamics of economic indicators in different countries could be measured in various ways, but the most popular method is some sort of factor modelling. The findings of Cubadda et al. (2012) show that a common factor explains a lot of co-movements of different European countries therefore including data of other countries could help acquire better accuracy in evaluating models, since the factor model approach is

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

data greedy. Andersen and Herbertsson (2003, 2005, pp. 1089-1098) analysed indicators of economic integration, applied used factor analysis to measure the commonality across different countries and calculated the index of globalisation. Similar results were acquired by Maslov (2001, pp. 397–406) using the similar methods (principal component analysis) on financial time series.

The findings of mentioned authors suggest that the component of foreign information in economic models is gaining more importance. Statistical explanation for this could be that the foreign component of these processes was always present, but was discarded as insignificant, because of its noise-like features. However due to globalisation indicators from different economies are becoming more similar and supranational element is becoming more apparent. This effect should be particularly visible for small open economies.

In the light of these statistical observations it was decided to take a new approach on measuring the globalisation effect with the focus on prediction. Other authors like Andersen and Herbertsson (2003) measure the similarity of economic indicators across different countries. However this way the 'globalisation effect' might be represented by spurious relationships. Therefore prediction based measurement could indicate country's sensitivity to global shocks and reveal how much focal country's economy is intertwined with global economy. This way we could define what we want to measure: the globalisation impact as a proportion of economy growth explained by supra-national factors.

The relationship between globalisation and the growth of economy has been analysed by many authors, e.g. Dreher (2006, pp. 1091-1110) found that globalisation promoted economic growth, Quinn's and Toyoda's (2008, pp. 1403-1449) findings reveal that capital account liberalization had a positive association with growth in both developed and emerging market nations, Villaverde and Maza (2011, pp. 952-971) conclude that globalisation has been one of the main drivers of economic growth. These authors mostly distinguished relationship between the degree of globalisation measured by Kearney or similar indexes and the growth rates of economy. The novelty of this paper is that it tries to reveal what part of the economic growth was generated from drivers of globalised economic environment and measure this effect in the time domain so that the monitoring of the globalisation impact could be performed. Another issue that is addressed in this paper is the dynamics of measured globalisation effect: does it grow in magnitude?

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

The main hypothesis in this study is: the effect of international trends on the growth of economy is increasing over time. In order to distinguish and quantify domestic and foreign factors the structural approach is required and a dynamic hierarchical factor model was built following Moench et al. (2009).

The main objectives of this paper are the following:

- Adapt the hierarchical dynamic factor model to distinguish and evaluate the effect of domestic and foreign drivers of the economy and attain a quantitative measure of magnitude of either effect in the time domain
- Apply the new method for Lithuanian data
- Validate the hypothesis that due to globalisation the proportion of economic growth forecast explained by foreign indicators is increasing over time

The introductory paragraph outlines clearly state the objectives and motivation for writing the paper. The introduction should provide a context for the discussion in the body of the paper.

Methodology of the research

Since the main objectives are to determine the load of domestic and foreign drivers on the growth of focal economy the leading indicators approach is used. The GDP growth was used as a measure for economy growth. The leading series are identified on several criteria (correlation, Granger causality, ect.) and used in the following steps of study after necessary transformations (stationarisation and scaling).

The structural methods are necessary in order to distinguish domestic and foreign components of economy drivers. For this reason it was necessary to enforce structural division of domestic and supra-national indicators and hierarchical dynamic factor model served that purpose very well. The time series were organised into 2 blocks: one for domestic and the other for foreign indicators. The evaluation of this model was performed using Monte Carlo Markov Chain (MCMC) simulations with Gibbs sampling technique assuming gaussian innovations.

After the evaluation of domestic and foreign factors a dynamic linear model was built to identify time-varying weights of domestic and foreign factors on the growth of GDP. The initial values were selected upon regressing GDP growth on evaluated factors.

The leading indicators

Since the global economic environment is described by many indicators the Stock and Watson (2002) method for macroeconomic forecasting using diffusion indexes was chosen. This method allows to use many predictors which could be cumbersome for some traditional techniques such as vector auto-regression or structural equation modelling. The factor model also deals with an issue of indicators being not suitable for cross-comparability (due to different methodologies of measurement in different countries) addressed by Castelli (2008, pp. 383-404). Factor model lets us extract signal from large panel of data series therefore discrepancies caused by different measurement methods are discarded as noise.

The selection of leading indicators was performed following Gaudreault et al. (2003). An initial data set consisted of almost all Lithuanian quarterly economic indicators starting at least at 1998 (this date was important since there was a recession in 1998-1999 and it would be interesting to monitor the results in this particular period), and the major economic indicators of Lithuania's top 20 international trade partners. Leading series were selected based of three criteria:

1. Granger causality
2. Correlation between series $\Delta X_{i,(t-l)}$ and GDP growth ΔGDP_t should be greater with lags $l > 0$
3. R^2 criterion should be bigger in regression $\Delta GDP_t = \Delta X_{i,t-l} + e_t$ with lags $l > 0$

Only the series that met all three criteria were selected. A three level model was built and separate factors were estimated for domestic and foreign variables since the domestic series were organised into one block, while another block contained the foreign series. The domestic block consisted of 4 time series and foreign block was formed from 20 series. The domestic leading indicators largely overlapped with selected leading indicators from another study where they were used for constructing Lithuanian leading economic index (Reklaite, 2011, pp. 91-107).

The hierarchical factor model

The equations constituting the three level hierarchical model are the following:

$$X_{bit} = \Lambda_{G,bi}G_{bt} + e_{Xbit} \quad (1)$$

$$G_{bt} = \Lambda_{F,b}F_t + e_{Gbt} \quad (2)$$

$$\psi_F(L)F_t = \varepsilon_{Ft} \quad (3)$$

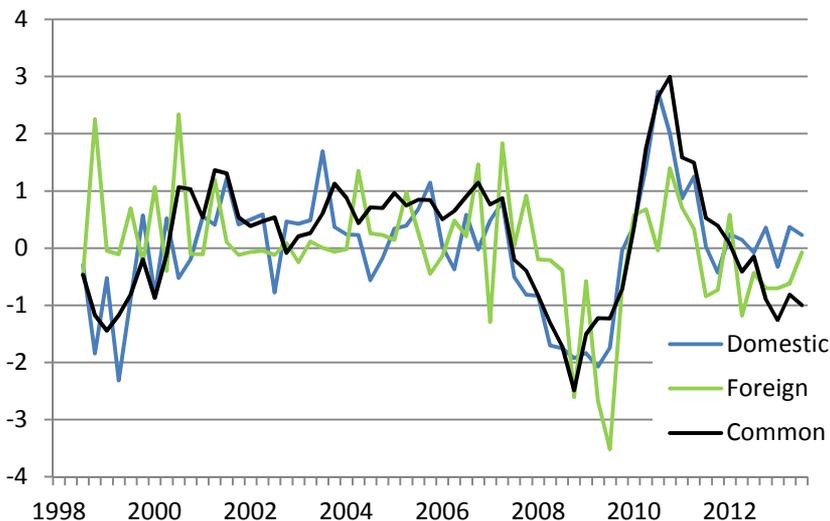

X_{bit} are leading series, which were transformed to be stationary and scaled, index b denotes the block (either domestic or foreign), i - index of time series, t denotes time index. Λ_G and Λ_F are loadings, G_{bt} are block-level factors, F_t is a common factor. The equation (3) describes stationary AR(1) process. e_{Xbit} , e_{Gbt} and ε_{Ft} have zero mean and their variances $\Sigma_X = cov(e_{Xbit})$ and $\Sigma_G = cov(e_{Gbt})$ are assumed to be diagonal. The evaluation of this model was carried out following the procedure by Moench et al. (2009), via Markov Chain Monte Carlo (MCMC) using Gibbs sampling technique (Carter and Kohn, 2004, pp. 541-553), under assumption of Gaussian innovations. Data series are structured into blocks $b = 1, \dots, B$. Each series i in a given block b is decomposed into a serially correlated idiosyncratic component e_{Xbit} and a common component $\Lambda_{G,bi}(L)G_{bt}$ which it shares with other variables in the same block. Each block level factor G_{bjt} has a serially correlated block-specific component e_{Gbjt} and a common component $\Lambda_{F,bj}(L)F_t$ which it shares with all other blocks. Finally, the economy-wide factor F_t is assumed to be serially correlated. In this model, variables within a block can be correlated through F_t and the e_{Gbjt} 's, but variables between blocks can be correlated only through F_t . Estimation procedure by MCMC: Let $\Lambda = (\Lambda_G, \Lambda_F)$, $\Psi = (\Psi_F, \Psi_G, \Psi_X)$, $\Sigma = (\Sigma_F, \Sigma_G, \Sigma_X)$.

1. Organize data into blocks to yield X_{bt} , $b = 1, \dots, B$. Use principal components to initialize $\{G_t\}$ and $\{F_t\}$. Use these to produce initial values for Λ , Ψ and Σ .
2. Conditional on Λ , Ψ , Σ and $\{F_t\}$ draw $\{G_t\}$ taking into account time varying intercepts.

3. Conditional on Λ , Ψ , Σ and $\{G_t\}$ draw $\{F_t\}$.
4. Conditional on $\{G_t\}$ and $\{F_t\}$, draw Λ , Ψ and Σ
5. Return to 2.

One dynamic factor for each block and one common factor were evaluated. 10000 iterations were made, and first 500 were dropped out as a "burn-in". The domestic and foreign leading factors were evaluated calculating the expectation from posterior distributions. The estimations were carried out using *dlm* package (Petris, 2010) of statistical software *R*. The resulting factors are plotted in figure 1.

Figure 1. Evaluated common, domestic and foreign leading factors from the hierarchical factor model

Source: own work.

The results indicate that even though the extracted domestic and foreign factors are a bit noisy, they depicted the economic crisis and recovery in 2007-2011 pretty well. As expected, domestic and foreign factors have similarities with common factor (domestic factor $G_{1,t}$ correlates with common factor by 0.88, foreign factor $G_{2,t}$ correlates with common factor F_t by 0.56). Even though correlation between $G_{1,t}$ and $G_{2,t}$ is positive (0.29) they have periods where they act opposite of each other, which is

imminent since model specification allows them to correlate only through the common factor F_t .

Combining the indexes

To determine the magnitude of the effect of domestic and foreign drivers to the Lithuanian economy, a simple linear model was built following macroeconomic forecasting example by Stock and Watson (2002) by regressing the growth of coincident index on both leading factor estimates. The 1-period ahead forecast was made:

$$\Delta GDP_{t+1} = \alpha_1 G_{1,t} + \alpha_2 G_{2,t} + \varepsilon_{t+1} \quad (4)$$

The estimates of parameters are in the table 1.

Table 1: Estimates of model parameters from equation (4)

	Estimate	Std. Error	t value	p-value
α_1	0.297	0.113	2.639	0.010
α_2	0.399	0.113	3.543	0.001

Source: own work.

Here $G_{1,t}$ was a the domestic leading factor, and $G_{2,t}$ was the foreign leading factor. It can be identified from table 1 that foreign factor has a larger load on the future state of economy which is not surprising since the focal economy is small and open.

Dynamic linear model

Equation (4) was evaluated under the assumption that the coefficients are fixed over time. Relaxing this assumption lets us build a dynamic linear state-space model to identify how the effects of domestic and foreign drivers of economy change over time and validate the hypothesis that the proportion of economic growth forecast explained by foreign indicators is increasing over time:

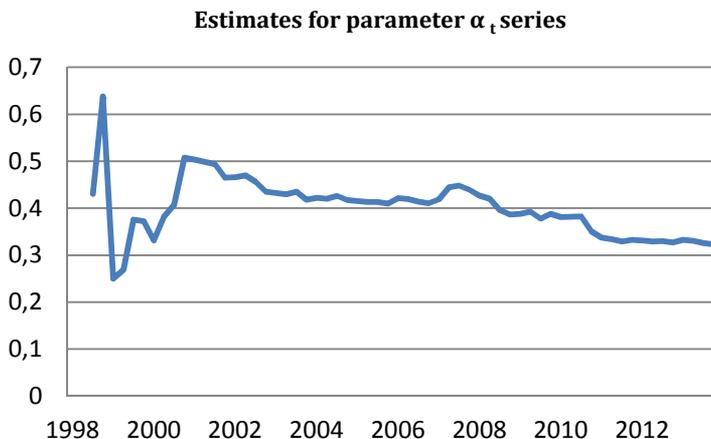

$$\Delta GDP_{t+1} = \alpha_t G_{1,t} + (1 - \alpha_t) G_{2,t} + \varepsilon_{t+1}, \quad (5)$$

$$\alpha_{t+1} = \psi\alpha_t + u_t. \tag{6}$$

The parameters at $G_{1,t}$ and $G_{2,t}$ were constrained to sum to 1 in order to make this model identifiable. Under this specification our hypothetical statement means that the parameter α_t should be declining over time since $G_{1,t}$ is domestic factor. The parameters of this model were evaluated by maximum likelihood (assuming Gaussian innovations) and Kalman filtering. The prior value of α was set to match result from regression (4). The plot of dynamic coefficient α_t is in the figure 2.

It can be identified from graph 2 that the Russian crisis of 1998-1999 had huge impact. Also, it shows that parameter α_t is decreasing, which means that Lithuanian economy is more and more intertwined with other European economies. This result also validates our hypothesis about the increasing amount of explained forecast by foreign indicators. It leads to a conclusion that globalisation makes quantifiable and increasing effect in focal economy.

Figure 2. Evaluated parameter series α_t - the parameter of domestic factor impact in future economy

Source: own work.

Conclusions

In this paper a hypothesis was formed: due to globalisation the proportion of economic growth forecast explained by foreign indicators is increasing over time. In order to validate it a hierarchical dynamic factor model was built. Using this structural approach the domestic and foreign drivers of economy were distinguished and their effects quantified. This measure offers a new view at globalisation since it is measured focusing on prediction rather than similarity and reveals how much focal country's economy is intertwined with global economy in terms of how sensitive it is to global shocks.

This new measure has a clear interpretation and withstands critique aimed at many other measures, such as obscurity of what exactly they measure, or lack of robustness in spite of their strong reliance on weighting and indicator selection. The factor model also deals with issue of data quality in sense of lacking measurement precision and infeasible indicators from different countries on the grounds that it extracts the signal from large data panels and discrepancies are recognized as noise.

Lithuanian example showed that foreign series correspond to an amount which is increasing over time. This confirms not only that incorporating foreign data is useful, but also that in this framework the globalisation effect is visible and it can be monitored using dynamic linear models. These conclusions state that the hypothesis was validated and foreign information corresponds to an amount of forecast explained that is increasing over time.

Optimization of the Variables Selection in the Process of Real Estate Markets Rating*

JEL Classification: *B16*

Keywords: *real estate market rating; optimization of the variables selection; Hellwig's method*

Abstract: The growing significance of the real estate market prompts investors to search for factors and variables which support cohesive analyses of real estate markets, market comparisons based on diverse criteria and determination of market potential. The specificity of the real estate market is determined by the unique attributes of property. The Author's assume that developing real estate market ratings identifies the types of information and factors which affect decision-making on real estate markets. The main objective of real estate market ratings is to create a universal and standardized classification system for evaluating the real estate market. One from the most important problem in this area is collection of appropriate features of real estate market and development dataset. The main problem involves the selection and application of appropriate features, which would be relevant to the specificity of information related to the real estate market and create a kind of coherent system aiding the decision-making process. The main aim of this study is to optimization of variables set that were used to develop the real estate market ratings. To this purpose Hellwig's method of integral capacity of infor-

mation was applied. In this particular case, this method shows what set of variables provides information most sufficiently. The results lead to obtain the necessary set of features that constitute essential information which describes the situation on the local real estate market.

Introduction

The real estate market is one of the most rapidly developing goods markets that attract massive investments, but as an object of research, it poses numerous problems.

The level of knowledge about the market and its participants is a factor that determines the efficiency of the real estate market, but is often disregarded in market analyses. Knowledge gaps may originate with active market participants who have limited information about the system and its constituent elements. Other market participants may also have limited knowledge in this area. The knowledge manifested by entities conducting transactions on the RE market is (according to theoretical assumptions) limited or negligent. The above implies that market participants conduct transactions without mutual knowledge which leads to asymmetry in the decision-making process. This could lower the efficiency and, consequently, the effectiveness of the entire market. Researchers analyzing the real estate market should also demonstrate a sufficient level of knowledge about the mutual relationships between the subjects and objects of market transactions (Renigier-Biłozor, Wiśniewski, 2012, str. 95-110).

Providing access to the knowledge of the real estate market developed in the form of a simple message is the only way to solve this problem. The authors assumed that it can be achieved by developing a measure of the rating real estate markets providing general and unambiguous/clear information classifying the object of analysis and being an effective decision-making support system.

The specificity of the real estate market is determined by the unique attributes of property. For this reason, rating methodologies applied on capital markets cannot be simply copied to the real estate market.

The main objective of real estate market ratings is to create a universal and standardized classification system for evaluating the real estate market. A rating system contributes to objectivity in the decision-making process and it shortens decision-making time (Renigier-Biłozor et al., 2014).

Real estate market ratings serve a variety of practical purposes. They are used to develop portfolio investment strategies (Anglin and Yanmin, 2011, Collett, Lizieri and Ward, 2003) and formulate long-short portfolio strate-

Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

gies on housing indices for more risky and less risky assets characterized by low liquidity (Berach and Skiba, 2011). The scarcity of relevant information results from the shortcomings of market effectiveness analyses (Case and Shiller, 1989, Fama, 1990, Grossman and Stiglitz, 1980, Dawidowicz and oth 2014). According to Case and Shiller (1989, 1990), the ineffectiveness of the analyzed market can be attributed to individual investors who do not have access to objective knowledge about the real estate market.

One from the most important reasons behind undertaking research in this area is the problem which occurs in the advanced real estate analysis, as collection of appropriate features of real estate market and development dataset. Market features are usually divided into macroeconomic and microeconomic factors, including socio-demographic development, overall economic development and political, legal condition and property market. The main problem involves the selection and application of appropriate features, which would be relevant to the specificity of information related to the real estate market and create a kind of coherent system aiding the decision-making process.

The main aim of this study is to verify the variables that were used to develop the real estate market ratings in the author's previous work entitled: "Rating methodology for real estate markets - poland case study" (Renigier-Biłozor et al., 2014). At this target Hellwig's method of integral capacity of information was applied. This method, in this particular case it is showing, what store of features are providing information with the almost full source.

The results lead to obtain the necessary set of features that constitute essential information which describes the situation on the local real estate market.

The study was prepared as a result of implementation of research project No. UMO-2014/13/B/HS4/00171 financed from the funds of the National Science Centre.

Methodology of the research

Although recent year have witnessed the growing popularity of various support systems, comprehensive and effective information systems that facilitate real estate management and analyses continue to be in short supply. The above results from the specific character of real estate management operations which involve complex procedures and decisions, as well

as the unique character of real estate data. Those factors prevent smooth flow of information which is required for the implementation of rational decisions and actions in business, investment, financial and promotional projects (Renigier-Biłozor, 2013).

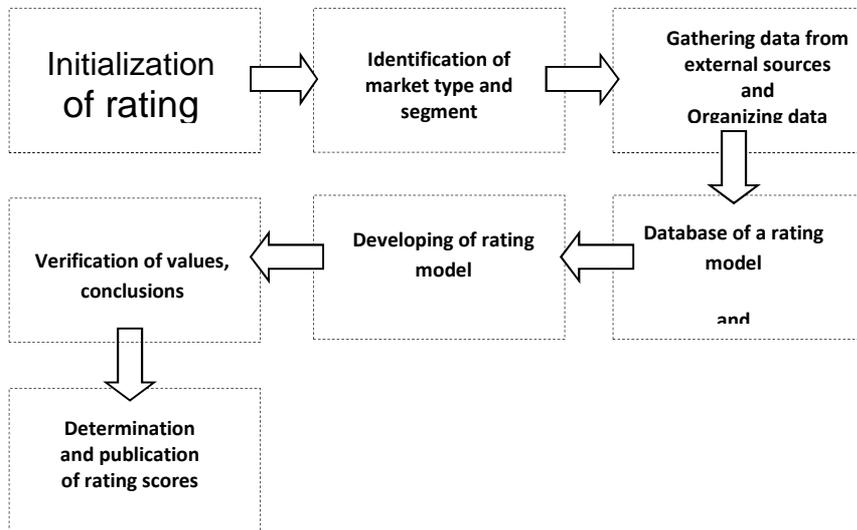

The growing significance of the real estate market prompts investors to search for factors and variables which support cohesive analyses of real estate markets, market comparisons based on diverse criteria and determination of market potential. Investors search for similarities that would enable them to develop risk minimizing strategies. Ratings are a modern tool that can be deployed in analyses and predictions of real estate market potential.

The Author's assume that developing real estate market ratings identifies the types of information and factors which affect decision-making on real estate markets. The detailed objectives of developing scoring systems for real estate markets are: to introduce objective benchmarks for comparing real estate markets, to reduce the number of variables in the decision-making process, to evaluate real estate markets' potential for economic and spatial growth, to evaluate social benefits/losses resulting from the development of a given real estate market, to provide for effective flow of information about the real estate market.

A rating methodology has to be adapted to the specific attributes of a real estate market. A general diagram of a real estate market rating procedure is shown in Fig. 1.

The diagram has been expanded to include detailed information about the type of the analyzed real estate market, its structure and functions. A detailed diagram can be then used to evaluate any real estate market. Rating scores are diversified for different market types and market segments at the level of rating variables, i.e. information and factors describing real estate functions. The proposed system has a modular structure to ensure greater methodological openness. A given market can be rated with the involvement of all or selected modules.

Figure 1. Diagram of a rating procedure.

Source: Own study based on Renigier et al., (2014).

In this study, we assume that the type and the segment of the real estate market are identified, and the utility function of real estate is determined. Market type is indicative of the utility function of real estate: investment market, commercial market, industrial market, agricultural market. etc. Market segment accounts for a specific group of real estate which is identified in a given type of a market in view of its utility function. A real estate market would be very difficult to rate without prior classification. The aim of the proposed division is to introduce a certain degree of uniformity to the rating procedure. The main standardizing factor is the utility function of the market and real estate, which implies that markets will be evaluated based on their utility rather than legal status (Renigier et al., 2014).

In order to collect appropriate data set of variables that diagnosed situation on the residential real estate market the many publication (Kaklauskas et al. (2011) Irwin et al. (1993), Jaffe and Sirmans (1989), Bryx and Matkowski (2001), Case (2000) , Żróbek and Grzesik (2013)) has been analyzed. The authors compiled the existing knowledge to propose an indicator sets for evaluating the real estate markets (table 1) that identify the types of information and factors which affect decision-making on real estate markets.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

Mainly residential real estate market is selected for the analysis, due to the lack of such solutions on the market, and the universality of participation from the viewpoint of customers.

Since the main aim of a rating is to provide quick, objective, reliable and updated information, a dataset has to be developed as a platform for quantitative and qualitative analyses. In view of the specific character of the real estate market, the availability of market information and the sudden and unpredictable changes that often occur on that market, the developed system for gathering market data should be flexible enough to enable frequent modifications.

From the analytical point of view, the solution to the problem requires the selection of appropriate methods for analyzing the available information rather than, as it is often observed in practice, the adaptation of the existing information to analytical methods. In the era of globalization, quick and unified solutions (procedures, algorithms) are needed to enhance the objectivity and the reliability of research results. The preferred solutions should address the problem on a global scale while accounting for the local characteristics of the analyzed markets and the relevant information.

In this case, the authors suggest use of Hellwig's method (Hellwig, 1976) as a tool for determining an optimum set of variables to evaluate real property market rating.

The heuristic proposed by Hellwig (1969) takes into account both class feature correlation and correlation between pairs of variables. The best subset of features is selected from among all possible subsets that maximizes the so-called "integral capacity of information.

**Development of an optimal set of variables to assess
the rating of real estate market**

Residential property (apartment) markets in capital cities of Polish regions were rated in this study.

The dataset for the residential property market was developed for supply and demand categories (Table 1 and 2) based on the available information.

x1 - local government's spending on housing policy in zł, x2 - total number of issued construction permits, x3 - number of issued construction permits, x4 - number of property offers per 1000 residents, x5 - ratio of replacement value per 1 m² of property to the average price quoted on the local real estate market, x6 - number of property offers, x7 - number of developers on the local market, x8 - affordability of rental housing in m², x9 - difference between the average prices of new and second-hand property, x10 - number of deaths (older than 50), x11 - existing residential area per 1 resident, x12 - number of residents per 1 existing apartment, x13 - number of new apartments per 1000 residents, x14 - percent of land covered by zoning.
Source: own study based on Renigier et al. (2014).

Rating scores were determined individually for supply and demand with utilization of rough set theory and Ward's cluster analysis and statistical measures. In mentioned study assumed that real estate markets are scored on a 10-point rating scale and are divided into four rating level groups: investment, development, stagnant and crisis. Except for the crisis level group which has a single score – D, there are three scores per each group: AAA/BBB/CCC, AA/BB/CC and A/B/C. Scores AAA/BBB/CCC represent the highest rating, AA/BB/CC – a medium rating, and A/B/C – the lowest rating in a given group. Plus (+) and minus (-) signs may be appended to rating symbols to indicate their relative position within each group. Numerical values were assigned to every rating score to facilitate calculations: AAA – (1), AA – (2), A – (3), BBB – (4), BB – (5), B – (6), CCC – (7), CC – (8), C – (9) and D – (10).

Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

The result of this work was the elaboration of average rating scores that were determined for the analysed markets for demand and supply (Table 3).

Table 3. "Average rating scores" for the analyzed real estate markets

Markets	Rating of supply		Rating of demand	
Gdańsk	4.07	BBB	4.52	BB+
Olsztyn	6.00	B	5.42	BB-
Szczecin	4.86	BB	5.47	BB-
Bydgoszcz	6.07	B	5.61	B+
Białystok	5.50	BB-	5.71	B+
Poznań	4.64	BB+	4.80	BB
Warsaw	3.07	A	3.42	A-
Łódź	5.36	BB-	5.89	B
Wrocław	3.64	BBB+	4.76	BB+
Lublin	5.28	BB-	6.19	B
Kraków	4.00	BBB	4.67	BB+
Rzeszów	5.14	BB	5.42	BB-
Zielona Góra	5.71	B+	5.71	B+
Kielce	5.71	B+	6.27	B-
Katowice	5.43	BB-	5.33	BB-
Opole	6.36	B-	6.28	B-

Source: own study based on Renigier (2014).

Efficiency of presented studies depends, in a significant degree, on availability of data, data reliability and uniformity. The analysed phenomenon is very complex in its nature and requires collection of a lot of varied data. This is related to significant labour outlays, as well as the necessity of incurring significant costs.

The objective of this study is to determine an optimum set of information indispensable for preparing a rating assessment. In the presented scheme No. 1, this is a module related to the database of a rating model and data verification. In the original study (Renigier ... 2014), it was not possible to verify the significance of variables on account of absence of dependent variable. Therefore, assuming the result of a rating in numerical form as a dependent variable, analysis of significance of the accepted information divided into demand and supply nature of the market was adopted.

For the purpose of finding an optimum combination of explanatory variables – combinations with greatest integral information capacity index, Hellwig's method was applied. At the beginning, the Pearson's correlation coefficient was calculated for demand and supply indices (explanatory var-

variables) with respect to the demand rating (Table No. 4) and supply rating (Table No. 5).

Table 4. Correlation scores for real estate rating of demand

Demand variables	Correlation scores with rating of demand
average purchasing power in comparison with the national average	0,75
local government's spending per 1 resident in recent years	-0,70
difference between the national average salary and the average salary on the local market	-0,69
local government's spending on promotion	-0,34
changes in local property prices	-0,01
ratio of replacement value of 1 m2 of property and the average transaction price on the local real estate market	-0,24
number of property transactions per 1000 residents	-0,57
purchasing power on the local housing market	0,23
changes in local property prices	-0,01
ratio of replacement value of 1 m2 of property and the average transaction price on the local real estate market	-0,24
average time on the market in months	0,34
number of real estate agents on the local market	-0,79
availability of mortgages in terms of m2	-0,22
value of property transaction per 1 resident on the local market	-0,72
population density per m2	-0,45
number of marriages	-0,80
number of divorces	-0,83
net migration rate	-0,69
population growth	-0,37
age structure of potential clients (25-45 population group vs. total population in a given area)	-0,81
unemployment rate	0,70
quality of life	-0,53
number of new registered businesses per 1000 residents	-0,74

Table 5. Correlation for supply of real estate rating

Supply variables	Correlation scores with rating of demand
local government's spending on housing policy in zł	-0,34
total number of issued construction permits	-0,89
number of issued construction permits	-0,73
number of property offers per 1000 residents	-0,75
ratio of replacement value per 1 m2 of property to the average price quoted on the local real estate market	-0,65
number of property offers	-0,78
number of developers on the local market	-0,81
affordability of rental housing in m2	0,45
difference between the average prices of new and second-hand property	0,55
number of deaths (older than 50)	-0,76
existing residential area per 1 resident	-0,61
number of residents per 1 existing apartment	0,62
number of new apartments per 1000 residents	-0,49
percent of land covered by zoning	-0,21

Source: own study based on Renigier 2014.

Subsequently, the matrix of correlation coefficients was determined among explanatory demand (Table No. 6) and supply (Table No. 7) variables.

On this basis, individual indices of information capacity were determined for each combination according to the following formula:

$$h_{kj} = \frac{r_j^2}{1 + \sum_{\substack{i=1 \\ i \neq j}}^m |r_{ij}|} \quad (1)$$

r_j - correlation between Y and X_j

r_{ij} - correlation between X_i and X_j

k - number of combinations, $k = 1, 2, \dots, l$

j - variable number of combinations $j = 1, 2, \dots, m$

Finally, integral information capacity indices should be determined for each combination according to the following formula:

$$H_k = \sum_{j=1}^m h_{kj}, \quad k = 1, 2, \dots, l \quad (2)$$

The optimal set of information indicates from combination of variables with the highest H_k .

every variable on the result of the integral information capacity (Hi) was verified. The total integral information capacity (Ht) (with all variables) was compared with individual integral information capacity (Hi) (after deleting each variable) respectively. These deleted variables with individual indicators bigger than the total indicator were removed (bold font - table No. 8 and 9). The analysis indicated that the remaining variables constituted the combination of optimal set with the highest integral information capacity (Ho) (table No.8 and 9).

Conclusions

The authors prepared analyses of verification of variables that were used to develop the real estate market ratings. To this purpose Hellwig's method of integral capacity of information was applied. The mentioned method enables to choose the optimal combination of variables with the highest information capacity integral indicators. The results lead to obtain the necessary set of features that constitute essential information which describes the situation on the local real estate market.

The conducted analyses indicate that the most optimal set of indicators for demand rating comprises: average purchasing power in comparison with the national average, difference between the national average salary and the average salary on the local market, local government's spending on promotion, number of property transactions per 1000 residents, average time on the market in months, number of real estate agents on the local market, value of property transaction per 1 resident on the local market, number of marriages, number of divorces, net migration rate, age structure of potential clients (25-45 population group vs. total population in a given area), quality of life, number of new registered businesses per 1000 residents and for supply rating: local government's spending on housing policy in zł, total number of issued construction permits, number of property offers per 1000 residents, ratio of replacement value per 1 m² of property to the average price quoted on the local real estate market, existing residential area per 1 resident, number of new apartments per 1000 residents.

Demographic Changes in Poland – the Regional Dimension

JEL Classification: *J11; J14; R11*

Keywords: *demographic changes; population ageing; regional diversity of ageing*

Abstract: The progressive ageing process concerns both Poland and the other Member States of the European Union. In recent years, the share of workers of non-mobile and post-productive age in the total population has been rising, and according to forecasts, in 2035 people aged 45 years and over will represent two-thirds of our society. Since the year 2012, announced the Year of Active Ageing and Solidarity between Generations by the European Commission, more and more attention has been paid in the Polish public space to the issues of an ageing society, including its impact on the health of the economy.

The article notes that the ageing process does not occur uniformly across all Polish regions, i.e. at the same pace and with the same intensity. The results of studies indicating the regions being most vulnerable to the ageing of the regional community and the negative consequences of this process in the next two decades are presented.

Introduction

The ageing of society is a global phenomenon (Lee, 1994, pp. 8-49), although its pace is different in different parts of the world, countries and regions (Population Division of the United Nations, 2013; Heran, 2013, pp. 13-20; Żołądowski, 2012, p. 30). The society is ageing (Stańczak, 2014) if

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

the share of seniors in the total population is rising¹. According to Rosset (1959), the population reaches the so-called demographic senility when the population aged 60 years or more comprises at least 12% of the total population. The measures of an ageing population may also be the fertility rate below the generation replacement rate, decreasing mortality among the elderly, increasing median age of the population (Suntoo, 2012), as well as increasing life expectancy and life in good health expectancy (Burzyńska et al., 2010, pp. 530-536).

The ageing of the population is affected by many factors. Among the basic ones, the literature mentions: the decreasing number of births and fertility rates and increasing life expectancy (Gavrilov & Heuveline, 2003; Richert-Kaźmierska 2013, p. 127). In addition, the rate of ageing of communities in various regions is affected by migration (Strzelecki & Witkowski, 1991, pp. 59-72), including economic emigration (Devictor, 2012).

The demographic crisis, linked to the ageing of the society, currently relates primarily to industrialized, well-developed countries (Population Division of the United Nations, 2013). According to Batini, Callen and McKibben (2006), the developing countries will be using the so-called demographic dividend in the next 20–30 years (Bloom et al., 2001, p. 3). Only in the following decades also this group of countries will experience the ageing of population and the demographic changes will affect their macroeconomic situation, including the level of savings, investment, capital flows and changes in the level of productivity. The World Health Organization (WHO) predicts that the ageing process in these countries will progress much faster than before in the industrialized ones. The published estimates show that, while the increase in the proportion of people aged 65 years and older from 7% to 14% of the total population in France took over 100 years, in Brazil it will take place in just 20 years (National Institute of Aging, National Institute of Health, World Health Organization, 2011).

The ageing of society is a complex process, affecting i.a. the condition and the stability of the public finance sphere, pension schemes or the organization of health and social care. Moreover, it shapes a new reality in the labour market, as well as affects the supply and demand in the market for goods, services and capital (Cutler et al., 1990; Kotowska, 2006, pp. 55-89; Prskawetz et al., 2008, pp. 298-323). An ageing society also means social

¹The Polish Central Statistical Office considers the threshold of old age, i.e. the age beyond which a person belongs to seniors, to be 60 or 65 years (uniformly for men and women or the age of 65 years for men and 60 years for women). The UN studies use uniform age for males and females – 65 years.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

change, including the family structure and intrafamily relationships, education system and the organization of cultural and social life of the elderly (Li et al., 2007).

The analyses related to demographic changes and their consequences are frequently carried out in macroeconomic perspective (Arnott & Chaves, 2012; Clement, 2008). However, the intensity and nature of the effects of ageing are varied regionally (Department of Economic and Social Affairs, United Nations, 2008; Styczyńska & Zaman, 2013). It is primarily the local and regional authorities who are facing new challenges due to the growing share of older people in local and regional communities (Gromig & Trapp, 2006; Ferry & Baker, 2006). One of the key priorities in the decisions and actions taken by them is meeting the needs of the elderly. Błądowski (2002, p. 175) writes about the need to create social policy towards the elderly as a system of activities aimed at people of retirement age and their families. Such actions would be aimed at comprehensive compensation of the capabilities to meet one's own needs, which decrease with age, as well as at the integration with the local community. At the same time, the subject-matter literature emphasizes the need for the development of local and regional comprehensive policies towards ageing, understood more widely than policy aimed exclusively at supporting the elderly (Ilmarinen, 2005, p. 41; Cruz-Saco & Zelenev, 2010; Warner et al., 2010; Błądowski 2002 p. 110; DTT Global Office Creative Studio, 2007).

This article attempts at moving away from the analysis of issues related to ageing in a national perspective, and transferring it to the level of regions. It is shown that the demographic changes in Polish regions have an uneven pace, which means that in each of them the consequences of population ageing may be felt differently. The main objective of the study conducted by the author was to identify regions with the lowest and the highest rate of ageing of the regional community, as well as the regions for which the population data forecasts for the year 2035 are most inferior due to the age structure of their population. The identification of the existing and projected demographic disparities between regions would serve as an inspiration for a debate on the need to create a policy on ageing at regional level, according to the principle of differentiation of the instruments used in it.

Methodology of the research

The changes in the size and age structure of the Polish population observed in the past and projected for the next decade show considerable territorial variation. Therefore, the main objective of the study was to answer the following questions:

- whether there are similarities in the age structure of the population in each of the regions (at present and in the future),
- in which regions the pace of population ageing is highest and where the lowest,
- in which regions the demographic situation is unfavourable economically in the perspective of the next two decades, i.e. where the people of retirement age will constitute the greatest burden on regional communities.

The study consisted of conducting basic and multivariate statistical analysis.

The diagnosis of similarities in age structures of individual provinces was conducted using the multi-dimensional analysis of agglomerates. In order to group the selected provinces, the method of agglomeration with full binding and square Euclidean distance was chosen.

The pace of population ageing was established on the basis of the calculation of the average yearly changes in the age groups and the changes of shares of each of the groups in the total population in the year 2035, compared to the year 2014. In addition, the demographic burden factor², including the demographic burden related to senior citizens³, was calculated for all provinces for the years 2014 and 2035.

To carry out the mentioned above analyses, data from the population forecasts for the years 2008–2035 prepared by the Central Statistical Office (GUS) was used. The population projections for the period 2014–2035 were downloaded from the CSO database, broken down by age and province. The data for the individual provinces were grouped into five age groups (0–17 years, 18–44 years, 45–64 years, 65–79 years and 80 years

² In this case, the demographic burden factor was calculated as the ratio of the number of people at an age when they are economically inactive or passive, i.e. of non-productive age (the number of children aged 0–17 years plus the number of people aged 65 years or more) to the number of people of working age (number of persons aged 18–64 years).

³ The demographic burden factor related to the elderly was in this case calculated as the ratio of the number of persons aged 65 years and more to the number of individuals of working age (number of persons aged 18–64 years).

and more). The adopted distribution allowed for an assessment of the demographic changes in the breakdown meaningful in view of the functioning of local and regional economies, i.e. into the group of individuals of pre-productive age (0-17 years), the so-called *prime age*⁴ (18–44 years), the non-mobile productive age (45–64 years) and retirement age (65 years or more), with distinction of the age group of the aged 80 years or more. The results obtained from such study led to the formulation of proposals related to the present and future demographic situation of Polish regions and the potential economic and social consequences which in relation to such circumstances will have to be faced by the local and regional authorities.

The specificity and the pace of demographic changes in the regions of Poland

Poland has exceeded the threshold of the demographic old age⁵ in 1967 (Główny Urząd Statystyczny, 1968). In the period 1994–2002 the share of the population aged 65 years and over in the general population increased from 11% to 12.6%, and aged 60 years and more from 15.7% to 16.8% (Rządowa Rada Ludnościowa, 2003). According to data from the Central Statistical Office (CSO) in Poland, the population aged 65 years and more in 2014 constitutes 15.3% and in the year 2035 it will constitute 24.5% of the total population (Główny Urząd Statystyczny, 2014) (see Table 1).

Table 1. The age structure of the Polish population in the years 2014 and 2035

Age groups	2014	2035
	[% of total population]	
0–17 years	18.2	15.3
18–44 years	39.8	29.4
45–59/64*	23.6	27.4
60+/65+**	18.4	28.0

* 59 years for women / 64 years for men

** 60 years and more for women and 65 years and more for men

Source: (Główny Urząd Statystyczny, 2014).

⁴ The *prime age* term is not explicitly defined in the subject-matter literature, however it is referred to i.a. by Kautonen (2008) and Boushey (2005, pp. 659–670).

⁵ According to the UN standards, it represents a 7-percent share of persons aged 65 years and over in the general structure of the population.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

According to the predictions of CSO, the population of Poland in the period from 2014 until the year 2035 will decrease by more than 2 million and will amount to 35 993 thousand in the year 2035. During the same period, the median age will rise by about seven years and in the year 2035 will be 47.9. The demographic changes will not, however, take place evenly on a national scale. The current and future demographic situation shows considerable variation in individual regions (see Table 2).

Table 2. The age structure of the population in the provinces of Poland in the years 2014 and 2035

Provinces	Age groups									
	0–17		18–44		45–64		65–79		80 years and more

Source: own elaboration based on (Główny Urząd Statystyczny, 2009).

According to the population projections for the years 2008–2035 in 2014 the regions with the highest share of persons of pre-productive age (0–17 years) in the total population were the pomorskie (19.8%), warmińsko-mazurskie (19.5%) and wielkopolskie (19.3%) provinces. The highest share of people of working age (18–64 years) in the total population was

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

recorded in the opolskie (68.2%), zachodniopomorskie (67,7%) and dolnośląskie (67,7%) provinces. It has to be noted, however, that the highest share of persons of *prime age* in total population was reported in the wielkopolskie (40.8%), małopolskie (40.8%), podkarpackie (40.7%) and pomorskie (40.2%) provinces, while the share of people of the non-mobile productive age was highest in the opolskie (28.5%), śląskie (28.3%) and dolnośląskie (28.1%) provinces. The provinces with the highest share of persons aged over 65 years in the general population are łódzkie (16.9%) and świętokrzyskie (16.6%). According to the same data, in the year 2035 the provinces with the highest share of persons of pre-productive age in the general population will be pomorskie (17.0%), wielkopolskie (16.4%) and warmińsko-mazurskie (16.3%). On the other hand, the provinces with the highest share of post-productive age are opolskie (25.2%) and łódzkie (25.1%). The share of people of *prime age* in the total population will be largest in pomorskie (31.4%), wielkopolskie (31.1%) and małopolskie (31.1%) provinces.

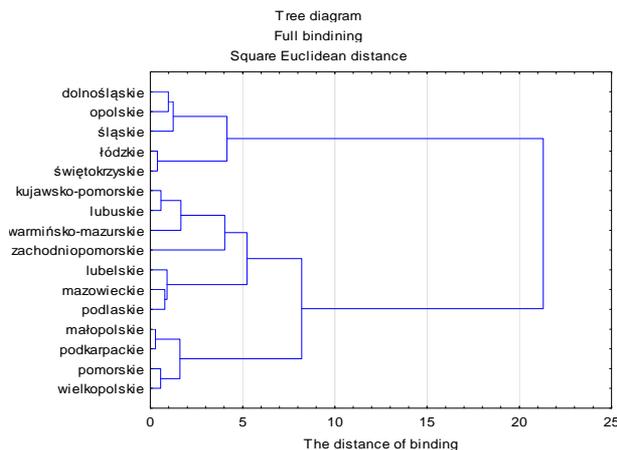

On the basis of the collected data it can be concluded that in 2014 the most favourable demographic situation was present in pomorskie and wielkopolskie provinces. In both these provinces a relatively high proportion of people of pre-productive age and *prime age*, as well as a relatively low share of people of post-productive age (65 years and over) in the total population have been reported at the same time. On the other hand, the opolskie and dolnośląskie provinces, despite having the highest share of people of productive age in the general population, should be considered to be demographically threatened. A significant part of the 18–64 age group are, in fact, people of non-mobile working age, who in subsequent years will be shifting towards the "outbound from the labour market" group and joining the already large group of people of post-productive age. An additional threat in the case of both these provinces is the lowest share of people of pre-productive age in the overall population. The highest share of people of post-productive age in the overall population, including the group of people of old age, has been reported for the łódzkie and świętokrzyskie provinces. It seems that these two provinces were first to begin to feel the effects of an ageing population in Poland.

The verification of the similarity of the structures of the provinces population in 2014 has been conducted based on the multi-dimensional analysis of agglomerates. The tree diagram (see Fig. 1) confirms the above indicated differentiation and allows for dividing the provinces into two main groups: having an adverse demographic structure (dolnośląskie, opolskie, śląskie,

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

świętokrzyskie, łódzkie) and having a moderately favourable demographic structure, with two regions being most favourable as far as demographics is concerned (pomorskie and wielkopolskie).

Figure 1. The similarity of population age structures of the provinces in Poland in the year 2014 – a tree diagram

Source: own work.

According to the forecasts of the Central Statistical Office, the most significant demographic changes in the years 2014–2035 will take place in the opolskie, podkarpackie, podlaskie and warmińsko-mazurskie provinces. And so, in the opolskie province within the next 21 years the share of people aged 18–44 years in the total population will decrease by 10.6 percentage points (p.p.), while the proportion of persons aged 65 years and over will increase by 9.6 p.p. In the warmińsko-mazurskie province the largest decrease of the population of pre-productive age will be observed (by 3.2 p.p.), together with the increase in the number of persons aged 65 and over by more than 9.5 p.p. In the podkarpackie and podlaskie provinces, the share of the persons of *prime age* in the total population will decrease by over 10 p.p., and in addition, a significant decrease in the share of individuals of pre-productive age will occur (by more than 3 percentage points).

The provinces in which the demographic situation will change relatively least, are pomorskie and mazowieckie. In the mazowieckie province, a decrease in the share of individuals of pre-productive age by 2.2 p.p. and the individuals of *prime age* by 9.1 p.p., as well an increase in the proportion of people of old age by 2.8 p.p. will occur. In turn, in the pomorskie

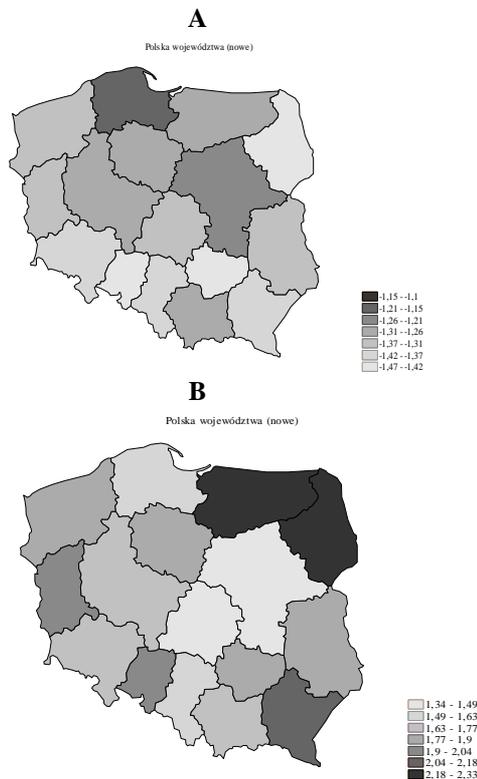

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

province the lowest decrease in the share of individuals of *prime age* (by 8.8 p.p.) and relatively insignificant decrease of the share of people of pre-productive age (by 2.8 p.p.) are projected.

In the years 2014–2035 the largest average yearly changes are projected:

- in the 0–17 age group: in the świętokrzyskie province (-0.89%),
- in the 18–44 age group: in the opolskie province (-1.5%),
- in the 45–64 age group: in the małopolskie province (+0.9%),
- in the 65–79 age group: in the warmińsko-mazurskie province (+2.3%),
- in the 80+ age group: in the lubuskie province (+3.7%).

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

As demonstrated in Figure 2, in years 2014–2035 the greatest rate of adverse changes consisting in reducing the share in of the 18–44 age group in the population of the region will be present in the opolskie, świętokrzyskie and podlaskie provinces. On the other hand, the changes consisting of a rapid increase in the share of the 65–79 age group in the general population will be present in the warmińsko-mazurskie, podlaskie, podkarpackie, opolskie and lubuskie provinces.

The verification of the similarity of the structures of the provinces population in 2035 has been conducted based on the multi-dimensional analysis of agglomerates. The tree diagram (see Fig. 3) confirms that the specificity and pace of the demographic changes projected for the years 2014–2035 will affect the new layout of the demographic similarities among provinces. Once can still talk about the two major groups of provinces being similar to each other in terms of the age structure of the population of the region, although in comparison to the figures for the year 2014 it is more possible to extract four subgroups of provinces similar in terms of their age structure. Among the similar provinces, the most beneficial age structure predicted for the year 2035 should be present in pomorskie, mazowieckie, wielkopolskie and małopolskie.

graphic burden rate related to seniors are considered to be measure of the intensity of a given population's ageing.

In year 2014, the average demographic burden factor calculated as the ratio of the number of people of an age when they are economically inactive or passive, i.e. of non-productive age (the number of children aged 0–17 years plus the number of people aged 65 years or more) to the number of people of working age (number of persons aged 18–64 years), amounted to 0.49 for all the regions, however in the year 2035 it will amount to as much as 0.64. In turn, the demographic burden factor related to seniors, calculated as the ratio of the number of persons aged 65 years and more to the number of persons of working age (the number of persons aged 18–64 years), in the year 2014 averaged 0.22 for all regions, while in the year 2035 it will amount to as much as 0.39 (see Table 3).

Table 3. The demographic burden factor and the demographic burden factor related to seniors in the Polish regions in the years 2014 and 2035

	The demographic burden factor		The demographic burden factor related to seniors	
	2014	2035	2014	2035
dolnośląskie	0.48	0.63	0.23	0.39

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

In all regions the demographic burden factors and demographic burden factors related to seniors in the year 2035 will be higher than in the year 2014. In the case of the demographic burden factor related to seniors, expressly indicating the progress of the ageing of the population, the most unfavourable results are projected for the świętokrzyskie, podlaskie, łódzkie, śląskie, opolskie and lubelskie provinces. In turn, the largest increase in the demographic burden factor related to seniors in the period 2014–2035 is projected to take place in the świętokrzyskie, warmińsko-mazurskie, podlaskie, opolskie and lubuskie provinces.

Conclusions

The results of analyses of the population data presented in the article confirmed that the demographic changes, including the ageing of the society over the next two decades, will concern all Polish provinces. The projected pace and scope of these changes will, however, differ among the provinces.

The provinces in which the rate of adverse changes is expected to be the highest include warmińsko-mazurskie, podlaskie, podkarpackie, opolskie and lubuskie. The greatest changes in the share of young people (0–17 years) in the total population in the years 2014–2035 are projected for the provinces: świętokrzyskie (-0.89%) lubelskie (-0.86%) and warmińsko-mazurskie (-0.85%). In the 65–79 age group, the greatest changes are, in turn, projected in the warmińsko-mazurskie (+2.32%), podlaskie (+2.18%) and podkarpackie (+2.11%) provinces. The świętokrzyskie, podlaskie, łódzkie, śląskie, opolskie and lubelskie provinces also have the least favourable demographic forecasts for the year 2035. In these provinces the share of the population of pre-productive age and prime age in the overall population will decrease significantly over the next two decades, whereas the share of older people (65 years and over) and the demographic burden factor related to seniors will increase.

The application of method of multi-dimensional analysis of agglomerates allowed for distinguishing groups of provinces demographically similar to each other in the years 2014 and 2035. In both cases, two main groups of similar provinces were extracted. A subgroup of provinces with relatively best demographic situation in the years 2014 and 2035 was also discerned. In 2014, the group is made up by the pomorskie and wielkopolskie provinces. In the year 2035, it will comprise the pomorskie, mazowieckie, wielkopolskie and małopolskie provinces.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

The changing demographic situation in individual provinces forces the regional authorities to take appropriate actions aimed at limiting the negative effects of the ageing of the population and adapting the regional policies to new conditions. However, as the pace and scope of the projected changes are varied, the activities of the regional government must be selected according to the current and future demographic situation in the regions.

The article does not provide any research results allowing for the formulation of clear conclusions on the impact of demographic changes on the economic condition of each of the provinces over the next two decades. However, based on the conclusions of the research referred to in the first part of the article, it can be assumed that the most vulnerable are the economies of the regions with the least favourable demographic forecasts. It seems, therefore, that in view of the ageing of the regional communities, the most urgent and intensive actions related to the adaptation of the regional economy, including the infrastructure, labor market organization, social policy etc., should be taken by the governments of the świętokrzyskie, podlaskie, łódzkie, śląskie, opolskie and lubelskie provinces. In turn, the pomorskie, mazowieckie, małopolskie and wielkopolskie provinces (regions with relatively the most favourable demographic forecasts for the year 2035) should focus on activities aimed at ensuring the maintenance of a favourable demographic structure and exploiting the potential inherent in "young" regional communities.

Each of the provinces should work out its own policy in relation to the ageing of the regional community, corresponding to its current and future demographic situation. Without such a policy or in the case of the implementation of a model that fails to match the characteristics of the region, the condition of the regional economy can be threatened and the quality of life in the region, as well as its competitiveness can decrease.

Fiscal Capacity for Euro Area – Towards a Bigger EU Budget?

JEL Classification: *E60; E61; E62; E63*

Keywords: *Fiscal capacity; Fiscal federalism; European Union; Euro area; EU Budget*

Abstract: The European Union has recently implemented one of the biggest reform packages in its history. Developed solutions are designed to (1) strengthen EU's resilience to shocks and (2) improve its shock absorption capabilities. It seems that so far stress was mainly placed on the first objective. Among the reforms, which satisfied the second objective, the European Stability Mechanism (ESM) plays a key role. However, this is not the only solution. The European Union is also developing a fiscal capacity for the euro area.

On the base of a subject literature study, I have developed a model with boundary conditions of fiscal federalism, which then was compared to macroeconomic data for the EU. Results of my findings show that the European Union, and especially the euro area, share a lot of characteristics typical for fiscal federalism. From this point of view, a budget for the euro area seems to be the best form of fiscal capacity. However, it could bring further fragmentation of economic integration process in the EU which probably would not positively contribute towards the stability in the political sphere.

Introduction

Global financial crisis and sovereign debt crisis has launched an unprecedented program of reforms in the European Union. There seem to be no significant disagreements among economists about the causes of crisis, however the proposals for remedies for the EU are not so obvious.

In this work I come forth with the assumption that the European Union is similar in substance to the federation model. As a confirmation of the statement formulated above, I may indicate a number of characteristics which prove that the EU does not differ from countries implementing this model (see: Appendix 1). Presented data show that the European Union is not a unique structure neither by economic development, nor by complexity of administration division. What distinguishes the European Union from other federal countries is national diversity of European society. However, cultural patterns seem to be rather close and one can expect that the tendency will be for them to converge. In my opinion, the biggest problem is a high number of official languages which reduces mobility of labour force within the European Union. This does not bring EU closer to the fulfillment of Optimum Currency Area criteria and the reduces capacity of shock absorption (Tchorek, 2013, pp.187-190). That is why I assume that conducted reforms should lead the European Union to a model of fiscal federalism as a complex solution which could be able to ensure economic stability.

Yet, a lot was done in the monetary sphere of the euro area's economic governance. However, recent economic theory (Rosiak, 2014a, pp.119-121) and practice, put increasing emphasis on the role of fiscal policy. So far, the aim of reforms in the fiscal policy area was mainly to reduce euro area's vulnerability to shocks and strengthen the monetary policy through a fiscal consolidation in member countries. The only permanent solution for shock absorption is European Stability Mechanism (ESM). Functioning of the ESM envisages assistance mainly through loans. Its ability for stabilizing the euro area economy is rather limited (comparing its lending capacity of 500bln euro to whole euro area GDP), therefore one can say, that stabilization functions, like intertemporal stabilization or interregional-insurance, have not been sufficiently provided yet.

The main objective of this paper is to examine whether a new proposal for creating fiscal a capacity for the euro area will fulfill the gap between EU structures and the model of fiscal federalism. Particular emphasis was put on stabilization functions which would help in ensuring sound econom-

ic governance.

Methodology

In my research I have used descriptive approach which, thanks to conducted literature study, allowed me to specify essential features of fiscal federalism. Having collected general features I compared them to the advancement of the EU's pre-crisis integration. Afterwards, I assessed whether recent reforms bring European Union, and especially the euro area, closer to the model of fiscal federalism.

Finally, knowing main drawbacks of conducted reforms in the fiscal federalism context, I gave comments about potential forms of fiscal capacity for the euro area.

Has European Union developed a model of fiscal federalism?

Until recently, literature on fiscal federalism defines only two main boundary conditions of fiscal federalism: presence of a monetary union¹ and a common market (Weingast, 1995). In my paper (Rosiak, 2014b) I introduced main characteristics of this model based on review of literature of fiscal federalism. Those are:

- Multilevel system of governments
- Presence of central and local budgets
- Distinctive features of central budget:
 - a. Size in range from 10% of GDP to 50% of GDP
 - b. Built in functions:
 - i. Redistributive
 - ii. Intertemporal stabilization
 - iii. Interregional insurance
 - c. Taxation assignment:
 - d. Central budget can run deficit while local ones should be balanced
- Presence of transfers and subsidies as a management tools externalities
- Specific allocation of competences

¹ Literature of fiscal federalism usually envisages such a solution for a state not an international organization, as In European Union case. That is why presence of monetary union and the use of common currency is taken by default.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

Features listed above are typical for the model of fiscal federalism. However, it is not necessary to meet all criteria cumulatively. From the fiscal policy perspective, the most important are presence of central and local budgets, features of central budget, presence of transfers and subsidies as management tools for externalities. These features allow for flexible allocation of policies entitlements between central and local budgets.

The role of central budget studied Stiglitz (Stiglitz, 2004) who concluded that provision of national public goods and services as well as provision of stabilization functions should be domain of central budget (see: Fatas, 1998; De Grauwe, 2012; Borzel & Hosli, 2003). For effective resources should be provided. This leads to a question of the proper assignment of taxes to the appropriate level of state administration? This dilemma is also called a tax-assignment problem (see: Tiebout, 1965; Gordon, 1983). Literature on fiscal federalism envisages that, to ensure proper financing, revenues from non-benefit taxes should be collected by the central government, while local ones should collect revenues from benefit taxes as a payment for quality of public goods and services they supply (see: Oates, 1999 or Mueller, 2004). The role of the central government is supreme in relation to local ones. That is why it should have an influence on local decisions thorough system of transfers and subsidies as a main tool for triggering externalities (Boadway, Shah, 2009).

Table 1. presents a detailed look at the advancement of the pre-crisis European integration in the context of fiscal federalism.

As showed above main differences between the model of fiscal federalism and the advancement of pre-crisis European integration are: insufficient size of the central budget, possibility of running deficit by central budget and lack of intertemporal stabilization and interregional insurance functions.

Table 1. Fiscal federalism features in European Union

Feature	Fiscal Federalism	European Union
Multilevel system of governments	Exist	Exist
Presence of transfers and subsidies	Exist	Exist
Size of central budget	At least 5-7% of GDP (optimum 20% - 25%)	≈ 1% of GDP
Budget characteristic	Central: possible deficit Local: balanced	Central: balanced Local: possible deficits

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

Redistribution mechanism	Exist	Exist
Budget functions	Central: redistribution, intertemporal stabilization, interregional insurance Local: allocative	Central: redistribution, interregional insurance (very limited) Local: intertemporal stabilization, allocative
Taxation	Central gov.: non benefit taxes Local gov.: benefit taxes	Central gov.: 0,3% of VAT Local gov.: all types of taxes

Source: based on Rosiak, T. (2014b).

Although the main task of recent reforms was to strengthen the euro area, and not constructing fiscal federalism within euro area, many of new solution bring it closer to the analyzed model. First of all the European Economic Governance Package, the so called sixpack, has made a shift of powers, especially in the area of budgetary procedures, towards European institutions. However Grosse (Grosse, 2013) calls it negative federalism, which builds mainly disciplinary functions without creating new incentives for externalities. The ESM has expanded the function of interregional insurance. Nevertheless the size of the central budget remained the same and stabilization capabilities, however extended, remained rather limited compared to the size of the European Union's economy.

Table 2. EU reforms in the fiscal federalism context

Area of FF	Impact of reforms on EU integration development
Increase in the size of the EU budget	NO
Possibility of running deficit by central budget	NO
Building-in an intertemporal stabilization function	YES – to a limited extent by ESM
Building-in interregional insurance function	NO
Centralization of fiscal policy	YES – to some extent by centralization of some aspects of budgetary procedures
Centralization of economic governance	YES – by better coordination of structural policies through sixpack (European Semester + MIP)

Source: based on Rosiak, T. (2014b).

As shown in Table 2 the main goal for fiscal capacity will be provision of interregional insurance function and enforcement of intertemporal stabilization function. It is worth to mention that full compliance with the fiscal federalism's conditions would be possible only in the case of shift of powers, where local budgets would be balanced and the central one could run a deficit.

Fiscal Capacity for euro area

Fiscal capacity will be the second mechanism, after ESM, with abilities to stabilize the euro area's economy through transfers. All previous solutions (e.g. Sixpack, Twopack, Fiscal Compact and Pact Euro plus) imposed restrictions on national budgetary procedures and thus limited the demand generated by national governments (Heins & de la Porte, 2015, p. 4).

The legitimacy of its creation is motivated by the same rationale that is imposed by the literature of fiscal federalism referring to the functions performed by the federal budget - the ability to stabilize the economy and influence (through transfers) structural reforms conducted in the euro area. More precisely, the ability to stabilize the economy would rely on the incorporation of two functions that fiscal federalism envisioned in the central budget, and that the EU budget did not have: the intertemporal stabilization and interregional-insurance. As was shown in Table 2 ESM provides only intertemporal stabilization function and with a limited capacity.

Necessity to establish a mechanism for the fiscal capacity of the euro area was expressed in two reports from 2012 named 4 Presidents Reports² (*Towards...*, 2012a; *Towards ...*, 2012b). The June Report defined the broad lines of the further integration of the euro area. Lowering euro area's vulnerability to shocks and an improvement of its absorption capabilities was indicated as a main goal. Referring to the integrated budgetary framework, clearly identified and named was the need to build a fiscal union that would ensure the stability and security of the euro area. Authors consider, also in the medium term, the possibility of joint debt issuance, which also contributes to a further fiscal integration and the need to redefine the role of the central budget in new institutional and economic realities. At the end, there is expressed the need for further development of a road map that would lead to the creation of a genuine Economic and Monetary Union.

The December Report goes deeper into the topics raised in the June Report, focusing mainly on aspects of coordination of budgetary policies and joint economic governance. It has also developed a general framework of implementation of the vision from the first report. It has been divided into 3 stages. The goal of the first one, planned from the end of the year 2012 and for the year 2013, was to found the fiscal stability of the euro area and to

² These two Reports were developed by President of the European Council – Herman Van Rompuy with close collaboration with: José Manuel Barroso, President of the European Commission Jean-Claude Juncker, President of the Eurogroup Mario Draghi, President of the European Central Bank.

18-19 June 2015, Economics and Finance**

break down the relationship between the liquidity of banks and public debt. The second, planned for the years 2013-2014, assumed the implementation of integrated financial framework and further support of structural reforms. The third stage, covering the period after 2014, is the most important one from the point of potential fiscal federalism in the European Union, because it envisages improvement in flexibility of the EMU's functioning by creating a central mechanism for shock absorption.

All monetary unions have their fiscal capacity mechanisms (*Towards...*, 2012b, p.9). Vulnerability to shocks and the lack of effective mechanisms of shock absorption seems to confirm the need to implement such an instrument also within the EMU. In the euro area the additional function that would implement such a mechanism would be a promotion (through various financial incentives) structural reforms which could contribute to higher economic growth in the future. However, form of the fiscal capacity has not been clarified yet. The December Report only sets out, that the contribution and the payment from the fiscal capacity will match the position of the member country in its economic cycle. Vetter (Vetter, 2013, p.1) proposed 4 possible forms of fiscal capacity:

1. A common budget,
2. An insurance mechanism against strong cyclical fluctuations,
3. A common unemployment insurance scheme,
4. An equalization scheme for interest burdens.

The idea of separate euro area budget is not new and quite popular among economists studying European Union's problems (see: Verdun, 2015). Implementation of the fiscal capacity in the form of a separate budget for the euro area (1) would require an indication of its revenue sources. From a few concepts of revenue sources one may indicate: membership fees proportional to the size of the member country's economy or in form of taxation. There are two possible ways of tax collection: by introducing a new tax e.g. financial transaction tax (see: or as part of the nationally collected tax e.g. part of an income from collected VAT. Each approach has its drawbacks. The new membership fee or a portion of VAT revenues will adversely affect the condition of tight local budgets. The financial transaction tax would require fairly complex algorithms for receiving this revenue from various countries (the proportion of the financial markets in different countries relative to GDP vary considerably). No matter the source, economists estimate that euro area budget would need approximately 2% of GDP in revenues (see: Wolff, G., 2012) .

Budget form of fiscal capacity would incorporate interregional insur-

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

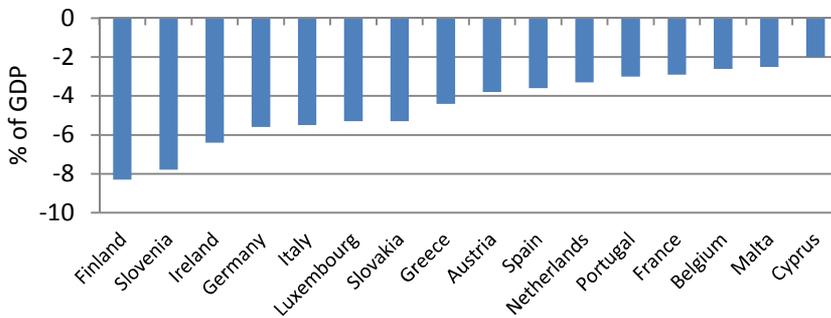

ance function. Another advantage of this solution would be the possibility to install automatic stabilizers, which, on the one hand, allow for a quick response to economic fluctuations (automatism) and the support for the counter-cyclical fiscal policy stance on the other. From the point of view of the European integration process, creation of a new, separate budget could be considered a step back (the current shape of the central budget of the European Union is in fact the result of the consolidation of budgets of European Communities). Other reforms such as the Fiscal Compact or the Euro Plus Pact are intergovernmental agreements, so as for now they can be perceived as a desintegrating mechanisms as well or as a part of bigger disintegration process within European Union (Vollaard, 2014, p.4). However, documents include a commitment to incorporate them into the EU law. On the other hand, fears about the collapse of the euro area seem to be exaggerated. The EU citizens are becoming more utilitarian in their understanding of the euro and its institutional framework, so they rather would not vote for withdrawal from the euro area or the European Union (see: Ioannou et al., 2015, p.169)

Insurance mechanism against strong cyclical fluctuations (2) could be financed from contributions made by the member states in time of economic growth. Payments would be realized if a negative shock occurred. The problem, which is associated with this solution is the selection of an appropriate methodology to determine the moments of mobilizing resources and their total amount. They should, on the one hand, correspond best to the realities of the euro zone and be acceptable to all 19 states on the other. Vetter (Vetter, 2013) suggested that assistance should be provided in a country where the negative output gap will reach 2% of GDP. Country experiencing such problems could then receive a payment from the insurance mechanism in the amount of e.g. 25% of the shortfall.

The most significant disadvantage of this solution is the need to develop additional scenarios for years in which almost all euro area countries fell into recession. This occurred in 2009, when all euro area countries fell into recession, as well as in 2012 and 2013, when nearly half of them had negative economic growth.

18-19 June 2015, Economics and Finance**

It is possible that in such a situation, when over half of member countries need assistance, financial capabilities of the insurance mechanism would not be sufficient, as the number of contributor-countries would be too low.

The advantage of the common unemployment insurance scheme (3) is its automatism. It can be set up in a way that enables launching the stimulus upon exceeding a certain level of unemployment in the region, and not necessarily in a whole member country. That is why assistance would be given directly where it is needed the most and resources of the unemployment insurance scheme are managed most reasonably. The problem, which arises, is that most often companies do not lay off its employees in the first place, when economy is affected by the negative shock. It is therefore possible that the aid flowing from such a scheme would stimulate the economy too late, that is, when the worst consequences are already being felt – employment reduction are made and increased number of people are unemployed.

The last possible form of fiscal capacity - interest equalization scheme of government bonds (4) would have to eliminate unjustified differences in interest rates on government bonds of euro area countries. This would be provided through a specially established European agency. An explanation for setting an interest equalization scheme of government bonds are the consequences of the recent crisis, when interest rates on bonds of euro area countries have varied considerably. As a result of this situation, some countries have suffered significant losses (i.a. Greece, Portugal, Spain), some have gained (e.g. Germany, the Netherlands). What is interesting, countries like Belgium, that theoretically should be in the group of losers, have also benefited.

Interest equalization scheme of government bonds would give member states a chance to issue some portion of the debt (e.g. 10%) by the European agency. This would significantly increase liquidity of government bonds market in Europe and lower interest rates for countries in the process of debt refinancing. The program could also provide a larger tranche for a country, which will experience problems with the debt issuance (when its cost could increase considerably). Other, similar solution envisages issuing, agency collateralized debt obligations (CDO) with varying degrees of risk covered by the purchase of approx. 60% of the bonds issued by the euro area countries, by a special European.

Both of these approaches can solve the problem with excessive fluctuations in bonds' interest rates and help to stabilize public debt borrowing

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

costs. However, they are based on the assumption that each crisis has to negatively affect borrowing costs while for example German economy being in recession in 2009 did not suffer from higher costs of borrowing. In that case assistance would not have been provided although stimulus action, especially in certain regions, would probably help their economies to recover.

Conclusions

European Union shares a lot of characteristics with the model of fiscal federalism. However it does not benefit fully from all profits, which can be provided. This is mainly because of insufficient size of central budget, which is not equipped with functions that could help in stabilizing an output in the euro area i.e. function of intertemporal stabilization and interregional insurance.

European leaders took actions to strengthen the European Union and especially the euro area. In general conducted reforms can be classified as those which have preventive and reactive nature. Of rather preventive nature are: Sixpac, Twopack, Fiscal Compact and The Euro Plus Pact. Among existing solutions of reactive nature there is only ESM. However its potential impact on the whole euro area's economy is rather limited. That is why ESM is not the only mechanism for stabilizing European economy and The President of European Council – Herman van Rompuy launched the project which purpose is to create a fiscal capacity.

No matter which solution will be implemented EU authorities should put maximum effort to ensure:

1. Automatism – to avoid the temptation of discretionary decision making
2. Minimum lags – fiscal capacity should provide assistance when it is the most needed (e.g. before wave of redundancies happen)
3. Maximum financial impact on the economy - usually a fiscal multiplier is the greatest at the beginning of a crisis / recession (this is actually a follow-up of point 2)
4. Capacity - the solution should solve not only the economic problems of small countries or a small group of countries.

Taking into account stabilization functions which fiscal federalism provides through central budget, separate budget for euro area seems to be the best form of fiscal capacity. However creating a separate budget for the euro area can bring significant negative consequences for the European integration process as a whole.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

Giving comments about possible forms of fiscal capacity I indicated problem of revenue sources only in the case of the budget. In fact, concerning high ratio of debt in most euro area countries, one may expect that financing for other solutions will be the issue as well. This is why skepticism about fast launching of fiscal capacity for euro area seems to be justified.

Contemporary Nature of Stock Exchange from the Perspective of Demutualization Process

JEL Classification: *G15; L21; L31*

Keywords: *demutualization; stock exchange; company; government; society*

Abstract: As a part of the demutualization process, stock exchanges are transformed from a traditional membership (mutual) structure into an entrepreneurial structure. Changes in the legal and organizational structure take place and they diversify their activities in order to meet the market needs. Statistical data confirm that two thirds of stock exchanges are of for-profit type and as many as 40% are listed exchanges. But we cannot conclude that stock exchanges, after the demutualization process and going public, operate more efficiently than the stock exchanges not subjected to these processes. On the other hand, analyzing the structure of the products on stock exchanges, it may be noticed that most of the exchanges have a diversified range of services.

However, it should be emphasized that the activity of stock exchanges is partly seen as a public good even if they are managed by private people. But the efficiency increase of stock exchanges does not necessarily translate into the quality increase of their socio-economic functions and short-term pursuit for profits may pose a threat to the functioning of the economy and society.

Introduction

In the classical terms, stock exchange is defined as “any organization, association, or group of people, whether incorporated or unincorporated, which constitutes, maintains, or provides a market place or facilities for bringing together purchasers and sellers of securities or for otherwise performing with respect to securities the functions commonly performed by a stock exchange as that term is generally understood, and includes the market place and the market facilities maintained by such exchange” [Di Noia, 1999, p. 17, following: American Securities Exchange Act]. Stock exchange is aimed at providing centralization for trading securities as well as determines the flow of information, disseminating and triggering competition among the participants of stock exchange.

Historically, stock exchanges were institutions of non-profit type, organized as a cooperative or functioning as state institutions. Their activity was carried out in the interest of public activity through the implementation of macro-economic functions: allocation, valuation of securities and control [Kulpaka, 2007, p. 51]. As a result of electronization of stock trade and transformation of the organizational and legal form of stock exchanges, so-called demutualization, there has been a change in the rules of their functioning. At present most stock exchanges operate as commercial enterprises, directed towards profits. In the view of the described phenomena the problem appears concerning the essence of modern stock exchanges and threats connected with a change of their organizational and legal structures.

Methodology of the research

The purpose of the article is to analyze the changes in the functioning of stock exchanges due to the organizational and legal form and the consequences of these changes. The research hypothesis was stated that the demutualization processes determined changes in the rules of functioning of stock exchanges and created threats from the point of view of socio-economic functions.

In order to verify the hypothesis, we use literature studies that allowed recognizing the key theoretical issues and presenting the essence of the phenomenon of demutualization as well as threats associated with the transformation processes of the legal form of stock exchanges. In the article we use the cause and effect analysis for the presentation of the transformation process of the organizational-legal form of stock exchanges and the result-

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

ing effects, along with a logical analysis consisting in the search for a logical relationship between the causes and consequences of these changes. In addition, based on the data published by the World Federation of Exchanges (WFE), the analysis of statistical data on stock exchanges and their financial results was performed. The data refer to 57 stock exchanges - members of WFE.

**Changes in the ownership structure of stock
exchanges - demutualization processes**

According to the Anglo-Saxon model, the traditional organizational structure of stock exchange is a cooperative established by the members of stock exchange. In contrast, the continental (European) model is a stock exchange operating on the basis of the legal act, under the State control [Ramos, 2003, p. 13]. In the cooperative structure usually the members are financial institutions who are intermediaries in securities trading representing the interests of investors (brokers) or their own (dealers). This form of exchange is a result of the fact that the capital market on which an efficient trading of securities should take place must be located in a very specific place, functioning at fixed times, according to the established rules of reporting and implementation of contracts and with a guarantee of the settlement of transactions (delivering cash and securities). In order to meet the conditions presented and to prevent an overflow on the trading floor, such brokers should have been selected who represented the interests of everyone concerned by the trade. Rationing of the access to the exchange was conducted through the sale of "places", that is by membership fees - high initial and lower annual fees [Steil, 2002, p. 2]. Nevertheless, non-members wishing to use the opportunities offered by the concentration of capital in one place had to pay the members of stock exchanges for representing their interests. In this way the members of the stock exchange have become the intermediaries (brokers) for transactions realized by the investors.

The technological factors and liberalization of the regulations concerning the capital flow and circulation forced changes in the form of operation of stock exchanges and thus determined the demutualization processes. The open outcry system used previously was replaced with the electronic trade in which the investors make investments in securities on their own [Gorham, 2011, p. 3]. The computerization of stock trading eliminated the intermediary role of brokers which was connected with the process of disintermediation. In turn, the liberalization of regulations on the capital move-

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

ment and trade led to a gradual expansion of possibilities and at present, in some regions even to freedom in the activity of investment institution.

Demutualization is a process of moving away from the traditional cooperative (mutual) structure of stock exchanges [Steil, 2002, p. 6]. The basis of demutualization is the separation of property rights and membership of stock exchange. In this process the owners become third parties who are not the members of the stock exchange. It should be emphasized that a full demutualization of stock exchange is a complex process. One cannot specify a single event that causes an immediate demutualization. Generally, this process consists of four steps [Jacquillat, 2006, p. 155]. The first stage is considered as organizing the exchange in a cooperative form. The second stage is the transformation process of stock exchanges into for-profit organizations but the members of stock exchange are its owners and supervisors. The next step is to change the legal and organizational structure for the joint-stock company in which the owners of stock exchange, apart from its members, are the external entities. The fourth step is to issue its own shares. At this stage the owners are the individual stock market investors and institutional investors. The shareholders become more diffused.

Literature mentions two basic reasons for demutualization. The basic reason is to reduce the control of exchange members (especially local, national ones) as the strategic owners. Stock exchanges operating in a competitive financial market, in order to be competitive, must reduce the costs for the issuers of securities and increase the investment portfolios for the investors. In contrast, the members of stock exchanges leading to maximization of their own profits from brokering do not always care about the competitiveness improvement of exchanges. The main justification is the belief that the private structure enables a faster response to new challenges in the environment [Jacquillat, 2006, p. 159].

Another reason for demutualization is raising capital - by selling shares - necessary for expansion and investment in technology. Studies show that the increase in capital in relation to demutualization is the secondary purpose or it may be no purpose at all [Steil, 2002, p. 6]. Most stock exchanges which conducted demutualization had no urgent need to obtain new capital. Moreover, in case of the lack of capital its increase may occur from membership payments without a necessity to involve the external owners.

Demutualization implies a departure from the traditional cooperative structure of stock exchanges. At the same time the exchanges acquire new non-members owners of exchange. Due to a different share of external owners the exchanges may be varied. The World Federation of Exchange

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

proposed the classification of exchanges comprising of five categories. The first category are private, limited companies. These are stock exchanges registered as private companies, generally with a paid up share capital. In these exchanges the intermediaries are usually the sole owners of the exchange and their ownership, intermediations rights and activities are strongly linked. The second category are private, limited companies after demutualization, but not listed. The demutualization of exchange is a process by which a not-profit member-owner organization is transformed into a for-profit shareholder corporation. Ownership is more open. The third category is the publicly listed exchanges. The stock exchange goes public when its shares are listed on an exchange and are freely negotiable. The fourth category includes exchanges registered as associations or mutuals. These member cooperatives generally have no share capital. Access to membership is restricted. The last category regroups exchanges with "other" legal status. The example are exchanges which have a government or semi-government agency structure and belong to the state [Devai & Naacke, 2012, p. 38].

**Characteristics of the functioning of stock exchanges
after the demutualization process**

Changing the organization of stock exchanges causes that the exchanges are more of an entrepreneurial example than a mutualized management structure. Assuming the formula of companies, their purpose of activities becomes to maximize profits. The group of stakeholders who are interested in the financial result generated by the exchanges are not members yet but the new owners-shareholders.

Stock exchanges after the demutualization process take a form of commercial business entities engaged in service activities. They provide services in the areas: issuers servicing, financial instruments trading (on cash and derivatives market), information dissemination and other which may include clearing and settlement services, sales of software for trade analysis, organizing trainings etc. [Gorczyńska, 2012, p. 33-35]. Each of the presented areas generates revenues and costs. Exchanges that want to be leaders must function effectively, diversifying their activity among the areas that provide the greatest opportunities for growth and thus revenues, at the same time resigning from providing the services that are not competitive. Therefore, they open new trading markets, e.g. for innovative small and medium-sized businesses, create new products as well as they acquire the functions from a value chain that were previously served by separate

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

institutions. In addition, the exchanges target their efforts on using even newer and more efficient information technology and telecommunications as well as selling new products. These activities are aimed at attracting the largest possible number of clients - issuers and investors, and simultaneously optimizing costs.

Stock exchanges expand their business within the frames of the internal development or the external development - consolidation. Product diversification in the external development takes a form of horizontal consolidation. Exchanges of similar profile of activity (e.g. exchanges of derivatives) may consolidate, as exemplified by the CME Group formed by the merger of exchanges: the Chicago Mercantile Exchange (CME), Chicago Board of Trade (CBOT), the New York Mercantile Exchange (NYMEX), COMEX and the Kansas City Board of Trade. The exchanges of different product profiles may also consolidate, such as derivatives exchanges and cash exchanges, e.g. Deutsche Börse Group, in which Deutsche Börse merged with Eurex. Today, the mergers between the exchanges in various countries dominate, resulting in the formation of transnational exchanges (e.g. NYSE Euronext, NASDAQ OMX). This leads to the phenomenon known as denationalization of international stock exchanges or international integration of exchanges [Chesini, 2007, p. 151].

Stock exchanges also "absorb" the activity that has not been included in the value chain so far. They do this by vertical mergers. This type of consolidation usually involves a combination of stock exchanges (quotation system, trading) with clearing and depository institutions, i.e. post-trade integration. Vertical integration among the stock exchange, clearing and deposit chamber took place in the Deutsche Börse (DB), Amsterdam and Brussels.

Both, horizontal and vertical consolidation are aimed at costs reduction, but also at attracting more and more business entities involved in the stock market transactions, therefore at increasing the competitiveness of the merging exchanges.

**Threats associated with the activities of stock exchanges after the
demutualization processes - outline of the problem**

Demutualization leads to the fundamental changes in the management and ownership of stock exchanges. In the area of property it is connected with an increasing role of external owners, including the institutional ones from a financial sphere. These investors are associated with the so-called

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

impatient capital, searching for possibilities to obtain extraordinary profits in the short term [Ratajczak, 2012, p. 283]. The growing relevance of the owners presented and changes in the structure of exchanges aimed at profit may be connected with threats in the execution of socio-economic functions.

Generally, within the frames of the cash market a classic function of exchanges takes place - allocation, in which capital is transformed between its holders and those who notify a demand for it. After the demutualization processes, exchanges target their actions at the short-term, profitable business spheres. This is the sphere of derivatives market. Derivatives, in its original essence, were supposed to hedge risks (including currency exchange risk) of financial transactions carried out by the operators internationally, however, they have become a form of rapid, profitable but also risky earnings. Analyzing the global volume of options and (single) futures trading calculated using the amount of contracts in million in the years 1996-2010, it increased more than 10-fold, reaching a record of 436,785,502 option contracts in the year 2007 and 1,058,862,743 futures contracts. [<http://www.world-exchanges.org/statistics/annual/derivative-markets/derivatives>]. Consequently, within the frames of the presented phenomena, "(...) more and more resources are invested in financial activity rather than the production of goods and services, that generate high private returns disproportionate to its social utility" [Tobin 1984, p. 14].

The activities of stock exchanges focused on short-term earnings can be connected with a danger of underfunding the countries or sectors of the economy. The owners from the financial sphere often treat their participation in the real economy as one of periodic and alternative forms of capital investment but not as a real long-term commitment in the ownership with the intention of developing the particular organization [Ratajczak, 2012, p. 283]. Therefore, as a result of tendency towards earning money quickly, instead of allocating capital in the development of industries in the economy, the capital will go to the most profitable projects which are not necessarily relevant for the economy development of the particular country. In an international scale this phenomenon may lead to capital outflow from the countries perceived as weak from point of view of investments (short-term ones). Due to investment opportunity, and therefore the allocation of capital globally, an excessive concentration of capital inflow may occur in some countries and a lack of access to it in the other ones. Moreover, in the case of a large inflow of foreign capital to the relatively illiquid financial mar-

kets may lead to losing the influence in the domestic markets in these countries. [Kowalak, 2006, p. 49].

The dynamic development of derivatives markets is a threat to the individual investors too. Derivatives are profitable in the short term, but they are also risky speculative instruments. Their multi-level structure concerning profits depending on the price of another asset has blurred the picture of risk [Gorczyńska, 2011, p. 83]. Their complexity is so high that even those who, on behalf of other market participants should assess the risk involved, such as rating agencies, are also the victims of asymmetric information. This has resulted in violation of the fundamental rules of trust between sellers (e.g. new financial products) and buyers. Currently, the old Latin maxim *caveat emptor* ("let the buyer beware") gains a new special significance [Freeman, 2010 p. 165].

The development of the derivatives markets may also lead to pathological phenomena concerning a long-term investment. In general, for cash equities there is a relationship between the ownership and direct realization of managerial functions or the ownership by ceding management functions to the hired managers. In case of derivatives, the ownership without the awareness of being a co-owner is possible as well as the ownership which generally is not accompanied by any rights or obligations. The owner of derivatives may even be interested in bankruptcy of the entity whose activity is the source of derivative creation, or more often may be interested in a significant variability of the events affecting valuation of the derivatives held and in a possibility of speculative rent collection more than in stable development [Wigan, 2009, p. 165].

The pursuit for short-term profits may lead to the actions that threaten the security of trading on the stock market. Competition among the exchanges and between exchanges and OTC markets (ATS-s) may result in lowering the requirements for listed securities or business entities (institutional) accepted for direct trade. Indeed, stock exchanges, in order to attract new investors and increase turnover, are able to minimize the regulations defining access to the stock market. This was the case in the US where some exchanges such as the NYSE hindered trading of securities listed outside the stock exchanges, NASDAQ market did not impose such restrictions on its participants [Stoll, 2008, p. 17].

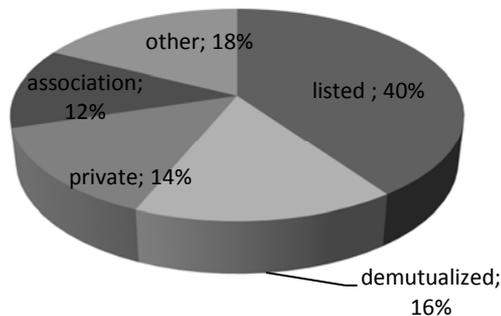

The contemporary industry of stock exchanges is characterized by competition. It is obvious that in a long-term perspective the ineffective exchanges will lose their market share. It should be clear that the stock exchange cannot only be seen as a commercial institution focused on increas-

ing its efficiency. Stock exchanges are business entities providing "specific goods". According to the traditional approach, these services are public goods even if the exchange is private [Di Noia, 1999, p. 18-19]. Through the services of trading, issuing, listing, they execute the function of allocation, valuation of securities and control - functions of socio-economic character.

Characteristics of the activity of stock exchanges by organizational and legal form in numbers

In order to verify the considerations presented in the theoretical part, data analysis was performed on the selected aspects of the functioning of stock exchanges. Firstly, we examined the extent to which the stock markets are exposed to the demutualization processes. For this purpose we analyzed the quantity and structure of exchanges according to their organizational and legal form in figure 1.

Figure 1. Breakdown exchanges by legal status (members of the World Federation of Exchange) in 2012

Source: R. Devai & G Naacke (2012, p. 8).

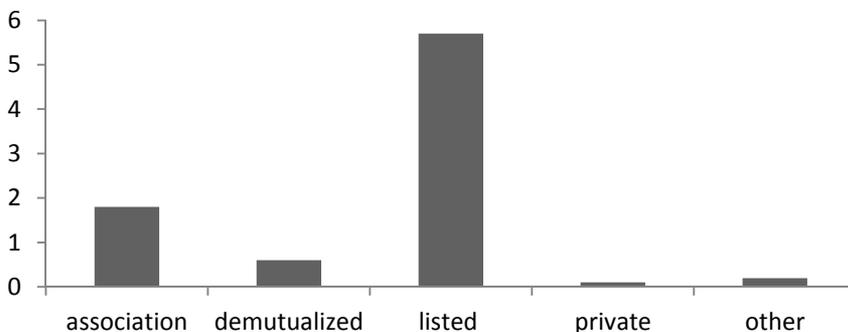

The largest group by legal form are listed exchanges (23 stock exchanges), that is 40%. They are dominated by NYSE Euronext, NASDAQ OMX Group, CME Group and Deutsche Boerse, which represented 57% of total revenues of this group in the year 2012. The next part (18%) are the stock exchanges of "other" legal status. They are represented by, among others, Abu Dhabi Securities Exchange, Moscow Exchange, The Egyptian Ex-

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

change. 16% are demutualized stock exchanges (9 exchanges). The demutualized group is dominated by China Financial Futures Exchange, Korea Exchange, National Stock Exchange of India and Taiwan Stock Exchange that accounted for 80% of the revenues. The private exchanges consist of 8 exchanges (14% of all exchanges). They are dominated by SIX Swiss Exchange and Taiwan Futures Exchange. The smallest group comprises of association/mutual exchanges (7 members, 12% of all exchanges). It is represented by 5 exchanges in Mainland China (Dalian Commodity Exchange, Shanghai Stock Exchange, Shanghai Future Exchange, Shenzhen Stock Exchange and Zhengzhou Commodity Exchange) that amounted to 99% of revenues of associations in the year 2012. All in all, a dominant part of stock exchanges has been exposed to the demutualization process. 74% of exchanges are for-profit, but only 26% are not-for-profit organizations. As many as 40% of are listed exchanges - exchanges that are on the highest stage of demutualization.

When analyzing the stock exchanges by legal status it is worth comparing the economic and financial results of each form of exchanges. It should be noted that the financial results, in addition to the legal form, are influenced by other factors. The comparison was made according to annual net income and return on equity capital (ROE) of exchanges by legal status.

Figure 2. Net income of stock exchanges by legal status in 2012 (USD billion)

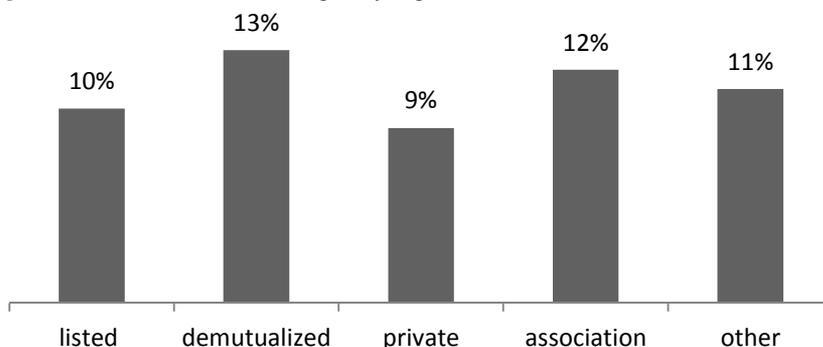

Source: R. Devai & G Naacke (2012, p. 18).

In accordance with figure 2 presented, the largest net income is generated by the listed exchanges. In 2012 it amounted to approx. 6 billion USD. The next group of exchanges (in terms of net income) were association exchanges (less than 2 billion USD). Other exchanges generated net income of less than 1 billion USD. Such high net income generated by the listed

exchanges is connected with the fact that these exchanges constitute the largest percentage of operating exchanges and have the largest equity (of about 70 billion USD). Furthermore, within the frames of these exchanges the world's largest stock exchanges operate as: NYSE Euronext, NASDAQ OMX Group, CME Group and Deutsche Boerse. The global distribution of costs and revenues among each legal status reflects the weight of listed Exchange, which accounted for 80% of revenues in 2012 (in comparison with 40% of the membership).

Apart from net income, it is worth looking at other financial data. Figure 3 shows ROE (return on equity capital) of stock exchanges by legal status.

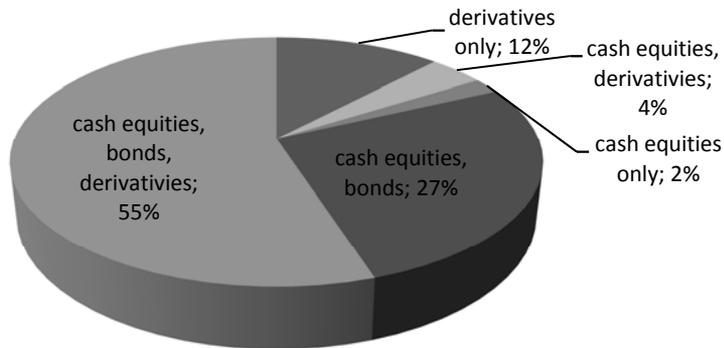

Figure 3. ROE of stock exchanges by legal status in 2012

Source: R. Devai & G Naacke (2012, p. 25).

When analyzing ROE for the individual exchanges we cannot see any significant differences in the level of this indicator. It is at a comparable level of approx. 10% for each type of exchange, with the highest 13% for the demutualized exchanges. The listed exchanges received one of the lowest ROE although their net income was the highest. This level of indicator is linked to the fact that these exchanges have the highest level of equity capital. The fact may be interesting that there are no significant differences in ROE between the non-profit and for-profit exchanges. As a matter of fact, the non-profit exchanges received even higher ROE (11%) than the for-profit ones (9%) [R. Dévai & G Naacke, 2012, p. 25]. Thus, the presented data do not allow drawing the conclusion that the stock exchanges after the demutualization process and the issuance of own shares operates more efficiently than the stock market not exposed to these processes.

Figure 4. Breakdown of exchanges by products in 2012

Source: R. Devai & G Naacke (2012, p. 10).

Apart from the financial data we should also examine the structure of products offered by stock exchanges. Among the analyzed members of the WFE (figure 4), most stock markets offer a wide range of products. 55% of the stock exchanges offered three classes of assets, i.e. cash equities, bonds, derivatives; 27% within the frames of classes of assets: cash equities, bonds and 4% within cash equities and derivatives. Only 14% were stock exchanges with one product that offer derivatives only, and only 2% cash equities.

Stock exchanges, in addition to product diversification, expand their range of services. Beside the classic services of listing and trading they run a post-trade activity. 77% out of all the members of the WFE are the exchanges performing the functions of clearing, settlement and depository services. The remaining 23% are non-active exchanges in the post-trade services but have a stake in the company providing the post-trade services. The example is The Central Counterparty Austria (CCP.A) which offers all clearing services for the Wiener Boerse (Wiener Boerse is with OEKB - Oesterreichische Kontrollbank), the joint-owners of CCP.A. Also Johannesburg Stock Exchange owns 44.55% of the Central Securities Depository.

Consequently, the stock exchanges, as a result of the process of demutualization and electronicisation of trading, transform from the institutions offering cash market products into organizations offering a wide range of products and services beyond the classic listing and trading.

To sum up, the analyzed statistical data confirm that a dominant part (two-thirds) of stock exchanges was exposed to demutualization and as many as 40% ones are listed exchanges - the exchanges on the highest stage

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

of demutualization. It cannot be concluded that the exchanges after the demutualization process and the issuance of own shares operate more efficiently than the stock exchanges not exposed to these processes. In turn, analyzing the product structure of stock exchanges one can see that most of the exchanges have a diversified range of services.

Conclusions

The conducted analysis created the basis for verification of the hypothesis that the demutualization processes determined changes in the rules of functioning of stock exchanges as well as created threats from point of view of socio-economic functions.

Stock exchanges make changes in the legal and organizational structure as well as diversify their activities in order to meet the market needs. It should be noted, however, that the activity of stock exchanges is partly seen as a public good even if they are managed by private people. In contrast, the increase in the efficiency of stock markets does not necessarily translate into the increase of quality of their socio-economic functions, and a short-term pursuit for profits may pose threats to the functioning of economy and society. General social problems are usually solved by the system of public supervision over the stock market [D. Switzer 2013, p. 104]. Therefore, the role of the state is important so that within the frames of creating the structures of stock exchanges there should be a system of public supervision established paying attention to the interests of society and economy.

Comparative Analysis of Economic Efficiency of Polish and German Listed Companies*

JEL Classification: *G32*

Keywords: *efficiency; measure of efficiency; DEA; Polish and German joint-stock companies*

Abstract: The main subject of theoretical-empirical study presented in this paper is economic efficiency of companies listed on the Polish and German capital market. The discussed research problem was investigated in the form of a comparative analysis and realized in two parts. The discussion presented in the first part depicts mainly theoretical reflections on the essence and assessment measures of companies' economic efficiency. The second part presents the results of a comparative empirical research on economic efficiency of the companies listed on the Warsaw Stock Exchange and included in the WIG30 index as well as the companies listed on the Frankfurt Stock Exchange, which belong to the DAX index. The research period comprises years between 2004-2013. A comparative analysis of economic efficiency of the companies was conducted using a traditional ratio analysis and the nonparametric DEA method. The results of the empirical research confirm that German companies achieved significantly higher values of basic economic categories in the analysed decade, financial results in particular; however, their generated profits did not reflect in higher values of profitability ratios. Polish companies performed much better as they also showed higher efficiency from the DEA's point of view.

* The publication is co-financed from the funds of donations for the projects fostering the development of young scientists and doctoral students.

Introduction

Conducting a comparative research on the problems of economic efficiency of the companies listed on the European stock exchanges is a natural consequence of adopted and realized micro- and macroeconomic objectives of the EU economic development. One of them is the growth of economic efficiency of public limited companies. It translates into the economic growth of national economies and improvement of life of societies.

The problem also concerns the companies listed on the Polish trading floor compared to the companies listed in stock exchange indexes in developed countries including Germany. While analyzing data from the International Monetary Fund which concern economic growth, it must be noted that in the recent years the Polish economy has achieved, and according to the forecast, it will still achieve much higher values of the real GDP than the German economy¹.

Economic efficiency plays a leading role in shaping of the investment potential of public limited companies listed on the capital market in a given country. The potential is diversified and it seems that German companies, which function in a developed market, will have a high development level of production factors, in particular, much higher values of wealth and capital in comparison with Polish enterprises. On the other hand, it seems likely that they do not exploit production and service reserves significantly, which may result in a lower level of economic efficiency in German listed companies as compared to Polish entities.

The main aim of the study is to determine the level and character of spatial diversification of economic efficiency in the companies listed on the Warsaw Stock Exchange and Frankfurter Wertpapierbörse. In order to achieve this objective a specific research hypothesis was formulated and it stated that in economic practice there are significant differences in the level of economic efficiency of the analysed Polish and German public limited companies, and they mainly concern return on total assets.

¹ According to the IMF data, the real GDP in 2013 amounted to 1.6 in Poland, whereas in Germany 0.5. Moreover, the IMF forecasts show that between 2014-2015 the economic growth rate will respectively amount to: for Poland 3.1 and 3.3, and for Germany 1.7 and 1.6.

Methodology of the research

The conducted empirical research refers to the companies listed on the Warsaw Stock Exchange and included in the WIG30 index as well as the companies listed on the Frankfurt Stock Exchange (germ. Frankfurter Wertpapierbörse – FWB)², which belong to the DAX index. The analysis comprised financial statements of 60 companies classified for both indexes on 20.11.2014. In order to meet the objective of the study the author decided to concentrate on a ten-year research period i.e. years between 2004-2013. Empirical data was obtained from the EMIS (Emerging Markets Information Services) database, stock market bulletins, Polish and German stock exchanges' websites as well as the websites of the analysed companies.

The analysed research problem is realised in two parts. Discussion in the first part includes the assessment of the companies' efficiency based on a traditional ratio analysis using accounting measures. It was assumed that two analytical dimensions can be included in the applied system of the efficiency assessment. These are the following:

- a) an absolute dimension i.e. accounting balance sheet and result categories, and
- b) a relative dimension (return ratios)³.

The other dimension of company's efficiency assessment allows to use standard formulas of return on sales ratio (ROS), return on equity ratio (ROE) as well as return on total assets ratio (ROTA), which are respectively a relation between net profit to return on sales, equity and total assets. For the sake of comparison of stream data with balance sheet data while constructing last two ratios, a methodical solution that was used, accepted a balance sheet value of equity and total assets as an average state in a given period:

² Frankfurter Wertpapierbörse (FWB) is the largest of seven stock exchanges in Germany and one of the most important financial centres in the world securities market. The organization of public trading is controlled by Deutsche Börse AG.

³ It is worth noting that return, similarly to efficiency, is classified in absolute or relative values. Compare Bednarski, 2003, p. 59; Bednarski, 2007, p. 96.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

$$ROE_n = \frac{EAT_n}{\bar{E}}, \quad ROTAn = \frac{EAT_n}{\bar{A}},$$

where:

EAT_n – net profit in a given financial year,

\bar{E} – average accounting value of equity in a given financial year,

\bar{A} – average accounting value of total assets in a given financial year.

Additionally, measures of descriptive statistics i.e. classical and positioning measures of location and diversification were also used in the empirical research.

The second part of the research describes the application of the DEA (Data Envelopment Analysis)⁴ method which enables to calculate economic efficiency measures in a synthetic way. The efficiency ratio measured by this method can be described as a quotient of the weighted sum of inputs (see Dyckhoff & Allen, pp. 411-436):

$$e = (\sum_{r=1}^s \mu_r \times Y_r) / (\sum_{i=1}^m v_i \times X_i),$$

where:

e – measure of efficiency,

s – number of outputs,

m – number of inputs,

μ_r – weights describing significance of individual outputs,

v_i – weights describing significance of individual inputs.

It is stated in the literature that the DEA method is one of the most efficient ways of efficiency assessment in various economic entities (compare Cummins et al., 2010, p. 1526; Kao, 2014, p. 117; Lim et al., 2014, p. 361; Sahoo et al., 2014, pp. 921-922). It shows a number of attractive statistical features, including among others:

⁴ In the Polish literature the DEA method is known as the frontier analysis method or data envelopment analysis. It must be stressed that there are numerous publications in which the DEA method was applied to assess the efficiency of various entities e.g. power houses, hospitals, insurance companies, colleges, farms, joint-stock companies, industry sectors; or to evaluate efficiency of investment on the capital market. This method is most commonly used in the banking sector. Compare Halkos & Tzeremes, 2013, pp. 1658-1668; Fiordelisi et al., 2011, pp. 1315-1326; Chortareas et al., 2013, pp. 1223-1231; Rogowski, 1996, pp. 4-48; Ferús, 2006; Hülsmann & Peters, 2007.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

- it enables to analyse companies' activity which is characterized by a huge amount of inputs and outputs,
- it is not necessary to apply rank order scaling of inputs and outputs, thanks to which a subjective researcher's impact on the results is eliminated,
- it allows to consider various inputs and outputs included in diverse units, not only the monetary ones,
- it is not necessary to check functional dependence between inputs and outputs (no need for determining a production function),
- volume of inputs possible to minimize, or outputs possible to achieve with certain inputs are evaluated,
- it enables to discover extreme values that can be overlooked while using other methods because of the effect of data averaging (compare Rogowski, 1996, pp. 4-48).

Depending on the purpose of the analysis and assumed research assumptions, the DEA method offers an opportunity to calculate three forms of efficiency measures i.e. input-oriented efficiency, output-oriented efficiency, and efficiency without orientation. Moreover, there is the possibility to estimate efficiency measures in three categories: constant economies of scale, changeable economies of scale, and non-growing economies of scale (see Banker et al., 1984, pp. 92-1078; Fäare et al., 1985; Kleine, 2002, p. 210).

Table 1. Inputs and outputs in the DEA model

Variants	Inputs	Outputs
Variant I	<i>E, TA</i>	<i>ROTA, ROE</i>
Variant II	<i>E, TA, ΔE, ΔTA, D/E</i>	

Mark: *E* – equity; *TA* – total assets (total capital), *ΔE* – dynamics of equity, *ΔTA* – dynamics of total assets (total capital), *D/E* – debt-equity ratio, *ROTA* – return on total assets, *ROE* – return on equity.

Source: autor's own study.

For the need of the study a variant oriented toward inputs with steady economies of scale was applied. The choice of this model was dictated by the main research objective of the study that focused the analysis of factors determining economic efficiency on minimization of inputs. Classical

measures of return (equity and total assets) in entities were accepted as outputs whereas as inputs⁵ the author accepted:

- in the first variant – only accounting values of total assets and equity,
- in the second variant – accounting values of total assets and equity, ratios of their dynamics and ratios of capital structure, measured by a relation of debt to equity (debt-equity ratio) (see Table 1).

The essence and measures of company efficiency

The concept of „efficiency” is one of the most popular notions in economics and science of management as well as in general economic practice. However, it is often interpreted and understood ambiguously and used in diverse ways in management practice.

According to an encyclopedic definition, efficiency is perceived as a relation of outcomes to outlays (see *Wielka Encyklopedia PWN*, 2002, p. 53). The notion of efficiency often relates to a rule of rational management, taking a form of two variants: effective (maximization of outcome) and economical (minimization of outlay) (see Matwiejczuk, 2000, p. 27).

In the discussion on actions oriented toward obtaining new outcomes some attention must be paid to an attribute of their efficiency, combining effectiveness with efficiency, expediency and cost-effectiveness. Moreover, in the literature efficiency is often linked with such notions as: productivity, profitability, rationality or even purposefulness. In such a context it may be understood as not only an outlay-outcome relation, but also as an ability to adjust promptly to changes, to implement a strategy and to accomplish objectives, or as a tool for assessment of efficiency and effectiveness of actions (see Skrzypek, 1999, pp. 11-12).

The evolutionary development of defining efficiency is presented by M. Holstein-Beck who lists six categories composing a comprehension of content and range of the notion of efficiency. They include:

- productivity (in a techno-economic dimension by H.Emerson),
- competence (in an organizational-bureaucratic dimension by M. Weber),
- effectiveness (in a praxeological dimension by T. Kotarbiński),
- functionality (in a humanistic dimension by R. Beckhard),

⁵ What must be stressed here is the contractual character of the notions „inputs” and „outputs”. As far as connection of the term „output” with returns is justified in this study, the term „inputs”, which usually refers to costs, is used only to perform the role of customary terminology used in the terminology of DEA method.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

- communication (in a personality dimension by D.J. Lawless), and
- morality (in a behavioral dimension by K. Obuchowski).

However, in the light of the record of the organisation and management theory, it is assumed that efficiency is a primary category in relation to the above-mentioned notions (see Skrzypek, 2007, p. 214).

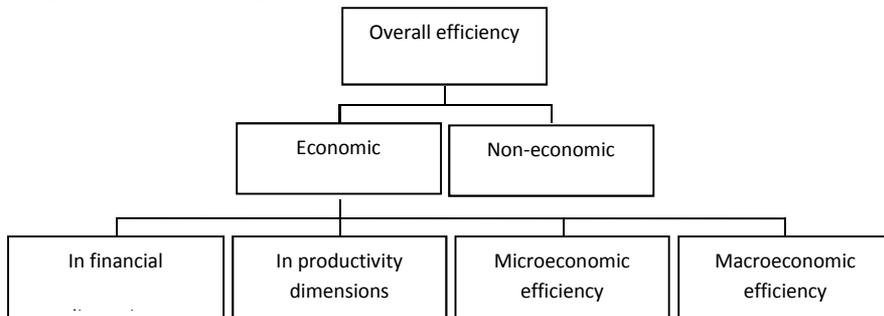

Taking the diversity and the inconsistency of defining the category of efficiency into consideration it must be pointed that there are two key approaches: purposeful and systemic, which significantly differ (compare Bielski, 2002, p. 109). The first one focuses on a degree of achieving set objectives and is identified with a notion of *effectiveness* (efficacy, purposefulness), the latter one focuses on a degree of using resources, which is described as *efficiency* (productivity, efficacy, cost effectiveness). As proof of the existence of differences in perceptions of these two approaches one can quote a statement saying that „effectiveness relates to doing things in a right way, whereas efficiency relates to doing the right things” (see Clark, 2005, p. 5). Being more precise, effectiveness is identified with cost effectiveness in the theory of competent activities. In economic reality, a desired condition is „a combination of effectiveness and efficiency with cost-effectiveness. Since it can happen that one can act efficiently but uneconomically and also one can do harm or act for benefit efficiently and economically” (see Niedzielski, 2011, p. 20).

Contemporary management of organisation also requires including a criteria of social righteousness (social effectiveness) (compare Nowosielski, 2008) as well as value for a client to the assessment of management competence. Simultaneously, what must be pointed out is a need for exclusion of allocative efficiency (allocation of resources according to customer preferences), or price efficiency (low prices while obtaining outlays and/or high prices while selling products) (compare Szydło, 2008; Szymańska, 2010).

The presented variety of approaches proves that scientific research on various aspects of efficiency must definitely be further conducted and discussed.

The subject of particular interest that is presented in the study is economic efficiency that derives from a rule of rational management and is defined as a difference between outcomes and outlays incurred in order to obtain these outcomes. It can be observed in financial and/or productivity dimensions and concern a single enterprise and/or the whole economy (see Diagram 1).

Diagram 1. Basic categories of efficiency

Source: autor's own study.

The foreign literature also presents the notion of overall efficiency that comprises technical efficiency and allocative efficiency (compare Aparicio et al., 2015, p. 882). It is also pointed out that there are a lot of studies on economic efficiency in technical and productive dimensions, whereas too little attention is paid to efficiency in a financial dimension, mainly when assessment of profits, costs etc. is concerned (compare Silva, 2014, pp. 108-112).

A very interesting approach to a modern perception of economic efficiency is the one presented by E. A. Helfert. The author points out that a basic economic objective of rational management is administration of selected resources at a strategic level in a way that in the long run an economic value will be created, ensuring not only covering but also a good return of incurred outlays without exceeding a level of risk accepted by owners (see Helfert, 2004, p. 427).

Economic efficiency is a category used, first of all, as a criterion of assessment of activity of the whole company as well as its specific areas. The importance of this category results from the fact that it prejudices the essence of enterprise as an economic entity, conditioning its functioning and determining its development (see Osbert-Pociecha, 2007, pp. 337-349). It concerns an ability to enhance a company's market position and improve its financial results. Moreover, acting in line with economic efficiency while taking decisions in enterprises is compatible with maximization of benefits for owners (see Wrzosek, 2005, p. 459).

The measurement of economic efficiency is an extremely complex and difficult problem of theory and practice of the assessment of enterprises' functioning and development. They result from diverse objectives, forms

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

and conditions of enterprise functioning, adverse expectations of stakeholders and changing concepts and practice of management.

In economic theory and practice an efficiency relation refers mainly to analysing outcomes with set outlays or using outlays in order to obtain assumed outcomes.

Efficiency understood as mutual relations between outlays and outcomes can be presented on the basis of three basic formulas:

- 1) efficiency as a difference between outcomes and outlays (profitability),
- 2) efficiency as a quotient of outcomes to incurred outlays (cost effectiveness), and
- 3) efficiency as a quotient of difference between outcomes and outlays to incurred outlays (rate of return).

When outlays and outcomes can be presented in measurable units, their collation enables to obtain the efficiency ratio that allows to make assessment in comparison with, e.g., a set base level, plan or efficiency of other units. Measures of efficiency are based on three approaches (see Szymańska, 2009, p. 159):

- a) ratio – constructing relations between various volumes (based on return, cost-effectiveness, productivity ratios),
- b) parametric – determining technical dependence between outlays and production, showing a maximum amount of product that can be obtained at a specific level of outlays – e.g. SFA (Stochastic Frontier Approach) method, TFA (Thick Frontier Approach) method, DFA (Distribution Free Approach) method, and
- c) nonparametric – using a procedure of linear programming – DEA method (Data Envelopment Analysis), FDH method (Free Disposal Hull) (see Charnes et al., 1978, pp. 429-444).

In spite of the fact that while assessing enterprises' efficiency a dynamic growth of interest in DEA and SFA methods (compare Lampe & Hilgers, 2015, pp. 1, 12) is observed, it must be stressed that ratio analysis still remains a relatively simple method of insight into economic operations and results of functioning of economic entities, as it concentrates on constructing relations between these volumes (compare Sierpińska & Jachna, 2014, pp. 144-145). It is very important, however, that these values are correctly estimated and interpreted, which is conducted on the basis of comparing obtained results with accepted reference bases. The literature presents a number of ratios used in assessment of economic efficiency of enterprises, which allow to conduct an analysis in a very broad range. These ratios in-

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

clude accounting, financial or market ratios that can be expressed in an absolute or relative dimension (see Table 2).

Undoubtedly, the efficiency measures that are most often analysed are return ratios, mainly because of their role and importance in assessment of financial situation formulated by creditors, owners and the State Treasury. Their application to management practice in enterprises faces certain constraints connected with, among others, accounting policy, focus on the past, disregarding risk and capital cost and structure. Measures of profitability and efficiency based on cash flow as a rule eliminate imperfections of accounting ratios concerning using various accounting rules, however, they have some disadvantages. Most of them were created in consulting companies which advertised them aggressively, creating temporal fads, moreover, they are very often used only to measure short-term achievements (see Dudycz, 2005, pp. 163-169). Market valuation, on the other hand, considered the most objective, is dependent on the situation in capital market, speculative operations, or established policy of stock market investors.

The weaknesses of efficiency assessment measures presented above seem, nonetheless, natural, especially in the light of inability to create an overall system of measurements of achievements and financial efficiency of enterprises, which could reflect their diversity and multiplicity as well as complexity of mechanisms shaping such efficiency.

Based on the empirical studies conducted on the basis of German concerns, it can be stated that only one third used market measures in the assessment of efficiency. Although nearly three quarters formulated their action objectives as value maximization, numerous enterprises used traditional profitability measures in financial controlling, taking accounting profit into account (compare Pellens et al., 1997, pp. 1933-1939). On the basis of the analysis of the biggest German public limited companies (from DAX index) it shows that in the majority of cases (more than 90%) relative measures of enterprise value were used and they were calculated on the grounds of the accounting profit (see Fischer & Wenzel, 2005, p. 25). Similar conclusions were drawn by other authors as well (see Hermann et al., 1999, pp. 399-406).

Empirical research results

The results of the conducted empirical research confirm the diversity of shaping of basic economic categories in Polish and German public limited companies in the period between 2004-2013. It is proved by calculated average values of equity and total assets as well as sales revenue (see Table 3).

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

Table 3. Average values of equity and total assets as well as sales revenue of companies included in WIG30 and DAX indexes between 2004-2013 (in million EURO*)

Specification	Index	2004	2005	2006	2007	2008	2009	2010	2011	2012	2013
Total assets	WIG30	4,4	4,7	5,5	6,7	6,6	6,9	7,6	7,5	8,2	8,5

	DAX	11,8	13,7	15,1	16,0	14,4	15,3	17,6	18,5	19,7	19,8
Sales revenue	WIG30	0,8	1,0	1,5	1,7	2,1	1,7	2,1	2,4	2,5	2,2
	DAX	31,1	32,8	36,3	35,5	36,6	33,3	37,7	40,9	44,4	43,3

* To calculate balance sheet data from companies listed in WIG30 an average NBP exchange rate on balance sheet date was used, whereas to calculate items of profit and loss account the used value was an arithmetic average of NBP exchange rates binding on the last day of specific months in a given year.

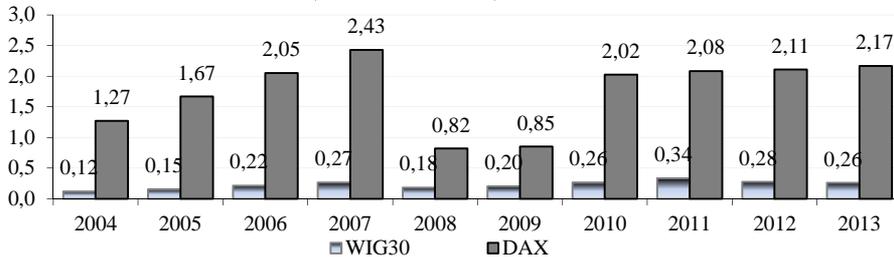

Source: autor's own study based on EMIS database, <http://www.boerse-frankfurt.de> and websites of analysed companies.

The figures presented in table 3 show unanimously that in the analysed decade companies included in WIG30 index achieved much lower values of equity and total assets as well as sales revenue than companies from DAX index. Differences in the value of total assets amounted to about 150 billion Euros on average, equity to about 15 billion Euros, whereas sales revenue to about 35 billion Euros. The biggest positive changes in values of these economic categories were observed between 2004-2007. A subsequent two-year period reflects some kind of market collapse that is described as crisis situation (compare Dach, 2011, pp. 33-36), whereas years between 2010-2013 show a relative growth of values of selected items of balance sheet and profit and loss account.

What should be underlined here is shaping of accounting measures of economic efficiency in absolute terms i.e. financial results of examined companies. The analysis of financial statements between 2004-2013 pointed at a certain regularity connected with a significant dominance of German companies over Polish enterprises (see Figure 1).

Figure 1. Average values of financial results of companies from WIG30 and DAX indexes between 2004-2013 (in billion EURO)

Source: autor's own study based on EMIS database, <http://www.boerse-frankfurt.de> and websites of analysed companies.

Moreover, three similar research subperiods were noted (between 2004-2007, 2008-2009 and 2010-2013), in which analysed measures showed diverse tendencies. What should be stressed here are more radical changes in values of financial results of companies from DAX index contrary to companies from WIG30 index, in particular in 2008 and 2010, in comparison with the previous year. What is also worth noting are differences in a reverse trend of economic efficiency that was observed in the last three years. When German companies showed an increase of economic efficiency, the Polish ones noted a decline in the average values of financial results.

While analyzing calculated measures of descriptive statistics it must be stressed that in German companies a more considerable diversification of financial results values was observed in the analysed decade than in companies from WIG30. It is also confirmed by values of standard deviations as well as minimum and maximum values in each analysed research period (see Table 4). In particular this situation was visible between 2011-2012, when differences between minimum and maximum achieved financial results amounted to a dozen billion Euros.

Based on the above-mentioned economic efficiency measurement conducted on accounting result categories in absolute terms it can be claimed that German companies achieved higher efficiency than the Polish enterprises. Presented in table 5 results of empirical research confirm, however, that economic efficiency of Polish companies measured in relative terms, in majority of cases is definitely higher than in German companies. It is also indicated by calculated average values of return on sales, equity and total assets ratios. Moreover, in companies from WIG30 index a bigger diversification of efficiency measures, especially one expressed by return on sales ratios, was observed.

It must be noted that in companies from WIG30 in each analysed year calculated average values of return on sales ratios were a dozen or several dozen percentage points higher than in companies from DAX index (see Figure 2). What is more, average values of return on total assets and equity ratios of the Polish companies, except four cases, exceeded measures of companies from the German stock market by a few percentage points. It confirms significant disproportions between average values of ROS, ROE and ROTA ratios in companies included in WIG30 and DAX indexes between 2004-2013.

Figure 2. Variations in average values of return on sales, return on total assets and return on equity in companies included in WIG30 and DAX indexes between 2004-2013 (in pp)

Source: autor's own study based on EMIS database, <http://www.boerse-frankfurt.de> and websites of analysed companies.

Special attention should be drawn to deviations between the analysed enterprises between 2008-2009, when the WIG30 companies, despite a market collapse, noted an increasingly higher return on sales and insignificant declines in return on total assets. In the DAX companies, on the contrary, observed declines in profitability ratios amounted to over 50 percentage points. Presented results confirm the hypotheses assumed at that time that effects of insolvency of American institutions immediately reached Europe, Germany in particular (see Romanie, 2008).

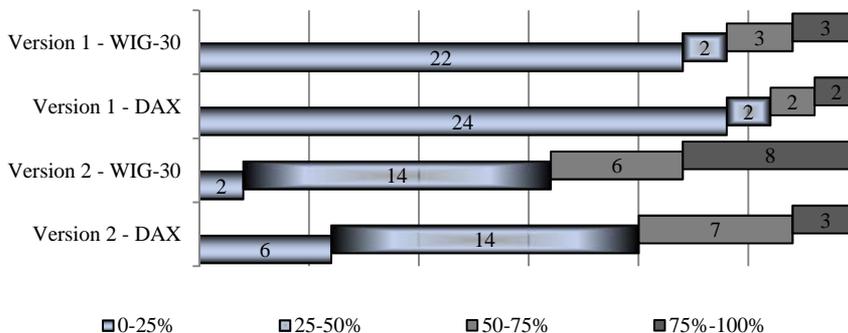

What is also worth stressing is the situation in the last analysed period when German companies significantly improved their economic efficiency

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

in every analysed area, and especially the one measured by means of return on equity ratio. As a result of a positive process the efficiency of the companies from DAX index in 2013 turned out to be higher than in the Polish stock market companies.

The results of the analysis of efficiency measures calculated by means of DEA Frontier software⁶ for 10 examined periods (between 2004-2013)⁷ showed that according to the first version of the model, the majority of WIG30 and DAX companies were characterized by efficiency lower than 25%⁸, whereas in the second version at the level between 25-50% (see Figure 3). Significant differences between Polish and German entities, in favour of the first group, were apparent in relation to DEA measures that confirm a high efficiency (75-100%).

Figure 3. Structure of analysed companies included in WIG30 and DAX indexes by their efficiency between 2004-2013

Source: autor's own study based on EMIS database, <http://www.boerse-frankfurt.de> and websites of analysed companies.

The detailed analysis of the examined entities from WIG30 index proved that according to the second variant the higher efficiency was observed in seven public limited companies: CCC, CYFROWY POLSAT, KGHM, LPP, PZU, SYNTHOS and TVN (see Table 6).

⁶ Free version available on the website within the study: Cook, W.D. & Zhu, J., 2008, *Data Envelopment Analysis: Modeling Operational Processes and Measuring Productivity*.

⁷ Specific efficiency measures were calculated on the basis of mean values of specific inputs and outputs for the period between 2004-2013.

⁸ Taking into consideration the constraints of the DEA method (positive values of inputs and outputs), negative values of specific inputs and outputs were replaced by a zero value. Compare Feruś (2006, p. 50).

In these cases efficiency measures were at the level of 100%. A similarly high efficiency from DEA's point of view (nearly 100%) was noted in EUROCASH. On the other hand, the lowest degree of efficient usage of capital outlays was noted in ALIOR.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

While conducting a thorough analysis of the entities from DAX index it must be stated that there were only two cases (K+S and SAP) in which one hundred per cent efficiency was achieved in the examined period. The lowest efficiency from DEA's point of view (below 10%) was observed in three enterprises: COMMERZBANK, INFINEON TECHNOLOGIES and THYSSENKRUPP.

Conclusions

On the basis of conducted empirical research it cannot be unequivocally stated that the Polish public limited companies, contrary to the German enterprises, were characterized by higher economic efficiency. It is a fact that the companies included in DAX index achieved definitely higher values of basic economic categories, financial results in particular, accounting measures of efficiency in absolute terms. On the other hand, generated profits did not translate into higher values of return ratios which make up accounting dimension of economic efficiency in relative terms. On these grounds the companies from WIG30 looked much better, both in relation to return on sales, total assets or equity. Similarly, however, less radical conclusions can be drawn on the basis of efficiency analysis by means of DEA measures. On the basis of this nonparametric approach, it must be stressed that German companies achieved, on average, lower efficiency ratios in relation to the companies from the Polish stock market.

The assumed research hypothesis can be considered empirically confirmed. However, the conclusions from the above-mentioned analysis cannot be generalised, but the results can be a significant contribution to further scientific research.

What can be undoubtedly stated is the fact that problems presented in the study which concerned a choice of forms, methods and tools of economic efficiency assessment in enterprises determine obtained results and thus, further conclusions and taking specific investment decisions. However, conducting a multi-factor and multi-dimensional analysis of company efficiency while using various approaches and accounting, financial and market measures, is indispensable to create assessment that will enable enterprises to develop and implement a system of efficient and effective management.

**Role of Institution, Government to Robust
International Entrepreneurial Activities
and Economic Growth: New Evidence**

JEL Classification: *C13; O47*

Keywords: *International Entrepreneurial activities; Economic growth; Development*

Abstract: This paper contributes to the development of the field of international entrepreneurial activities by providing answers to the following questions. Is higher human development generates opportunities to entrepreneurial activities that yields economic growth? What is the effect of the level on economic development on the relationship between entrepreneurial activities and countries growth? Do economic policies generate opportunity that yields higher international entrepreneurial activities?

The employed Generalized Method of Moments (GMM) estimation methodology is selected based on the long term dynamic of the entrepreneurial activities. Analysis is employed using panel data across two groups of countries based on their stage of development during the period 2004-2008. Empirical results provide a positive significant evidence for the role of human development to accelerate entrepreneurial activities and growth in innovative driven countries. The outcomes point towards the role of policies supporting entrepreneurial activities as a vital tool to accelerate development and growth via channels such as: better education levels, enhancing research and development, attractive taxes policies and stable monetary policy. This paper provides a comparative analysis of the empirical results and presents prospective explanations for the observed relationships between

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

different groups of countries to study the dynamics of change with relative short time series.

Introduction

Entrepreneurial activities have been studied and explained by prominent researchers making the notion even more (e.g., Baron & Ward, 2004; Markman & Baron, 2003; Mitchell et al., 2004). According to Schumpeter, 1934; Kirzner, 1973, entrepreneur role can be explained as an innovator, risk-taker and arbitrageur who participate to economic growth through creativity, new products and services, ability to compete at the international level. In social sciences, entrepreneurship is the creation of a new organization. However, the entrepreneur's role still remains uncertain as it is based on the human behaviour which is complicated and depends on the entrepreneur cognitive abilities, the surrounding environment that affects personality and the economic policies implemented in the country.

Existing literature has investigated the spill over factors to entrepreneur's activities and the constraints that hinder its dynamics and outcomes. But this might not tell the full story. Awareness has begun to shift to develop entrepreneur capital skills (see, e.g., Bloom et al. 2010, Bruhn, et al. 2010). This paper is assessing whether the human capital development can drive entrepreneurial activities to enter markets and what its dynamic role to growth? Finding an answer can be a good advice for developing countries and policy makers.

Empirical studies attempt to assess the relationship between entrepreneurial activities and economic growth which is ambiguous across countries. This vague relation attracts researchers to uncover these direct and indirect factors affecting entrepreneurial activities, via adding the role of human capital development. To accelerate entrepreneurs' role, researchers urge policy makers to adopt new tools that can increase human capital (Audretsch et al., 2001; Mueller, 2007; Shane, 2009; Henrekson and Johansson, 2010). This research investigates these missing links across countries and the spill over factors responsible for the growth. The extensive differences in economic performance across countries are considered a lucrative arena for research and policy makers for determining the main factors that develop these countries and help in enhancing their growth. I think that the differences between countries are rooted in the policies and regulations that encourage firms to operate successfully not only in the local but in the international market. The paper tries to answer whether

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

technological innovation, economic growth, and improvements in productivity is correlated with human development using different groups of countries. The study's contribution is based on finding the links between entrepreneur's activities, economic growth across countries based on classifying countries according to their human development index.

The study is of value to policy maker as it highlights the important role of human capital development. Moreover, the findings provide a set of policies for governments to undertake tenable actions to accelerate the effectiveness of the institutional setting. The structure of the paper is designed as follows: section 2 provides an overview of literature. Section 3 describes the model, data and variables used in this study; section 4 presents the empirical results and analyses and finally section 5 concludes the main points of the paper.

Literature review

Scholars from different fields are investigating the multiple impacts of entrepreneurship through different channels either operational, functional, production, per capita income, employment, standard of living, innovation and to help decision makers to robust their economies. This section tries to focus on the hypothesis of the changing role of the entrepreneurship across theories. It starts by defining the relation between human capital and entrepreneurship, entrepreneurship, followed by the role of entrepreneurial activities on economic growth.

Human capital development and international entrepreneurship

Differences in human capital is based on the type of investment that the individual can acquire through education, knowledge, skills and experience through formal and informal learning that increase individual impact on different levels (Becker, 1964, 93). Higher human capital increase individual wage, firms' productivity, and national economic growth, an evidence that shows the strong relationship between entrepreneurs and human capital (Schultz, 1961; Romer, 1989). Later, Teece (2011) suggests the existing of a strong relation between entrepreneurship and human capital, and argue the importance of a well-educated individual in the reformation of the economy. The role of human capital can be perceived across countries through measuring its impact on the national level. Measuring human capital is a vital starting point in terms of designing and implementing policies regarding human resources. Measurements are classified into conventional and non conventional.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

The conventional standard to measure human capital stock has been classified into three approaches: Output-, Cost-, and Income-based approach. First, the output approach is adopted by Romer (1990) as he proposes the ratio between skilled-adults and total adults to measure the stock of human capital at the national level. Later, Romer (1990) and Barro & Lee, (1993) measure the stock of human capital using “school enrolment rates” as a proxy. Moreover, the importance of education and training in the human capital field enhance the entrepreneurs’ qualities and help in creating new ventures depending on their education and experience (Griliches & Regev, 1995; Jones et al. 2010; Mosey and Wright, 2007). Later, Von Krogh and Wallin (2011) suggest that there is a relationship between time spent in schooling and lifetime earning as a result of opportunity costs. Despite the drawback of this approach, the students’ effectiveness cannot be achieved except after enrolment in the production activities.

Second, Cost- based approach is based on the total amount of money invested in human capital. Jorgenson & Fraumeni (1989) employed a discounted income analysis, but this approach face difficulties in splitting what is for investment and what is for consumption. But the third approach which is the Income-Based Approach, provide a link between the stocks of human capital utilizing an individual’s income (Mulligan & Sala-i-Martin, 1995). They show that individual with higher stocks of human capital and various skills are able better to make use of their resources in entrepreneurship activities than in a salaried job (Williams, 2004). However, this approach face a drawback as it ignores other factors that can affect the individual income, such as family health, fertility and child morality (Lewin et al., 1983; Woodhall, 2001).

To overcome the drawback of the conventional measures, in 1990, a new Human Development Index (HDI) by the United Nations Development Programme (UNDP) has been developed. The index is based on health, knowledge, and standard living with many sub-variables such as life expectancy at birth, adult literacy rate, gross enrolment ratio, and GDP per capita. In September 2006, the OECD launched a new Entrepreneurship Indicators Programme (EIP) to build internationally comparable statistics on entrepreneurship and its determinants. This indicator is closely attached to education-related factors such as high-level qualification, graduation and enrolment rates, invested time in education, and investment in education (Hansson, 2008). These non conventional measures encourage researcher and policy makers to recognize the driving force to growth.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

Furthermore, Porter (1990) and Porter et al. (2003) relate the country stage of economic development with its competitive advantage, as the country transfer between the following stages of development starting with: (1) factor-driven stage; a stage that depend on the inherited natural resources factors and the created factors by the human; (2) investment / efficiency-driven stage and (3) innovation-driven stage; (4) wealth driven stage. First, countries in factor-driven stage compete through producing products depending on its low cost. Almost countries with abundant natural resources practice this stage, as they neither develop knowledge for innovation nor use knowledge for trading. In the second stage, countries must increase their production efficiency and educate the labor force to be able to adapt in the preceding technological development phase. Countries in this second stage (investment/ efficiency) must use their efficient productive practices and be able to compete in the international markets relying on their economies of scale (Acs Z. J. et al. 2007; Acs Z. J. et al.2008). Emerging markets are opt to lower barriers to entry, deregulation and trade liberalisation, and change their institutions and enforce encouraging business laws, Chang, (2012), Yamakawa, Peng & Deeds, (2008). While, the innovation-driven stage, countries in this stage are very sensitive to the international changes such as exchange rate, price level, countries opt to compete depending on their high level in technology and economies depend on the private sector. Finally, the wealth driven stage, is characterised by the ability of the countries to keep the previous achievements, D. Greasley and L. Oxley (1996).

In table one countries are classified according to their stage of development in stage three many countries are characterised with offshore financial centers, sound economic policies and qualified labour deepen the entrepreneurial activities and increase entry density through creating more competitive advantages. In factor driven stage countries which are endowments with resources but they lack qualified labour, sound economic policies and attractive investment environment these factors enhance countries potentiality to compete internationally. In the light of globalization and the fast technological development the role of international entrepreneurship is changing. The international entrepreneurship concept is better defined as "...a combination of innovative, proactive, and risk-seeking behaviour that cross national borders and is intended to create value in organizations" (McDougall & Oviatt, 2000; Oviatt & McDougal, 2005). Emerging countries discourse to internationalisation and venturing need to consider entrepreneurship as a key driver of economic development, (Song, Wang and

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

Parry, 2010). Entrepreneurs may have an extraordinary role in sustaining national growth and development. However, national differences still exist due to the stage of development inside the country. Researchers investigate the key reasons of these differences and they refer it to national political/legal, economic, and social contexts (Baughn & Neupert, 2003; Lee & Peterson, 2000).

Economic growth and International Entrepreneurship

International entrepreneurship has been defined as the ‘discovery, enactment, evaluation, and exploitation of opportunities—across national borders—to create future goods and services’. Historical views links entrepreneurship and economic growth with various fields of economics and management study, including economic history, industrial economics and management theory. The interrelation between various sciences field attracts researchers to uncover these relations. Schumpeter (1934) in his seminal book *The Theory of Economic Development* argued that not all businessmen are entrepreneurs; they must be innovators and a catalyst to the production process by adopting new technology. Furthermore, researchers have begun to study the endogenous factor affecting growth through technical change resulting from decisions of profit-maximizing agents. The latest class of models developed in this tradition has risen from the works of Romer (1986, 1990), and Lucas (1978). Later, endogenous growth models highlight the importance of knowledge as determinant to economic growth, while the new class of endogenous growth model pioneered by Romer (1990) identified some attributes of entrepreneurship by modelling the process of invention and deriving the motives for invention from the microeconomic level.

Researchers on pre-20th century economic history show that entrepreneurs adopted new production techniques, reallocated resources to new opportunities, diversified output and penetrated new markets via competition. In the mid-20th century, entrepreneurship role declined in the light of the production large-scale and efficiency. In the last two decades, the knowledge and information revolution has renewed theoretical thinking linking entrepreneurship to growth with new theories emerging from the field of industrial evolution or evolutionary economics (Jovanovic, 1982). The evolutionary economics view entrepreneurs as agents of change, bring new ideas to markets and accelerate growth through a process of competitive firm selection. Wennekers and Thurik (1999) showed that the general

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

innovative role of entrepreneurs includes not only newness (implementing inventions), but also new entry (start-ups and entry into new markets).

Empirical studies of entrepreneurship and its relationship to economic growth are all relatively recent. Carree and Thurik (1999), followed by Audretsch et al (2002), concluded that those OECD countries present an evidence for higher increases in entrepreneurship, exhibited through business ownership rates, and they are the ones that have enjoyed lower unemployment and greater rates of economic growth. In most of these studies, the commonly used proxy for measuring entrepreneurship was business start-up rate. Acs and Armington (2002) have investigated the relative contribution of new start-ups to job creation. Their findings suggest that new firms may have a far greater role in new job creation than previously thought. Creating jobs can be directly linked to economic growth and supporting entrepreneurial activities is a powerful force driving innovation, productivity, job creation and economic growth. The effect of entrepreneurial activity on economic growth depends upon the level of per capita income and economic growth. Depending on macro data available, one could use proxies capturing a single feature and its level as a measurement of entrepreneurship. However, “recent empirical studies suggest that entrepreneurship – measured as start-up rates, the relative share of SMEs, self-employment rates, etc. – is instrumental in converting knowledge into products and thereby propelling growth” (Braunerhjelm, 2010). The relation between entrepreneurial activities and economic growth has received increased attention of researchers and policy makers, particularly in developing countries as they endure high unemployment rate. Entrepreneurship has been a solution to high unemployment and stagnant economic growth (Carree & Thurik, 2001; Van Stel et al, 2005; Thurik et al, 2007). Later, ACS and Szerb (2007) measure the relation between the entrepreneurial activity and economic growth in poorer countries and show the negative impact between them. It is important to assess the relationship between economic growth and entrepreneurship across countries, in particular since the ambiguities within this relationship can insight policy makers.

The importance of economic growth attributes to set a sound governmental policies, transparent institutional structure, and wealth to generate entrepreneurial activities which are the sources of development and economic growth. Thus, adopting policies to promote knowledge and improve labor skills to encourage entrepreneur activities, particularly through fiscal policies, is a long term plan. Entrepreneurship determinants on the macro level are explained by demand side determinants (named push factors),

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

representing technological developments, the industrial structure of the economy, government regulation, and the stage of development, (Wennekers and Thurik 1999; Wennekers et al., 2002). While, the supply side determinants (named pull factors), represents demographic characteristics of the population, income levels, educational attainment, unemployment level, cultural norms, access to finance, and the degree of taxation. Recent studies by Blanch flower et al, (2000) found that the level of education has a negative effect on the probability of an individual selecting self – employment. They reasoned this as the highly educated people may not be willing to be risk taker, and this result is supported by van der Sluis et al, (2005). Consequently, innovation and entrepreneurial activity are the drivers of long-run economic growth.

Methodology of the research

The purpose of this paper is to shed some light on the possibility of obtaining a better understanding of causal linkages between the entrepreneurial activities and economic growth by analysing the main tools that accelerate growth in a panel context. The countries under study are classified based on the stage of economic development. The first stage is the factor driven stage, economies are considered to be at the lowest stage of economic development, in this group countries utilize the abundant primary resources to increase its international competitiveness and to adjust to several institutional setting to become transparent, accountable, and creditable country. The more the economy develop its resources targeting more efficiency in utilizing resources the more it become able to gain competitive advantage, than they turn into efficiency driven economies. As for stage three; it is innovation driven stage creating new knowledge for international competitiveness. The list of countries is grouped according to their development stage, see table 1. As is evident from Table A, there is a considerable variation in entry density across countries and time periods. In the country with the lowest entry density (Burkina Faso) there were only 0.06 new registrations per 1,000 people within 4 years, whereas in the country with the highest entry density (Cyprus), provide 26.71 new registrations per 1,000 people within 4 years.

The econometric analysis of this kind should account for a number of specific steps. First, a non-stationarity of the time series variables must exist and appropriate panel unit root tests must be performed. Secondly, if the time series are non-stationary, a panel cointegration approach is needed

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

to test if a long-run equilibrium relationship exists between non-stationary variables. Then there is a high probability that the included variables are endogenous so that the models should consider the existence of Granger causality¹. The following are the steps followed in this paper:

Unit Root tests: Panel data techniques could also be preferable because of their weak restrictions; indeed, they capture country-specific effects and heterogeneity in the direction and magnitude of the parameters across the panel². In this study, the considered tests employed five different unit root tests including LLC's test, Breitung's t-statistic, IPS-W-statistic, ADF-Fisher Chi-square, and PP-Fisher Chi-square tests, whereas a robustness check has been carried out on single cross section units to investigate the existence of structural breaks. The paper didn't perform a panel unit root tests with structural breaks because it is almost impossible to have homogeneous breaks in time series in a significantly heterogeneous panel like the one we have considered especially for variables such as firm density income and economic growth.

Panel co-integration analysis: To determine whether the regressions are spurious, the results of the panel co-integration tests must be examined. Given the results, it is appropriate to test the co-integrating relationship between the three variables. In this study it employed Pedroni's co-integration tests that suggest two types of residual-based tests for the test of the null of no cointegration in heterogeneous panels³. These tests reject the null of no cointegration when they have large negative values except for the panel-v test which rejects the null of cointegration when it has a large positive value. However, according to Pedroni (2004), r and pp tests tend to under-reject the null in the case of small samples.

¹ From the advantage of using panel cointegration is that it allows for heterogeneity between countries. Moreover, the number of observations available while testing the stationarity of the residual series in a level regression is greatly increased in a panel framework and this can increase the power of the cointegration tests (Rapach and Wohar, 2004).

² One of the primary reasons for the utilization of a panel of cross section countries is important to tests them integration between variables involved in the research conducted.

³ For the first type, four tests are based on pooling the residuals of the regression along the within-dimension of the panel (panel tests); for the second type, three tests are based on pooling the residuals of the regression along the between-dimension of the panel (group tests). In both cases, the hypothesized cointegrating relationship is estimated separately for each panel member and the resulting residuals are then pooled in order to conduct the panel tests.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

GMM technique: Generally, the GMM technique can be adapted to estimate the panel variables, using lags of the endogenous variables as instruments in order to arrive at unbiased and consistent estimates of the coefficients. In a panel of N countries covering T years, this approach estimates the model parameters directly from the moment conditions that are imposed by the model. GMM doesn't require distributional assumption, like normality, it can allow for heteroskedasticity of unknown form, and it can estimate parameters even if the model cannot be solved analytically from the first order condition.

In this study it utilize single equation approaches assuming there is homogeneity between cross section units for the long-run relationship whereas short-run dynamics are allowed to be cross-section specific. While this restriction may seem too severe for some variables, on the other hand, allowing all parameters to be panel-specific would considerably reduce the appeal of a panel data approach. The data collected information on 58 countries, divided into three groups: group one 21 countries, second group consist of 18 countries, and third group consist 19 countries, as listed in Table 1 in the Appendix. But group three observations are not sufficient to be estimated, thus factor drive countries are not applicable for estimation. The considered specification of the dynamic model for firm density is lagged endogenous model to reflect the entrepreneur activities with joint dynamics variables as follows:

$$\ln(ED_{i,t}) = \alpha_i + \lambda \ln(ED_{i,t-1}) + \beta_1 \ln(GDPG_{i,t}) + \beta_2 \ln(RD_{i,t}) + \beta_3 \ln(GDPD_{i,t}) + \beta_4 \ln(TAX_{i,t}) + \beta_5 \ln(Trade_{i,t}) + \beta_6 \ln(SES_{i,t}) + \varepsilon_t \quad (1)$$

The following table 2 summarizes the variables used in the estimation of the model, and the instrumental variable included in the estimation, with their respective to descriptive statistics.

Conclusions

Unit root tests have been computed under two different specifications, represented by the inclusion of individual effects or individual effects and trends as reported in Table 3. The unit root hypothesis cannot be rejected when the variables are taken in levels and any causal inference from the series in levels would therefore be invalid. However, when using the first differences, the null of unit roots is strongly rejected at the 1% significance level for all series. Therefore, it is concluded that all the series are non-stationary and integrated of order one. This finding is confirmed by all the tests employed in all the three alternative country samples that are under examination. The variables properties need to avoid the possibility of spurious regressions. In order to assess the stationary of the variables employed, this paper employs five different unit root tests including LLC's test, IPS-W-statistic, ADF-Fisher Chi-square, and PP-Fisher Chi-square tests. The results of these tests are reported in table 3 indicating the statistics significantly of the variables, as they are stationary at the level values especially for the LLC's test at the 10%.

The unit root hypothesis cannot be rejected when the variables are taken in levels and any causal inference from the series in levels would therefore be invalid. However, when using the first differences, the null of unit roots

is strongly rejected at the 1% significance level for all series. Therefore, it is concluded that all the series are non-stationary and integrated of order one. Therefore, a long-run relationship exists between economic growth and entrepreneurial activities.

An analysis of cointegration on multivariate models including economic growth for the three group of countries, which strongly supports the existence of a long-run relationship demonstrating that the inclusion of the relation between economic growth and entrepreneurial activities represented in the firm density and to reinforce the statistical robustness of the linkages between the variables are examined here. Tests conducted on the period 2004 -2008 for multivariate models were with full heterogeneity results are presented in table 4. The panel cointegration tests revealed the existence of a long-run co integrating relationship between the economic and the energy dimensions in all the enrolment to secondary schools, research and development, ICT goods exports, trade and pricing policy in the innovative stage countries.

Empirical Results

Empirical results provide the answer for the first question showing the direct and significant relation of entrepreneurs on economic growth and trade. Using panel fixed effects to test for main variables affecting the firm density, results for the countries under study presented in table 5 shows the positive significant relationships between ED and economic growth with the level of significance at 1%. The sign of the coefficients estimated support previous literature and previous empirical studies. In this study economic growth effect is more in the innovative stage than efficiency stage countries, as estimates of the coefficient of economic growth is (0.1) while efficiency stage countries estimates is (0.02) reflecting the relative contribution of ED on economic growth. In addition, the trade and entry density shows a positive and significant relationship, as estimates of the coefficient of trade is (0.13) in innovative stage countries while it is (0.05) in efficiency stage explaining the effect of ED on trade. Future more, taxes have a negative impact on entry density in innovate drive countries but it is insignificant, while efficiency driven countries it provide negative and significant relation at 1%. This reflects the sensitivity of each group to the tax policy as in efficiency driven countries tries to increase investment and provide more incentives.

Moreover, to assess the relation between school enrolment and entry density, as literature shows that countries that are characterized with higher human development, higher school enrolment, higher income level, and better health standards have direct effect on economic growth. Empirical results in the two groups provide the positive and significant effect of school enrolment and entry density in innovate driven countries as estimates of the coefficient of school is (0.4) while in the efficiency driven stage countries the relation is negative and its estimates of coefficient is weak. Such results reflects one of the reasons of reaching innovative driven stages and the important contribution of a qualified education increase the human capital investment and consequently increase the labor productivity.

In addition to the importance of entrepreneurial activities the economic policies participates to create an attractive business environment to increase entry density. Last model results presented in table 5 model 5 and 6 shows the positive significant effect of inflation rate on entry density, as estimates of coefficient is (3.18) in innovative stage countries and (0.082) in efficiency driven countries.

Implication and limitation

This paper has analyzed the factors explaining the role of entrepreneurial activities across countries in a dynamic panel data frame work in a macroeconomic using macroeconomic perspective. Three analyses are carried across innovative and efficiency driven countries, the study used a dataset of for the 39 countries, thus allowing a number of considerations on different results emerging from alternative subsamples.

Results shows how to develop an economy and shift it to the stage of innovation as requires a system based on skilled labour, a system that acquire knowledge, develop it, maximize its utilization and able to create competitive advantage in any sector. The ability of countries to invest and build their economic systems based on knowledge this gives them the advantage to create competitiveness within the global environment and accelerate their outcomes. Investing in education, R&D which led to the stage of efficiency in this stage country will be able to create competitive advantage and develop their economies to reach take off stage. Innovative stage countries, such as Finland, were able to shift from intensive resource industries to an economy specialized in information technology during the period from 1970 to 1990. On the other side, Factor driven countries are suffering

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

from the loss of skilled of labour, a problem that hinder development in these countries and create a loss in managerial skills and skilled labour.

Based on the finding and research implications, the following policy measures are recommended. Research and development, qualified education system, sound economic policies are important determinants in attracting entrepreneurs and increase economic growth. In this point of view, decision makers need to improve and increase the budget allocation to research and development that is channelled to increase technological advancement. Financial support programs & grants are needed to support firms to develop new products. Moreover, monetary policy play a vital role in attracting entrepreneurship, as higher rate of inflation increases the cost to start a business, increases the country risk. Decision maker are required to control inflation as higher rate has a negative impact on economic growth and entrepreneurial activities.

Worth mentioning that this paper didn't focuses on the other side of the picture by including factor driven countries but this limitation is refereed unavailability to source of macroeconomic variables. In the future, a similar study can be conducted with increased number of observations and extending the time frame and adding more control variables.

**Budgetary Allocation and Poverty situation
in Nigeria: the Implication for Economic
Insecurity**

JEL Classification: *E62*

Keyword: *Budget; Poverty; Insecurity; unemployment*

Abstract: In any federal entity which is polarised along religion and tribal line, disagreement on how to share the national cake would pose enormous threat to a peaceful coexistence. Unemployment and poverty are endemic among Nigerian youth in spite of numerous approaches to curtail the menace. This study examines the relationship between budgetary allocation the level of poverty Nigeria. The study uses time series data covering 1999-2012 periods. The paper applied bound approach to cointegration. The study also used Vector Autoregressive model and Vector Error Correction Model to examine the dynamic causality among the variables. The study reveals that causality exists between budgetary allocation and the poverty rate in Nigeria. The paper therefore concludes that budgetary allocation can be used as a tool for poverty reduction. The study recommended that the need for realistic budgetary allocation formula becomes imminent. In such arrangement more weight should be accorded to the population size, internal revenue efforts and social development factors while inequality to the states ought to be reduced. This would ensure economic security which is fairly inadequate in the present arrangement.

Introduction

Achieving equitable revenue allocation in Nigeria constitutes the perennial problems which has not only defied all past attempts at permanent solution, but also has a tendency for evoking high emotions on the part of all concerned (Ojo, 2010). It is an issue which has been politicised by successive administrations in Nigeria both military and civilian regimes. Indeed, in virtually all federations in which the constitution shares power between the central and regional or state governments and, for each level to be within a sphere co-ordinate and independent enough resources need be allocated to each tier to justify their existence (Wheare, 1963). The ways government budgets are allocated have an important impact on economic development thereby bring government closer to the people (Gupta, Clements, Guen-siu and Leruth, 2001). Before the discovery of crude oil and the time when agriculture was the mainstay of Nigerian economy, contending issues relating to derivation principle is silent in the revenue allocation. However, with the discovery of oil and the subsequent oil boom of 1970s made Nigeria solely dependent on oil sector as a source of foreign exchange and neglected the traditional sector with hitherto accommodates over 70 per cent of the productive youth, in addition of been the source funding to the public authority.

The repercussion of skewed revenue allocation among the federating states of Nigeria constitutes the perennial problems which have not only defied all past attempts at permanent solution, but also has a tendency for evoking high emotions on the part of all concerned (Ojo, 2010). The distribution of the problem is not equal. The magnitude of economic crisis within geo-political zone reflects the relative low budgetary allocation received from federal government. This amount to say geo-political zones with the relative high budgetary allocation enjoys more welfare and economic stability. This study tends to investigate the relationship between budgetary allocation and poverty situation in Nigeria. The paper is divided into five sections including this introduction. Section two contains data and methods employed in the study, section three reviews the literature analysed the data on budgetary allocation dynamics. Fourth section presents a glance on Nigeria's poverty situation; and the last section concludes the study.

Methodology

This study employed descriptive statistics in analysing the data. Descriptive statistics is an event or outcome of events that are described without drawing conclusion(s). It is primarily concerned with the collection, organisation, summarising, analysis and presentation of an array of qualitative and quantitative data (Monga, 2009). The data for the relevant variable (budget and poverty) covers 1999 – 2010 period. The choice of the period is not unconnected with the return of democratic dispensation as well as commitment of the elected leaders to implement series of market-based policies aimed at winding the engine of growth.

Budgetary Allocation Dynamics

In a federal system of government, revenue allocation involves two schemes. The first is the vertical sharing between the federal or inclusive government and the other tiers of governments. The subject of these sharing schemes is the federally collected revenues. This is because the revenues generated within the jurisdictional areas of the units – states and local governments – are not subject to the national sharing formula (Ogbole and Robert, 2012).

Ricardian Equivalence Hypothesis exhibits that dynamics in the budget allocation has a first order effect on savings in any society. Since, a reducing tax does not affect households' lifetime wealth because future taxes will go up to offset current tax decrease (Ibrahim and Ibrahim, 2014). Therefore, current private saving rises when taxes fall, households save the income received from the tax cut in order to pay for the future tax increase. Consequently, a budget deficit would not cause a twin deficit of budget deficit and trade deficit; instead it would perpetuate dualism in the economy (Asrafuzzaman, Roy and Gupta, 2013). Meanwhile, a participatory budgetary process may not yield immediate victories for citizens but it may serve to enhance communication and trust between government officials and citizens (Cole 1975; Adams, 2004), leading to reinvigorated levels of popular participation. Such efforts may also serve the long-term goal of enhancing governmental accountability and responsiveness because public officials may begin to attribute more importance to citizen input (LaFrance and Balogun, 2012).

The debate on Nigeria's fiscal federalism and relations hinges on the fundamental question of who gets what of the national cake, when and

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

how. This is fundamental, given that Nigeria as a monolithic economy gets over 80% of its revenue from crude oil, by virtue of the constitutional provision, this revenue must be disbursed to the three tiers of government. It also explains why the formula for revenue allocation has continued to be at the heart of public debate and why public officeholders are hardly held accountable for the misuse of revenues derived from the national oil wealth. It is obvious that the nature and conditions of the financial relations in any federal system of government are crucial to the survival of such a system. A major source of inter-governmental disputes under a federal system centres on the problems of securing adequate financial resources on the part of the lower levels of government to discharge essential political and constitutional responsibilities (Olaloku, 1979). The existence of a federal system with its accompanying political units necessitates a revenue sharing arrangement to enable its units to carry its constitutional assigned responsibilities (Chijioke, Innocent and Jeffery, 2012).

Meanwhile, it is imperative to note that Nigeria's revenue sharing debates have revolved basically around three issues. Firstly, the relative proportions of federally collected revenues in the federation account that should be assigned to the centre, the states, the localities and the so-called 'Special Funds' (vertical revenue sharing); Secondly, the appropriate formulae for the distribution of centrally devolved revenues among the states and the localities (horizontal revenue sharing); Thirdly, the percentage of federally collected mineral revenue that should be returned to the oil-bearing states and communities on the account of the principle of derivation and compensation for the ecological risks of oil production (Ogbole and Robert, 2012).

Horizontal revenue allocation deals with the distribution of funds within the same tier of government among states the federating state on the one hand, or within the local government in a state on the other hand. Several principles adopted in the country with the ultimate goal of finding more acceptable formula, however most of these principles have been contentious, since states usually prefer principles that favour their specific peculiarities, which often constitute the primary source of conflict and agitations (Okojie, 2008). Table below summarizes the horizontal revenue allocation formula from 1980 – date.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

Table 1. Horizontal revenue allocation formula

Principle	Revenue Allocation Act (%)	Babangida Administration (%)		Abacha Administration (%)	Obasanjo Administration (%)	
	1981	Jan 1990	Jan 1992	1994-1998	1999-2004	2005-Present
Equality of state	40.0	40.0	4.0	40.0	40.0	45.23
Population	40.0	30.0	30.0	30.0	30.0	27.05
Social Dev. Factors	15.0	20.0	10.0	10.0	10.0	8.71
Internal revenue efforts	5.0	10.0	10.0	10.0	20.0	8.31
Land and terrain	-	-		10	-	10.7

Source: Imam, 1999; Iyoha, 2000; RMAFC, 2005; Okojie, 2009; Ibrahim and Ibrahim, 2014

It is evident from the Table 1 above that variation in the equality of the state is relatively steady with the notable exception in the year 2005 when it rose from 40% to 45.23%. Meanwhile, the allocated revenue based on population of state decline from 40% in 1981 to 30% through 1980 down to 2004 and it further drops to 27.05% in 2005.

Nigerian government laid down proactive process aimed at making the budget to act as an engine of growth. Accordingly, the constitution of the Federal Republic of Nigeria Section 162 stipulates that all federally-collected revenue should be paid into the Federation Account monthly and shared among the three tiers of government. These revenue components are made-up of oil and non-oil revenues. The oil revenues include proceeds from sales of crude oil and gas, Royalties, Petroleum Profit Tax, Rentals, Gas Flared and Miscellaneous oil revenue. The non-oil revenues include Company Income Tax (CIT), Import Duty, Excise Duty, Fees, tariffs, Customs Penalty Charges. The responsibility of sharing is discharged by Federation Account Allocation Committee (FAAC) at its monthly meetings statutorily chaired by the Honourable Minister of State for Finance, with Honourable Commissioners for Finance and Accountant Generals of the 36 States, and the Director of Treasury representing the Federal Capital Territory (FCT) as members (NPC, 2011).

It should be noted that in order to ensure equitable parameters' for the sharing of the revenues to the three tiers of Government, an independent body was created by the constitution and named Revenue Mobilization

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

Allocation and Fiscal Commission (RMAFC) to consider every factor affecting the share of each tier of Government and come up with an acceptable Revenue sharing formula for the Federation.

In the light of above, the current sharing formula is as follows:

Table 2. Sharing formula

Federal Government of Nigeria (FGN)	48.50%
Ecological	1.00%
FCT	1.00%
Stabilization Account	0.50%
Development of National Resources	1.68%
Sub-total	52.68%
State Governments	26.72%
Local Governments	20.60%
Total	100.0%

Source: own work.

Oil producing states (9 States) receive 13% derivation which is deducted up front.

Value Added Tax (VAT) is shared among the three Tiers of Government separately using a different formula as follows:

Table 3. VAT sharing formula

FGN	15%
State Governments	50%
LGAs	35%
Total	100%

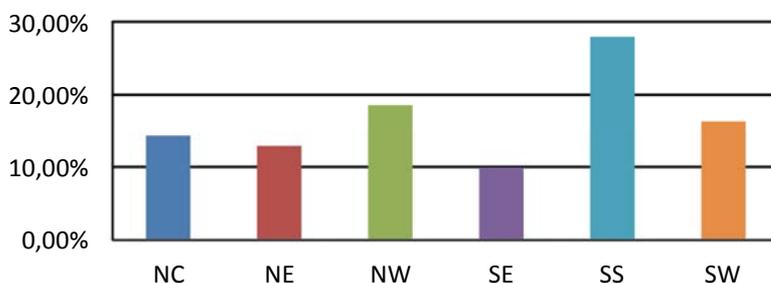

Source: own work.

The Excess Crude Account (ECA) which has now metamorphosed to Sovereign Wealth Fund (SWF) was created by FAAC to warehouse excess oil revenues over the predetermined budgeted benchmark price of crude oil. The policy is in line with the Fiscal Responsibility Act of 2007 and Government responsibility of managing the economy as one entity. It is very clear that the present sharing formula is skewed in the allocation of fund to states. Apart from the statutory allocation earmarked for each state of the federation equally, certain amount (13%) is set aside for oil producing in the name of derivation. This bad omen made some state especially in the

northern part of the country to be operating from hand to mouth (gigantic recurrent expenditure and less for capital project).

In compliance with provision of the above revenue allocation formula, the allocation among the seven geopolitical zones was not far from unequal nor does contain any element of equity. For instance, in 2010 south-south received approximately 28% of budgetary allocation compared to tiny amount allocated to north-west which is approximately 13%. Moreover, north-central received 14%, north-east with 13%, 10% and 16% were allocated to south-east and south-west respectively.

Figure 1. Budgetary Allocation by Geo-Political Zone (2010)

Source: own calculations based on OAGF; 2011.

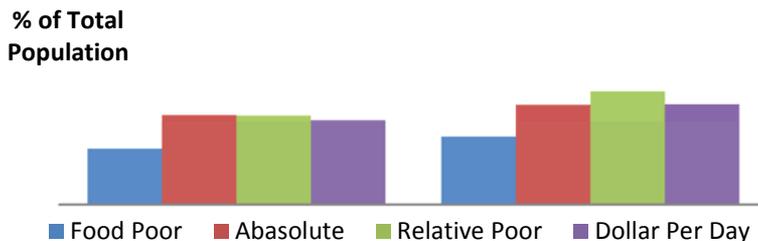

Poverty Situation

The primary objective of any economic policy of Government is to achieve improvement in the living standard of the people, particularly, in terms of alleviation of poverty. Available data from the Harmonized Nigeria Living Standard Survey (HNLSS) 2009/2010, which remains the follow-up to the Nigeria Living Standard Survey (NLSS) 2003/2004, conducted by the NBS reveals that efforts to alleviate poverty was not satisfactory. For instance, relative poverty and absolute poverty rates increased to 69.0% and 60.9% in 2010 respectively from 54.4% and 54.7% in 2004. This implies that the population in relative poverty grew by a compound annual growth rate of 8.56% above the average growth rate of 7.2% per annum since 2004, indicating further that the economy must increase above 8.56% per annum for economic growth to trickle down to alleviate poverty to an acceptable level. However, there was a slight decline in the percentage of population below one dollar per day by Purchasing Power Parity (PPP) from 62.8% in 2004 to 61.2% in 2010 (NBS, 2012). The highlight is in

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

Figures 2.1 and 2.2. The need for the costs of governance to reduce drastically, particularly, by cutting down recurrent expenditure, specifically, the number of aids, ministries, departments, agencies, wastages, etc is glaring. It is also supportive to place more emphasis on capital projects.

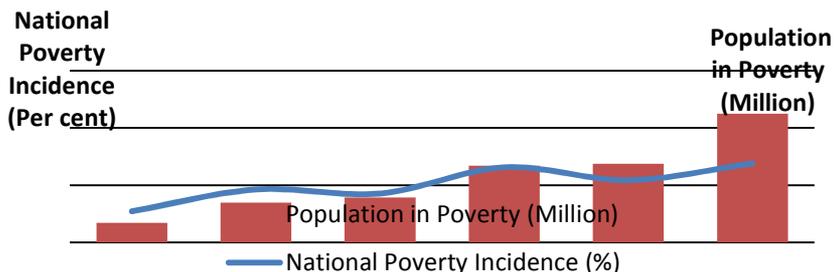

Figures 2. National Poverty Incidence (2004 versus 2010)

Source: NBS, 2012.

The rate of poverty was more prevalent in the rural areas than in the urban areas. Relative poverty and absolute poverty rates were 73.2% and 66.1% respectively in the rural communities in 2010 as against 61.8% and 52.0% in the urban areas. Similarly, the population living below one dollar per day was 66.3 % in the rural areas, compared with 52.4% in the urban areas. The foregoing results pinpoint the need for rural development and economic emancipation of the rural populace. The proposed constitutional review at the National Assembly aimed at ensuring financial autonomy for the Local Government Areas (LGA) in the country through the termination of the Joint State and Local Government Account is a step in the right direction. This is good for rapid growth and development of the grassroots where majority of the poor resides.

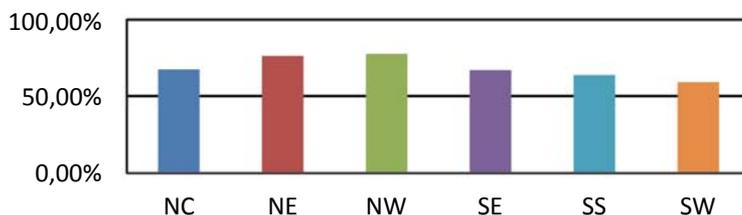

Figures 3. National Poverty and population in poverty

Source: NBS, 2012.

The replica of the imbalance revenue sharing formula is the existence of wide disparities among the federating units. For instance, poverty spread among the geopolitical zones concurred with the unequal budget allocated to the respective zones in the country. The absolute poverty was more severe in north-west accounting for about 78% of the population in that region (see chart below). North-east appeared to be the region with the second highest level of poverty containing about 76% of abject poor, 68% was recorded in north-central, the zone that received highest budgetary allocation (south-south) only recorded 64% of poor, 59% and 67% were recorded in south-west and south-east respectively.

Figure 4. Poverty level by geo-political zones (2010)

Source: own calculations based on NPC, 2012.

The poverty situation prevailing in the geopolitical zones is serious issue and no doubt it poses challenge to the existence as one entity which often adversely affecting national development. It is on record those geopolitical zones with high severity poverty turn into “no go area” to investors as a result of crisis, notably among which is Boko Haram insurgents, to mention but a few. Scholars are of the opinion that Boko Haram crisis was second best predicament since political independence of 1960. Meaning that after civil war of early 1960s there were never major bad omen affecting peaceful coexistence as Boko Haram crisis, superseding the militant struggle in the south-south zone whom are now enjoying amnesty.

Conclusions

This study examines the relationship between equality-based budgetary allocation and the level of poverty in Nigeria. It was found in this paper that successive revenue allocation formula led to skewed budgetary allocation which causes unbalance development, poverty, and insecurity in northern part of the country. The paper concludes that time is ripe for Nigeria to

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

adopt a performance-based revenue allocation in order to minimise waste associated with the equality-based allocation. Therefore, for Nigeria to achieve holistic and sustainable national development, market forces must be allowed to allocate resources freely. Specifically, we recommend for the adoption of New Equitable Empowerment Framework whereby priorities would be placed on the untapped resource in the other areas (state) excluded from derivation with objective of augmenting their budgetary allocation to gauge them on the similar finance strength with states enjoying more of the national pie.

Keywords: *fiscal policy; general grants; European Union; central government expenditures; public finance*

Abstract: Fiscal policy, including its expenditure aspect, is often discussed and analysed from a variety of angles in the literature on public finances, undoubtedly due to the major importance of this topic. However, not all areas of the expenditure part of fiscal policy have been subjected to in-depth analysis. One of the less discussed tools of fiscal policy consists of general purpose transfers, which are a certain type of expenditure passed from the central budget to local governments. This study focuses on presenting the systems for subsidising sub-national governments in selected European countries and evaluating, based on a synthetic measure, the fiscal policies of France, Italy, the Netherlands, Lithuania, Poland and Finland implemented by means of general transfers, with the aim of identifying the best fiscal policy with respect to subsidising and the characteristic features determining its success. The method of unitisation of statistical feature values was employed in this study to enable comparative analysis. As suggested by the results of the analy-

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

sis, spanning the years 2003–2012, the highest-ranked fiscal policy implemented via general-purpose transfers has been developed in the Netherlands.

Introduction

As one of the types of expenditures financed by the state budget, general grants are a tool of fiscal policy that varies greatly from country to country in terms of the manner and extent of application. This can be explained by the fact that while European Union regulations are uniform with respect to such fiscal policy tools as budget deficit and public debt, the member states are not restricted by them when it comes to structuring the state's expenditures. What is more, the scope and principles of awarding general grants as one of the sources of funds for local governments in the individual countries result from their independent decisions concerning the preferred extent of decentralisation and division of public revenues between the central and sub-national level. The main aim of this study is to present the subsidising systems and evaluate the fiscal policy implemented via general grants in six selected European Union countries – France, Italy, the Netherlands, Lithuania, Poland and Finland (chosen because of their diverse systems of organisation of state authorities, local governments and public finances) in order to identify the best system and, on this basis, the desirable features of such transfers. In order to capture the effect of any changes to the rules governing the award of general grants and to enable a more comprehensive assessment of fiscal policy in this respect, a ten-year period between 2003 and 2012 was considered in the study. To enable comparative analysis, the method of unitisation of values of specific statistical features was employed. A synthetic indicator was thus obtained to rank the fiscal policy pursued by the individual states via general grants and to identify the best one.

Subsidies for local governments in contemporary fiscal policy

Fiscal policy and monetary policy constitute parts of the state's financial policy, understood to mean conscious and purposeful activities of persons and institutions that include establishing and achieving specific goals via financial means (measures, actions). Its essence is the ability to collect and spend public funds to achieve objectives of both social and economic nature (Kosikowski, Ruśkowski, 2008, p. 33). Nowadays, it is expressed by the economic programmes for future periods, adopted by public authorities

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

(Chojna-Duch, 2010, p. 44). Since fiscal policy is an inherent part of the financial policy followed by the state, it should pursue the same goals, in particular, achievement of a high level of use of the productive capacity, stabilisation of the fluctuations arising from the economic cycle by stimulating and reducing demand in the economy, creation of favourable conditions for making financial savings through optimisation of the tax burden, offsetting excessive inequalities in the division of revenue between members of society, or curbing unemployment and supporting job creation. Specific fiscal policy tools, including taxes and other public charges, expenditures, budget deficits, public debt and the guarantees issued, should contribute to the accomplishment of such objectives (Owsiak, 2002, p. 279). Although specialist publications stress that the primary general purpose of fiscal policy is to provide the state (or public authorities) with non-returnable financial resources enabling it to fulfil their duties, according to a more frequently expressed view, public expenditure is also a very important instrument of fiscal policy (Ferreiro et al., 2012, p. 652; Owsiak, 2005, pp. 359-361; Palley, 2009, pp. 321-322; Sekuła, 2011, pp. 209-210; Szarowská, 2011, pp. 170). Academically, the concept of fiscal policy is usually considered equivalent to budgetary policy. It is a commonly accepted view that it encompasses both budgetary revenues and expenditures (of central and local governments) and non-budgetary ones, and in the area of expenditure it is expressed by the right, from the viewpoint of socio-economic objectives, choice of directions and the method of their implementation (Pietrzak et al., 2008, p. 290). The literature also quotes studies focusing on the expenditure aspect of fiscal policy and highlights the effect of decisions and actions taken by European Union member states on GDP growth and the unemployment rate. The states pursue their individual, quite freely structured fiscal policies with respect to expenditure, therefore achieving different effects. That is because expenditure is not governed by community regulations, which lay down strict rules as to the budget deficit and public debt (Krčílková, Antoušková, 2009, pp. 343-348).

General grants, an important source of funds enabling local governments to fulfil their duties, constitute a part of state budget expenditures and as such should be considered a tool of fiscal policy. The size of general-purpose transfers and their share in the general structure of expenditure at the central level or GDP depend on the model of public finances adopted in a particular country and the degree of their decentralisation. In view of the fact that decentralisation is a dynamic process increasing the scope and variety of tasks carried out by local governments, it leads to continuous

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

enhancement of the allocation and redistribution functions performed by local finances. This trend is associated with the principles of adequacy and subsidiarity formulated in the European Charter of Local Self-Government, resulting in the necessity of supplementing local government's budgets with funds from the state budget. Establishing the right level and form of this support is becoming an increasingly important issue of state fiscal policy (Guziejewska, 2007, p. 71). On the whole, from the point of view of financial independence, general grants are the preferred type of revenue of local governments as they ensure freedom of choice as to the allocation of expenditures. By contrast, the manner of use of specific grants, an alternative means of supplementing the budgets of local governments from the state budget, is determined by the socio-economic policy pursued by the government and therefore constitutes a more convenient and strictly controlled fiscal policy instrument. An important matter from the point of view of flexibility of transfers from the state budget is how to define the rules of the grant awarding process. The less precise they are, the easier it is to reduce and increase the amount of transfers, treating them as a discretionary tool of fiscal policy (Sekuła, 2009b, p. 756). Funds transferred from the state budget to local governments according to objective and legal criteria, as in the case of general grants, perform a stabilising role in the business cycle. But in the case of this type of transfer it is still possible to take decisions at the central level, resulting in their significant increase or decrease.

Focusing on general grants as a fiscal policy tool, it should be emphasised that it is an essential source of funds for local governments, making it possible to offset the differences in the revenue-generating potential and reduce the disparities in the spending potential of local government units. Thus, general grants enable the redistribution function, as well as allocation of funds at a higher level. They generally result in an increase of expenditures made by local governments, but they should not have an impact on the trends of spending of their funds.

Although state budget expenditures in the form of general grants constitute an element of fiscal policy and an issue of major importance due to their size and share in the general structure of central level expenditure, they have not been given sufficient attention in Polish or foreign literature. Meanwhile, the problem of utilising general grants as a source of funds to finance local governments' tasks, their share in local authorities' revenues and the consequences of utilising this form of budget revenues has been widely discussed. Similarly, specialist literature devotes much attention to fiscal policy implemented via budget expenditures analysed from a variety

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

of angles. Mainly, however, researchers focus on the changes in the size and structure of public expenditures in various phases of the economic cycle (Szarowská, 2011) and demonstrate that some of them fluctuate more strongly over time (Lane, 2002). Other issues generating considerable interest relate to the relationship linking the size and structure of budget expenditures with election cycles (Schuknecht, 2000; Efthyvoulou, 2011). As a fiscal policy tool, budget expenditures, with account taken of their variety and preferred type, are also evaluated with respect to their impact on macroeconomic quantities, such as GDP (Gupta et al., 2005) and unemployment rate (Krčílková, Antoušková, 2009). Nevertheless, researchers usually focus on the directions of expenditures and support for specific areas of public services. Sometimes only one selected type of budget expenditure is analysed (usually investment expenditure) and evaluated in terms of its impact on economic growth (Ocran, 2009). However, expenditures financed by central budgets in the form of general grants, which are an important element of fiscal policy, do not receive sufficient attention – hence the need to fill this gap and give appropriate importance to the issue of subsidisation in the context of implementation of a state's fiscal policy.

**Description of subsidisation systems in Italy, Finland, Lithuania,
the Netherlands, France and Poland**

Determination of the directions and methods of spending of collected funds is an inherent part of fiscal policy. From the state budget level, some of them are transferred to the regional and local government level. Their size and transfer rules and procedures depend on the political system in a particular country, the degree of decentralisation and the resulting system, tasks and sources of revenue of the local government. It is also formally required that delegation of specific tasks to the sub-national level should be accompanied by appropriate partial decentralisation of public revenues and expenditures. Since this requirement is impossible to meet with respect to all local government units, the state budget supports the sub-national government by means of transfers, following specific rules, differing from country to country.

Italy – one of the founding Member States of the European Union – is among the more highly populated countries in Europe. The territorial division of the country is organised into three tiers. The sub-national government system consists of 15 regions with an ordinary status, 5 regions with a special status, 102 provinces and more than 8000 municipalities. The re-

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

gions enjoy a high degree of autonomy even though Italy is not a federal state.

The basis for financial support of the sub-national government is defined in Article 119 of the Constitution of the Italian Republic, providing for an equalisation fund without restrictions in respect of the allocation of financial resources, for the territories characterised by a lower per-capita taxable capacity. It can therefore be said that the Constitution introduced the principle of balanced development of regions while empowering the state to subsidise the local government units that need support.

In practice, the principle of adequacy was initially not followed with respect to the Ordinary Statute Regions (OSRs). As recently as in the early 1990s, OSRs had virtually no independence, with up to 95% of their expenditure being financed by central government transfers. Nearly all of these grants were conditional, which means that the central government dictated the terms of use of the resources. Furthermore, the fund spending procedures were highly specific and hedged with multiple restrictions. The resources thus obtained were chiefly spent on the health service. To improve this situation, a number of decisions were taken regarding the regions' revenues, with the aim of increasing their autonomy. As a result, the share of expenditure financed by transfers dropped to 48%. After the reform, the present grant award system employs a more general formula, including analysis of expenditure needs (like in Australia) in addition to calculations based only on the revenue-generating or taxable capacity (like in Canada). The amount transferred to a particular region is the difference between the VAT amount allocated according to the equalisation formula (EVAT) and the VAT amount apportioned to the region based on the estimated consumption by its inhabitants. While there is a certain likeness to the German system in terms of calculation of equalisation transfers, such as using the share in VAT, reference to the fiscal capacity and implementation of horizontal equalisation, the Italian system differs significantly from its German counterpart. In the German system, the purpose of horizontal redistribution is only to equalise the fiscal potential of the constituent states, while the Italian system provides for the needs and costs with respect to health service and the differences in the costs of public service provision. The equalization formula introduced in Italy does not ensure matching a specific level of taxable capacity, so per capita taxable capacity can differ from the mean by more than 10% (Arachi, Zanardi, 2004, pp. 327-330).

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

Another country under discussion is the Republic of Finland. The basic issues concerning the local government system are regulated primarily by Article 121 of the Constitution of Finland.

In 1960–1980, the period of construction of the Nordic welfare state, municipalities in Finland were assigned a number of new responsibilities. The system of grants as a means of support played a crucial role in the development of the welfare state. Such a system was necessary in order to equalize the municipalities' capacity to introduce new statutory services while maintaining the local taxation at acceptable levels. This was achieved, *inter alia*, by employing categorical grants, awarded under the supervision of central government bodies, as well as specific standards stipulating the manner of management of the tasks for which the grants were awarded. At the same time, the municipalities' self-sufficiency was restricted by this change despite their extensive formal independence and fiscal autonomy of the sub-national government in terms of revenue. This autonomy was expressed by the municipalities' right to levy a tax on personal income without any limitations in terms of tax rates, personal income tax being the major source of revenue for municipalities, beside grants. Until 1993, more than 90% of grants were of the specific matching type, aimed in particular at such areas as education, social assistance and healthcare. The types of expenditures qualifying for support were precisely specified by provisions of the law. Not all expenditures were co-financed by the state, even if they were associated with a particular task. Since 1969, the grant rates have been determined according to a multi-criteria capacity classification system, categorising municipalities with respect to their demand for state support. The main classification criterion was the tax base per capita (weight of criterion: 50%). The other criteria included: net charge for the performance of obligatory tasks, poor financial situation of a municipality, certain unfavourable structural factors, such as a dispersed population, or structural changes, e.g. a high unemployment rate. Based on these criteria, an annual classification of municipalities was prepared. Those in the first class received the highest (in relation to the costs) percentage rate of support, while municipalities that fell into the tenth class were awarded the lowest percentage rate of support. The classification system was completely abolished at the beginning of 1996 to be gradually replaced, starting from 1993, by a system based on general grants and non-matching sector grants. The reason behind the reform was the wish of municipal authorities to achieve a greater independence and freedom of decision-making. The new system reduced the sector control over municipali-

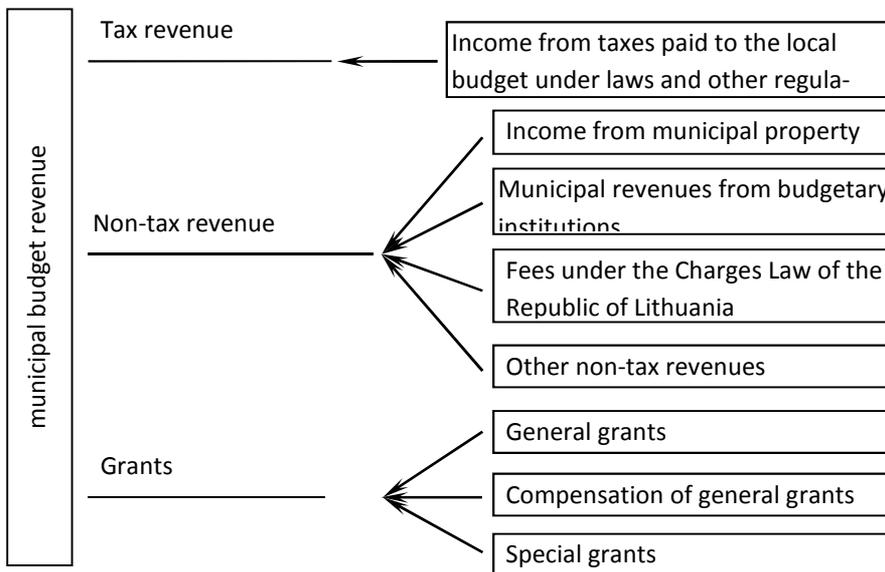

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

ties and gave them greater autonomy in the provision of services. At present, general grants consist of three parts, the first of which is based on the population criterion, the second is a supplement calculated on the basis of income tax, and the last is of discretionary nature. The two types of sector grants, i.e. for social assistance/healthcare and education/culture, are of non-matching and general nature, although they are officially referred to as sector specific grants (Oulasvirta, 1997, pp. 398-400). At the national level, replacing specific matching grants with general non-matching grants facilitates coordination of the economic policy by the government. Compared with the previous system, the new one makes it easier to reduce the aggregate amount of grants. Wishing to avoid serious political consequences (loss of votes), politicians at the national level are inclined to shift responsibility for unpopular decisions involving expenditure cuts onto the sub-national government and local politicians. On the other hand, local governments enjoying autonomy at the time of recession have the power to make their own decisions concerning the expenditure cuts required by the central government (Oulasvirta, 1997, pp. 412-413).

Another country, the Republic of Lithuania, has a relatively new sub-national government system, created after 1990. The Lithuanian self-government was developed with the objective of supporting and boosting the independence of municipalities by increasing their competences. Putting this idea into practice has given rise to problems with funding. These issues are particularly complicated because of the strongly diversified potential of Lithuanian municipalities, leading to unequal opportunities to generate revenues and capacities of providing services to the population. These problems are partly solved by revenue transfer from the state budget in the form of grants. Due to the fact that the transfer takes place between public authorities' budgets, it is also known as the interbudgetary redistribution of funds.

The act on the sources of revenues of municipality budgets in Lithuania provides for three sources of revenues: tax revenues, non-tax revenues and grants from the state budget (Fig. 1). The first two are classified as own revenues, whereas the last type constitutes state support for performance of the municipality's tasks, with the proviso that any unused funds must be returned to the state budget at the end of the year. In terms of quantity, budgets of the Lithuanian municipalities consist mainly of tax revenues and grants from the state budget. In 2009–2013 the latter accounted for ca. 50–60% of revenues of municipality budgets.

Figure 12. Sources of municipal budget revenues of the Republic of Lithuania

Source: Ginevičius et al. (2014, p. 183).

The Lithuanian law provides that general grants from the state budget should be allocated to the following purposes:

- reducing disparities between actual and planned personal income tax receipts; the recipients are municipalities with lower actual tax receipts per capita in the previous month (relative to the average for all units);
- reducing disparities in the structure of expenditures that arise from objective (demographic, social, etc.) factors, beyond the control of local authorities.

General grants are awarded for:

- implementation of tasks assigned;
- education of children, young people and adults;
- implementation of programmes adopted by the parliament and central government.

Equalisation grants are transferred to the budgets of municipalities to compensate for the changes in their revenues and expenditures resulting from the decisions of the government and parliament (Ginevičius et al., 2014, p. 184).

The increase in inequalities between municipal revenues observed in recent years calls for a better redistribution of revenue, because it is thought

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

that the existing system of local government funding does not provide a solution to this problem.

The next country presented here, the Netherlands, is a constitutional monarchy. In respect of the position of sub-national government and its financial system in the structure of the state, the local government system in the Netherlands is characterised by a small proportion of own revenues in overall revenue and a heavy dependence of local authorities on central budget transfers. The main sources of funds for the Dutch municipalities are general and specific grants from the state budget. They jointly account for nearly 5.6% of GDP (2009), of which general grants constitute 3.1%, specific grants 2.3%, and local taxes only 0.8%. The Dutch provinces also rely heavily on general and specific grants, accounting for ca. 0.25% and 0.4% of GDP, respectively. These data refer to the national average. In some provinces, revenue from property is of primary importance, arising from ownership rights to energy companies (Bos, 2012, p. 14).

General grants are transferred to municipalities and provinces via the municipal fund and provincial fund, respectively. Their size depends on the changes in expenditure from the state budget, which means that the municipalities and provinces jointly participate in budget cuts or additional expenditure. For example, €1 billion of additional state budget expenditure translates into a global increase in the revenue of municipalities and provinces by ca. €200 million. A sample structure of municipalities' revenues is presented in Table 1.

Table 18. Size and composition of the revenue of Dutch municipalities in 2009

Type of revenue	€ billion	%	% GDP	€ thousand/ inhabitant
Transfer from municipality fund	17.7	37	3.1	1.1
Specific transfers by central government, including:	12.9	27	2.3	0.8
- Social assistance,	9.4	20	1.6	0.6
- Other.	3.5	7	0.6	0.2
Sale of goods and services	11.3	23	2.0	0.7
Taxes	4.4	9	0.8	0.3
Property income	1.9	4	0.3	0.1
Total revenue	48.1	100	8.4	2.9

Source: Bos (2012, p. 43).

Grants from the municipal fund are calculated for the individual municipalities using a complicated formula, including a number of objective criteria. The aspects taken into consideration include the size of population, taxable capacity, as well as external factors, such as the role in the region or

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

the social and material structure of the population. The indicators used in calculation of a grant are determined on the basis of formulae including, in particular, the number of households drawing welfare benefits, the size of ethnic minority populations, the number of young and elderly persons, population density and the area of the historical centre of the municipality. The grant calculated from such a formula is increased by a fixed amount for the Frisian Islands and the country's four main cities. The average general grant was ca. €1000 per capita and between €600,000 and €2,500,000 for the individual units. In practice, large municipalities receive higher per capita grants than smaller units. This is due to greater demand for social services: as demonstrated by studies, cities tend to attract lower-income persons. Equally complex formulae are used in the case of the provincial fund and specific grants (Bos, 2012, pp. 43-44).

The French Republic, in common with the Italian Republic, is one of the founding Member States of the European Union. In both these countries public task funding was initially highly centralised; its decentralisation was achieved in the course of reforms. At present, transfers from the state budget are an important and increasingly significant part of the revenue of local government units in France. In the past they used to consist largely of specific grants, but today they are subventions that can be freely disposed of by local authorities (Śmiechowicz, 2008, p. 421-422). Sub-national government revenues are mainly composed of tax revenues (50% of the entire funds) and transfers from the state budget (35%). The latter are awarded for different purposes and take on different forms. The functioning of the system is additionally complicated by the fact that the individual grants are not allocated for single, specific aims. This complexity makes it difficult to analyse the whole system. The three main targets for state budget transfers are:

1. Financing of tasks assigned to local governments. Whenever the central government sets a task for a local government unit, it also allocates funds for its implementation – from tax revenue or in the form of grants. Since public tasks assigned to the sub-national government are usually financed by transfers from the state budget rather than from tax resources, the proportion of central budget transfers in overall revenues shows an increasing trend (Jamet, 2007, p. 22). Moreover, the amount of grant is calculated from a formula at a rate more favourable than the inflation rate.
2. Compensation for tax exemptions. If the central government decides to exempt a certain group of taxpayers from a specific local tax or to re-

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

duce the tax rate, it compensates the local government for the lost revenue. Most of these exemptions apply to property tax and business tax paid annually by natural and legal persons carrying on economic activity.

3. Equalisation. The state uses transfers to reduce the disparities between local governments in their “purchasing power” defined as the expenditure to revenue ratio. The amount of equalisation to be distributed between the individual local governments is determined every year by the central government based on the indicators of their respective revenues and expenditures.

In the original system, the individual grants were linked to their specific purposes. Over time, however, when it became increasingly difficult to compensate exactly for various shifts and exemptions by means of transfers, the individual grants were combined into larger ones. The present system, which has resulted from these changes, is of an intermediate nature. It consists primarily of the general grant, referred to by the acronym DGF (Fr. *dotation globale de fonctionnement*), but individual types of grants still exist as well. DGF accounts for more than 60% of funding from the state budget and includes the transfer for all the three target areas. Local governments are entitled to use it at their own discretion. One part of the grant constitutes an amount proportional to the amounts paid the year before, depending on the size of the population and also including compensation for the elimination of the pay-related portion of the business tax in 1999. The other part is intended to promote equalisation; it depends on the deficiency of taxable capacity and tax revenue from households. It includes the urban equalisation grant, rural equalisation grant and state equalisation grant.

There are other grants beside DGF, financing the individual expenditures, e.g. the decentralisation grant – DGD (Fr. *dotation globale de décentralisation*). Financed by the central government, it has the form of a lump-sum grant. The principle of awarding DGD is that the amount of transfer should cover all additional costs incurred as a result of decentralisation of tasks, which are delegated to the regional-level governments. For example, in 2004 DGD accounted for 20% of the revenues of regions (Josselin et al., 2013, p. 325).

The sub-national government in Poland, the last country considered here, was formed roughly in the same period as the Lithuanian system: its 25th anniversary is celebrated in 2015.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

The obligatory sources of local government revenues are referred to in various Polish laws, including the most important one – the Polish Constitution. According to the division presented therein (Article 167), there are three types of local government sources of revenue: own revenues, general grants (termed general subsidies in the constitution) and specific grants from the state budget. The three different groups of revenues were designated with respect to the control of receipts and spending of funds obtained from a particular source: the extent of control is the greatest for own revenues and the smallest for specific grants. The significance of general grants is varied in the local governments budgets: the lowest in provinces (ca. 16% of budget revenues) and the highest in land counties, where they account for ca. 43–45% of revenues.

Under Polish law, own revenues include receipts from shares in personal income tax (PIT) and corporate income tax (CIT), which constitute part of the state budget revenues. This inclusion is of formal nature only, because such receipts do not have the characteristic feature attributed to own revenues, i.e. fiscal autonomy, which relates to the scope of powers to establish and control the revenues that enable a unit to manage its finances independently; in terms of autonomy, they bear the most resemblance to general grants.

The primary aim of fund transfer in the form of general grants is to supplement a particular unit's own revenues. What distinguishes them from specific grants is the freedom as to the way of fund disposal – the decision concerning the allocation of funds from general grants rests with the legislative body.

As of 2004, general grants consist of three components:

- equalisation,
- balancing (regional in provinces),
- educational.

The first and third components, i.e. equalisation and educational, are transferred from the state budget. The second one derives from payments from wealthier units and constitutes an element of horizontal equalisation of revenues.

The first component is referred to as an equalisation general grant. Its purpose is to offset the difference of revenues earned by local government units at a particular tier and to assist economically weaker units. Another component – the balancing general grant (regional in provinces) – consists of payments made by units characterised by a high fiscal capacity. Because of the method of collection and division (transfers from wealthy units to

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

poor ones), it is commonly referred to as a 'Robin Hood charge' (Polish: *janosikowe*). This type of general grant is highly controversial, not only in Poland, due to its functioning in the local government finance system and method of calculation of wealthy units' payments. Objections to the compulsory contributions to the Robin Hood charge were also raised, for example, by the German state of Hesse.

The last component of the general grant is the educational general grant. In terms of the amount it is the largest part of the general grant, especially in counties and communes. Its overall amount for all the local government units is specified by the budget act. In the case of the educational component the idea behind the solution is dubious, i.e. financing of education by means of grants. The essence of general grants is to minimise disproportions or supplement funds, rather than finance local government units' functions. Formally, it is not appropriate to link the educational general grant revenues with expenditure on education due to the features of the general grant (unspecified purpose of expenditure). This is the case in practical terms, however, due to the considerable share of education expenditure in overall spending. To emphasise this relationship, the term 'education-specific grant' is often used. Hence, subsidising expenditure on education is considered contrary to the general idea of general grants, but rationally justified.

In practice, therefore (Sekuła, 2009a: 109):

- the equalisation general grant constitutes a means of vertical division of funds between local government and the state,
- the balancing/regional general grant is a tool of horizontal redistribution between units of the same tier,
- the education general grant is an instrument for financing education functions.

Methodology of the research

In order to investigate the general grants awarded to local governments as part of the fiscal policy pursued by the state, the authors analysed the expenditure on general grants in six selected EU countries – Italy, Finland, the Netherlands, Lithuania, France and Poland – having diverse systems of organisation of central and sub-national government, different principles of division of public revenue between the central and local governments and diverse socio-economic policies and, consequently, different scopes of public expenditures.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

The fiscal policy and its effects are of long-term character. Therefore, the analyses performed as part of this study cover the data for a relatively long period of ten years between 2003 and 2012. Focusing on this period, it is possible to identify the financial effects, expressed by the size of expenditure on general grants from central budgets, of the changes introduced to the principles of subsidising local government units by the public authorities in the countries investigated.

The research was based on the data collected by Eurostat – the statistical office of the European Union – and, because of the absence of certain information relating to Poland, on *Sprawozdania z wykonania budżetu państwa (Reports on state budget implementation)* for 2003–2012. To examine the fiscal relationships between the national and sub-national government sectors in the individual states, the authors used the value of expenditures in the form of general grants transferred from the central government to local governments. Such expenditures were determined on the expenditures basis of *Classification of the functions of government, COFOG*, which classifies expenditures according to a system of divisions (functions), groups and classes. The expenditures under discussion are recorded in the *General public services* division as a group titled *Transfers of a general character between different levels of government*. The COFOG classification is based on the historical European System of Accounts – ESA 95. For this reason and to take advantage of the more comprehensive range of data concerning other quantities used in the study, i.e. the revenues and expenditures at the central level and the revenues of local governments in the countries analysed, the Eurostat data were used, collected according to the ESA 95 methodology. The quantities describing the populations of the individual countries were also obtained from Eurostat. Because of the political system of the countries investigated and the financing policies with respect to the size of general grants, this study uses Eurostat statistical data that apply to the local government level. Since the aforementioned statistics do not specify the size of general grants to the local governments in Poland, the missing data required for analysis were obtained based on *Sprawozdania z wykonania budżetu państwa (Reports on state budget implementation)* and converted into EUR using weighted average EUR exchange rates for the respective years.

Structuring budget expenditures is one of the aspects of fiscal policy. As previously mentioned, these expenditures include the amounts transferred from the state budget in the form of grants for local governments. In order to evaluate the fiscal policy pursued by the aforementioned countries with

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

respect to the structure of expenditure for grants, the authors employed the method of unitisation of values of the statistical features included in the study to enable further comparative analysis. The normalisation procedure transforms the data to enable calculation of a synthetic indicator, which is the arithmetic mean of all variables, assuming values between 0 and 1 after conversion. It is performed for each feature separately, in a slightly different manner for positively and negatively correlated explanatory variables, in accordance with the following formulae:

$$z_s = \frac{x - \min x}{\max x - \min x}; \quad z_d = \frac{\max x - x}{\max x - \min x}; \text{ where:}$$

z – normalised variable,

s, d – positively and negatively correlated explanatory variables, respectively,

x – value of the analysed feature for a particular country,

$\max x, \min x$ – maximum and minimum values of variable x .

Five variables were used in this study:

x_1 – size of transfers of a general character from the state budget to local governments (€ million/resident) – positively correlated explanatory variable,

x_2 – size of transfers of a general character from the state budget to local governments relative to state budget expenditure (%) – positively correlated explanatory variable,

x_3 – size of transfers of a general character from the state budget to local governments relative to state budget revenue (%) – positively correlated explanatory variable,

x_4 – size of transfers of a general character from the state budget to local governments relative to overall revenues of local governments (%) – negatively correlated explanatory variable,

x_5 – size of transfers of a general character from the state budget to local governments relative to local governments' property income (%) – negatively correlated explanatory variable,

The choice of variables reflected the purpose of the study (expenditure on general grants as part of the state fiscal policy) and the availability of data on the Eurostat website.

Size and importance of state budget expenditure on general grants for local governments in selected EU countries

In order to normalise quantitative features, they first need to be collected and summarised. The data for variables x_1 – x_5 are presented in Tables 2–6.

The size of transfers from the central budget to local governments varied greatly between the countries analysed (Fig. 1). This is not surprising in view of the diverse capacity of public finances, influenced by a number of factors (area of the country, population size, GDP generated). Interestingly, however, the size of general grants changed in a variety of ways in the individual countries over the period investigated.

Figure 1. General grant amount in 2003–2012 in € million.

Source: own calculations based on Eurostat, Ministry of Finance data.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

The general trend (Fig. 1) shows an increase in this type of expenditure in the central budgets in the majority of the countries, most significant in the Netherlands. However, it can be observed that in one of the countries – France – the size of general grants at the end of the period analysed was lower than in 2003, although France is the country with the highest expenditure on local government financing in the form of general grants. It is worth emphasising that the size of fund transfers varied significantly in that country from year to year and accounted for a smaller share of overall central budget expenditure than in e.g. Lithuania, Poland, the Netherlands or Italy (Table 3).

Meanwhile, the importance of the general grant as a type of expenditure financed by the central budget increased markedly in Italy, where general purpose transfers from the state budget to local governments accounted for a mere 5% of the overall expenditure in 2003 to increase more than twofold ten years later (Table 3). By comparison, Finland maintained a stable expenditure policy in that period. While the proportion of expenditures in the form of general grants increased by more than 1 percentage point in the period examined, in 2012 they still accounted for less than 6% of the central budget expenditure and were the lowest both in absolute terms and as a share in the central budget expenditure among all the countries analysed. General grants were the heaviest burden for the central budget of Lithuania (accounting for 23% of the expenditure in 2010), although in absolute terms they were the lowest among the countries investigated. At the same time, the data contained in Table 4 suggest that general grants absorbed a far greater proportion of state budget revenues than similar transfers in other countries investigated; this proportion was the lowest in Finland, where such grants accounted for only a small share of central budget expenditure.

By analysing the size of general grants per resident and their share in the revenues of sub-national governments, it is possible to evaluate this type of local government revenue as the source of financing of its tasks. As indicated by the data in Tables 2 and 3, the Dutch local governments received the most funds per resident – these amounts were more than four times as high as in Poland, where the amount of general grants per capita was the lowest, despite increasing steadily. The size of this type of transfer was quite similar in Lithuania and Finland. Far greater values were observed in France and Italy. What is worth mentioning, the extreme values – the highest for the Netherlands and the lowest for Poland – were widely different from the arithmetic mean of nearly €700 per capita in 2012.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

Analysis of the data presented in Table 5 also shows the sharp contrasts in terms of the importance of general grants as a source of revenues of local governments in France, Italy, Lithuania, the Netherlands, Poland and Finland. In Lithuania such grants played a key role in the financing of local government units, ranging between 39% and 53% of their revenues, whereas in Finland it was just a supplementary source of funds of almost marginal importance, accounting for 6–7% of local government revenue. However, in most of the countries under consideration, general grants are an important but not principal means of meeting the expenditures incurred by the sub-national level of government. Any changes in the calculation procedures resulting in an increase or reduction of the amounts transferred from the state budget are directly reflected in the scope of the financed local governments' expenditures.

The data contained in Tables 2–6 were normalised using the formula presented in the section devoted to methodology. The results of this procedure are shown in Table 7.

Based on the selected methodology and the variables used in the study, with respect to fiscal policy carried out by means of general grants for the local government, the Dutch system was given the highest rating. As regards one of the variables – the size of transfers per capita – the values were the highest among the countries under discussion. In the case of two other variables, expressing the share of general grants in the revenues and expenditures of the state budget (a measure eliminating the effect of the country's wealth on the size of general grants), Lithuania was a clear leader. The figures for the Netherlands were average in this respect.

Table 7. Normalised values of measures included in the study

variable	x_1	x_2	x_3	x_4	x_5	mean
France	0.56	0.45	0.52	0.57	0.46	0.512
Italy	0.34	0.20	0.22	0.80	0.80	0.472
Lithuania	0.11	1.0	1.0	0.0	0.0	0.422
Netherlands	1.0	0.49	0.45	0.63	0.88	0.690
Poland	0.0	0.57	0.65	0.55	0.73	0.500
Finland	0.18	0.0	0.0	1.0	1.0	0.436

Source: own calculations

The next two variables are negatively correlated explanatory variables. It was assumed that the right solution involves high general grant amounts, hence x_1 – x_3 as positively correlated explanatory variables; on the other hand, general grants are not meant to replace own revenues, so their share

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

in the revenues of local governments should be of supplementary character, with the greatest emphasis on own revenues characterised by extensive fiscal autonomy, represented here by property income. In the case of two variables (x_4 and x_5) Finland is an undisputed leader, although the Netherlands, despite the common opinion concerning low receipts from own revenues, is ranked only worse than Italy but better than e.g. France.

The low rank of Finland, a country whose local governments enjoy considerable independence and a wide range of own revenues, is due to the fact that the receipts from own revenues cannot be considered an instrument of fiscal policy since they do not pass through the state budget.

With the lowest amount of general grants per capita, Poland was third in the final ranking – behind the Netherlands and France.

Conclusions

This study, devoted to the topic of general grants as a tool of fiscal policy, fills a gap in the literature on public finances. The results of the analysis conducted indicate that although the size and scope of general grants are very different in the individual countries in absolute terms, in per capita values and expressed as a proportion of the central budget and local government revenues, this means of support was an important instrument of fiscal policy in all the countries analysed, i.e. France, Italy, the Netherlands, Lithuania, Poland and Finland, accounting for between nearly 5% and nearly 20% of the central budget expenditure. Simultaneously, using the method of unitisation of the statistical features included in the study, a comparative analysis of fiscal policy conducted via general grants was performed to create a ranking of countries, where the policy of the Netherlands was ranked the best and that of Lithuania the worst. By applying the aforementioned method it is possible to formulate recommendations concerning the structure of general grants based on the model of the country that received the highest ranking. The results obtained may contribute to further, extended studies of the fiscal policy implemented in the form of general grants with respect to both territory and the range of variables included in the analysis.

Energy security of Ukraine in the Context of its Sustainable Development

JEL Classification: *F5; O20; Q01; Q4; Q5*

Keywords: *energy security; fuel and energy resources; sustainable development; energy efficiency; energy consumption*

Abstract: Energy security is an important issue for Ukraine's sustainable development. The main goal of the article is to show the state of energy security of Ukraine, analyze its tendencies and challenges, reveal the impact of energy security on sustainable development of a country. The state of the energy security of Ukraine was analyzed with the help of data collection, processing and analysis. Data was taken from State Statistics Service of Ukraine, Ministry of Energetics and Coal Industry of Ukraine, other sources, and analyzed with the help of tools of statistics and economic analysis.

Ukraine, being a developing country and experiencing war, political and economic crisis, struggles for energy security support. The present state of energy availability and consumption in the country influences its sustainable development and political stability, and is a significant restraint in country's survival. Despite the fact, that Ukraine has enough resources' deposits to provide itself with energy, it provides less than 50% of own demands and is dependent on Russia's resources.

Production of energy in Ukraine is decreasing, but energy consumption remains high. Ukrainian industries are energywasteful and energy inefficient; the country has the leading positions in energy intensity of GDP. The article shows relation of energy sources and energy security of Ukraine to sustainable development, reveals dependency of Ukrainian energy security and indicates its main threats and ways out.

Introduction

Energy security is an important issue in development of every country and is an important constituent of a country's overall security. Energy resources of a country represent all its various resources, which are available for industrial and household usage. Energy security and energy usage trends define the technological development of a country, influence its overall performance and reveal the level of its sustainable development. Ukraine, being a developing country and experiencing war and subsequent political and economic crisis at the moment, struggles for energy security support. The present state of energy availability and consumption in the country influences its sustainable development within the limits of all three constituents: economic, ecological and social. Besides, the political stability of the country's substantially depends on energy security as well. Thus, the problem of energy security in Ukraine may become a significant restraint in country's survival and development. Therefore, the main goal of the research is to show the state of energy security of Ukraine, analyze its tendencies and challenges, reveal the impact of energy security on sustainable development of a country.

Methodology of the research

The state of the energy security of Ukraine was analyzed with the help of data collection, processing and analysis. Data was taken from State Statistics Service of Ukraine, Ministry of Energetics and Coal Industry of Ukraine, reports and researches of other governmental and local departments and NGOs, and analyzed with the help of tools of statistics and economic analysis.

Ukraine is a country, which has deposits of all kinds of fuel and energy resources (natural gas, oil, coal, peat, uranium and others). However, present resources' reserves and the amount of their extraction are not enough for provision of Ukraine with the necessary amount of the fuel and energy, and thus do not guarantee the level of country's energy security (State Geological and Mineral Resources of Ukraine, n.d.).

Ukraine provides only about 47% of its demands with own fuel and energy resources (State Geological and Mineral Resources of Ukraine, n.d.). The main resources, extracted by Ukraine, are coal and peat, natural gas, crude oil, uranium (State Geological and Mineral Resources of Ukraine,

The structure of final consumption of energy resources in Ukraine is presented on figure 1.

Of all the consumed resources, natural gas has the leading position in final consumption (with share of 36.39%), while crude oil is the least used source of energy (with share of only 0.01%). Biofuel and waste remain not a popular energy source in Ukrainian consumption with a share of 1.41% in the total energy consumption. Oil products, coal and peat, heat energy and electrical energy have approximately the same shares, which vary from 13.14% to 16.63%. It is necessary to note, that atomic, hydro, wind and sun energy (which are listed as the sources, used in Ukraine, but are not represented on the graph at figure 1) are used mostly for production of heat energy and thus are not a source of energy for final consumption, but are resources for intermediate consumption.

18-19 June 2015, Economics and Finance**

Figure 1. Structure of final consumption of energy resources in Ukraine

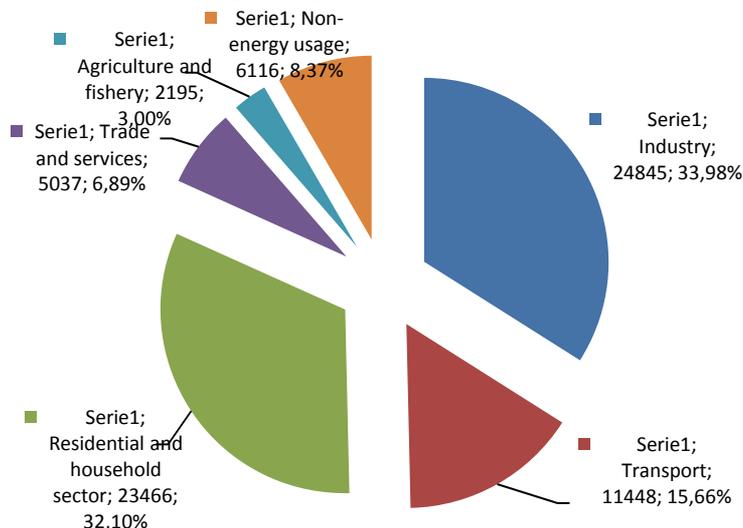

Note: the numbers, which represent consumption of resources, are measured in thousand TOE (tons of oil equivalent)

Source: created by author, using data in (State Statistics Service of Ukraine 2013 *Fuel and Energy Resources of Ukraine*)

Pattern of energy usage in 2012 (figure 2) shows that industry and residential and household sector consume the majority of energy resources (33.98% and 32.10% respectively). Agriculture, trade and services require minor energy costs. Transport consumed 15.66% of all energy resources (74% of the "transport energy" was consumed by automobile transport). Trade and services required only 6.89% of all energy consumed in Ukraine. Share of agriculture and fishery was only 3%, among which almost all the energy was consumed by agriculture with the exception of 11 thousands TOE (which is only 0.5% of all the energy consumed by this sector). Non-energy usage includes usage of energy resources mainly as raw materials. Its share in total consuming of energy resources was 8.37% in 2012 (State Statistics Service of Ukraine, 2013, *Energetychni balans*).

Figure 2. Pattern of energy usage in Ukraine in 2012

Note: the numbers, which represent consumption of resources, are measured in thousand TOE (tons of oil equivalent)

Source: created by author, using data in (State Statistics Service of Ukraine, 2013, *Energetychnyi balans*)

Coal is the main energy resource of Ukraine, which significantly supports its energy security. Deposits of coal in Ukraine amount 7.5% of world deposits, placing the country among the top 5 countries with the largest coal deposits (after China, the USA, India and Russian Federation) (SSIE "Geoinform Ukrainy", n.d.; State Geological and Mineral Resources of Ukraine, n.d.). The amount of coal, extracted annually in Ukraine, makes about 1.5% of world extraction. Luhansk and Donetsk regions produce 70% of Ukrainian total coal (43% and 27% respectively) (*Vydobutok vugillya v Ukrayini nyni vedetsya v 160 shahtah. Infografika*, 2013).

Production of coal in 2014 was 22% less than in 2013, and 24% less than in 2012. Such significant decrease can be explained by the antiterrorist operation, which started in 2014 in Luhansk and Donetsk regions of Ukraine and continues in 2015. Consumption of coal also decreased, however, the rate of such decrease differs from the rate of production decrease (16% less in 2014 compared to 2013).

Natural gas remains an important energy source in Ukraine. However, the country cannot provide itself with the necessary energy. Russia is the main importer of gas into Ukraine. In 2013 Russia provided 25.8 bln cubic

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

meters of imported gas (or 92% of total imported gas) to Ukraine, which is nevertheless 15.1% less than in 2012 (*Ukraina v 2013 godu importirovala gaza na 12 mlrd doll*, 2014). In 2014 Ukraine reduced import of gas from Russia down to 14.5 bln cubic meters (which is 1.8 times less than in 2013), and increased import of gas from EU by 2.4 times (from 2.1 bln cubic meters to 5 bln cubic meters) (*Ukraina v 2014 godu pochti v dva raza sokratila import gaza iz Rossii i uvelichila iz ES*, 2015).

75.5% of total potential hydrocarbon (gas and oil) resources is deposited overland, while 24.5% is on shelf of the Black and the Azov Seas. Ukraine takes the third place in Europe (after Great Britain and Norway, excluding Russia) by oil deposits, however, oil extraction is much less than in specified countries and many other European and non-European countries (State Geological and Mineral Resources of Ukraine, n.d.).

Extraction of natural gas and oil also decreased in 2014. As some of the sources of these resources are on shelf of the Black and the Azov Seas, this was also influenced by annexation of Crimea by Russian Federation in 2014.

In 2014 the amount of consumed oil products was 5.6 times more than the amount of produced oil products. This relation increases with every year, despite the fact that Ukraine reduces the amount of consumed oil products annually: in 2014 the amount of consumed petroleum, diesel fuel and masut decreased by 15% compared to 2013, and by 19% compared to 2012. The amount of produced petroleum, diesel fuel and masut was reduced in 2014 by 39% compared to 2013, and by 59% compared to 2012.

Ukraine extracts about 500-800 tonnes of uranium annually, which provides only 30% of the country's atomic energy needs. The rest of required uranium is imported mainly from Russia (Website on Nuclear and Radiation Safety and Non-Proliferation, n.d.; Pavlenko, 2014). Ukraine has 4 nuclear plants with 15 power generating units in Zaporizhzhya, Mykolayiv, Khmelnytsky, and Rivne, which today work at full capacity to provide the country with the necessary energy (World Nuclear Association, 2015, *Nuclear Power in Ukraine*). Ukraine has 12 assured uranium deposits, the resources of which can provide Ukrainian nuclear plants for 100 years. The biggest deposits are located in Kyrovograd region, which is in the centre of Ukraine (Website on Nuclear and Radiation Safety and Non-Proliferation, n.d.). However, there are problems of Ukrainian uranium ore enrichment, storing and processing of waste products, maintenance and replacement of nuclear equipment and its component parts.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

According to Energy Balance of Ukraine in 2012 Ukraine also produced energy from alternative sources: wind and sun energy. The share of such energy sources in total energy resources is miserable – 53 thousand TOE compared to 122 488 thousand TOE (total produced energy) (or 0,043%). Production of energy from biofuel and waste products was 1565 thousand TOE in 2012 (or 1.28% from total produced energy) (State Statistics Service of Ukraine, 2013, *Energetychnyi balans*). State Agency on Energy Efficiency and Energy Saving of Ukraine says that "Ukraine has a considerable technically achievable potential to produce fuels from renewable energy sources and alternative fuels ... which is above 98,0 mln. tons per year" (State Agency on Energy Efficiency and Energy Saving of Ukraine, n.d., *Potential*). However, the total amount of energy, produced from sustainable sources in 2013, could substitute only 200.4 thousand tons of fuel, which proves significant underload of Ukraine's capacities. Still, the amount of sustainable energy, produced in 2013, was 1.5 times more than the same indicator in 2012 (1144.9 thousand Gcal in 2013 compared to 382.9 thousand Gcal in 2012.) (State Agency on Energy Efficiency and Energy Saving of Ukraine, n.d., *Suchasnyy stan*).

The dynamics of capacity and production of electrical energy from sustainable sources in Ukraine (table 3) shows, that these indicators grow significantly every year. The total capacity of sustainable energy sources increased in 2013 by 83% compared to 2012, and by 710% compared to 2010. The total production of electrical energy from sustainable sources increased in 2013 by 95% in relation to 2012, and by 529% in relation to 2010. These sources are registered sources, which are of state and private property and have the right to use "green" tariffs for consumption of sustainable energy.

The increase of sustainable energy sources cannot acknowledge the strengthening of energy security of Ukraine, as, firstly, the share of sustainable energy sources in total amount of sources is very small, and secondly, some of the objects of sustainable energy sources are situated in Crimea (4 sun power stations and 1 wind power station, the delivery of energy from which was stopped in April 2014) and Luhansk region (1 wind power station), part of the territory of which is not under control by the Ukrainian government (State Agency on Energy Efficiency and Energy Saving of Ukraine, n.d., *Suchasnyy stan*).

Source: created by author using data in (State Agency on Energy Efficiency and Energy Saving of Ukraine, n.d., Suchasny stan).

Production of energy in Ukraine is decreasing against the increasing world energy production (*Global Energy Statistical Yearbook 2011*). However, energy consumption in Ukraine remains high.

Energy efficiency of Ukrainian industries is backward and outdated, compared to other European countries. For example, energy costs reach 10% of all costs in metallurgical industry, and 40-70% in chemical industry (depending on the type of products). Besides, partial work load of many industrious companies influence quantity of energy costs, as they often make manufacturing overhead costs (Sukov and Kabash, 2014).

Ukrainian industries are energywasteful. Despite the fact, that energy intensity decreased significantly in Ukraine for the past 10 years, the country still has the leading positions in energy intensity of GDP among the world

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

countries (*Global Energy Statistical Yearbook 2011*; Sukov and Kabash, 2014). Primary energy use (kg of oil equivalent per capita) in Ukraine was 2,884 in 2010, and 2,766 in 2011.

**Relation of energy sources and energy security of Ukraine
to sustainable development**

Energy security and development of energy sector in a country are directly connected to all constituents of its sustainable development: economic, ecological and social. Provision of access to energy sources, improvement of energy consumption, increase of sustainable energy sources are the goals of UN Initiative "Sustainable Energy for all", which are planned to be reached by 2030 (United Nations, n.d.).

Developed energy sector and, as a result, stable energy security attest development and stable work of industries in a country, provision with necessary energy resources industries and household sector, and thus influence economic development of a country.

Economic development of a country is connected with income of population, availability of goods and services, purchasing power. Stable supply of energy for needs of population reflects satisfaction of people's basic needs and rights, standards of living, social and human development of country's population.

Development of energy sector in a country may lead to environmental problems, as energy factories and plants are real and potential sources of pollution. As an example, accident on Chernobyl atomic energy station in 1986 significantly influenced environment and people's health.

According to analyzed data (tables 1-3), Ukraine's energy sources cannot be considered sustainable, as extraction of resources and industries' performance are accompanied with ecological and social problems, power loss and resources waste.

Coal, being the most significant source for Ukrainian industries, is not a sustainable energy source. Coal mining is a source of the range of ecological problems in Ukraine, among which are the following: air pollution, change of geological, hydrological and hydrochemical state of the territories, on which the coal producers operate (Ogarenko, 2007). Earth surface slump, underflooding, change of mesophytic plant formations, mineralization of water-bearing stratum and soil take place in the areas, where coal mines are situated. These changes lead to consequent damage of buildings, constructions and communications, make soil and water unsuitable for in-

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

dustrious, agricultural and household usage, pollution of water and change of species. Operation of coal mines and spontaneous combustion of ore residues emit carbon and sulfur dioxide, hydrogen sulfide, nitric oxide into atmosphere. The operation of coal-mines leads to annual emission of 5.6 bln cubic meters of methane into atmosphere. The most polluted regions in Ukraine are Luhansk, Donetsk, Dnepropetrovsk. One spontaneous combustion of disposals can emit 150 tonnes of carbon dioxide, 1.5 tonnes of sulfur dioxide, 0.4 tonnes of hydrogen sulfide, 0.1 tonnes of nitric oxide for 1 day into atmosphere (*Osnovni Problemy Rozvytku Vuhil'noyi Haluzi i Rehionu Donbasu*, 2002).

Coal industry has the leading position in traumatism and mortality among other industries in Ukraine. Every mined ton of coal takes lives of 2 miners (for comparison 1.1 in Russia and 0.03 in the USA). Besides, there are a lot of illegal mines, which, first of all, lack safety engineering, secondly, illegally use labour force and underpay workers, thirdly, illegally extract natural resources of Ukraine (Makogon, 2008).

Extraction of gas and oil is also connected with environmental and economic problems. The environmental effects of gas and oil extraction deal with water and soil pollution. Examination of pollution processes showed that about 60% of groundwater pollution is related to accidents in waste water run and drain and well-drilling, and more than 30% of pollution is related to defects and breakage of subsurface equipment. Soil and water pollution lead to health problems and increase governmental costs for relevant programs (*Ekolohichni Problemy Naftovydobuvnoyi Promyslovosti*, n.d.).

The possibility of shale gas extraction in Ukraine brought to heated discussions about the prospects and problems of using such resource. On the one hand, Ukraine has considerable shale gas storage, which can support the country's economic security and improve its independence from Russia. Besides, the source of gas will be closer to consumers than the imported gas, and thus will decrease the final costs for its transportation and usage. The exact amount of shale gas resources has not been defined yet: the range of possible values is between 1.2 and 7 trillion cubic meters. According to (Yakusheko and Yakovlev, n.d.) Ukraine takes the 4th place in Europe by available shale gas resources, being just after Poland, France and Norway. On the other hand, shale gas extraction requires advanced technologies installation, considerable investments, and has serious impact on state of environment. The main environmental consequences of shale gas develop-

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

ment and extraction are increase of seismic activity risks, groundwater, water, soil and air pollution (Barannik, n.d.).

Some countries banned specific technologies of shale gas extraction on their territories because of possible negative environmental effects, which will affect people's health and lives (Bonine et al., 2013). However, large scale extraction of shale gas can totally change the energy map of the world. This change acquires political and economic shade, and may neglect the potential ecological problems, related to shale gas extraction (Yakushenko and Yakovlev, n.d.). Safety of technology for shale gas extraction is directly connected to its expenses. Thus, the extraction of shale gas in Ukraine should be carried out according to transparent principles and observance of all necessary safety measures.

Using atomic energy is always connected with risks for human lives and environment. One of the biggest environmental catastrophes in the whole world – the accident at Chernobyl atomic energy station – happened in Ukraine in 1986. The effects of the accident were enormous, as they irradiated thousands of people and contaminated the territories of Ukraine, Belarus, Russia, Scandinavia and parts of Europe (World Nuclear Association, 2014). The health effects were radiation sickness, rapid increase of cancer diseased (including thyroid cancer, leukaemia, etc.) among adults and children, cataracts, heart diseases, autoimmune thyroiditis and others (United Nations Scientific Committee on the Effects of Atomic Radiation, 2008).

Current environmental problems, which are related to using atomic energy, deal with nuclear waste processing. There are three types of waste, produced by Ukrainian atomic stations: gas-aerosol, thin and hard. They are processed according to specific for each type technologies (Website on Nuclear and Radiation Safety and Non-Proliferation, n.d., *Povodzhennya*). Ukraine also has some repositories for storing radioactive waste and certain amount of waste is sent back to Russia for reprocessing (World Nuclear Association, 2015). Management of radioactive waste requires significant costs, and needs constant improvement and modernization.

Non-productive and productive loss of energy and water is another problem of both: sustainability of energy sector and energy security. The loss leads to unjustified increase of energy tariffs and additional costs of the government (*Tekhnichne pereosnashchennya...*, n.d.).

Thus development of energy sector and energy security of the country are directly connected with its sustainable development. The interconnection of the three constituents are evident. On the one hand, development of sustainable energy sources in Ukraine is one of the important factors of

strengthening energy security of the country. On the other hand, strengthening energy security of Ukraine provides the ways of further sustainable development of the country, its economy and society. Besides, development of energy sector is connected with increase of resources extraction, risks of environmental pollution and human health.

Dependency of Ukrainian energy security, threats and ways out

Ukraine is not an energetically secure country. Despite the fact, that the country has all necessary resources for provision itself with necessary amount of energy, dependency of Ukrainian energy security on Russia remains significant. The reasons for energy insecurity are connected with the general problems of energy state in the country and its economic and political development.

The main threats for the energy security of Ukraine deal with external and internal factors. Internal factors are very close to the problems of other post-Soviet countries (Pluzhnik and Saprykina, 2013). External factors deal with the old energy connections, established when Ukraine was a part of the Soviet Union. Some of the threats are:

- high depreciation and obsolescence of equipment and fixed capital stocks of power engineering objects. A lot of plants and factories still use old equipment or equipment, which is set up for processing only certain type of resources. Unsatisfactory state of equipment and other assets increases costs and energy intensity of fuel and energy resources (Kasich and Yakovenko, 2013);
- energywasteful economics of Ukraine. Despite the fact, that energy intensity decreased significantly in Ukraine for the past 10 years, the country still has the leading positions in energy intensity of GDP among the world countries (*Global Energy Statistical Yearbook 2011*, Sukov and Kabash, 2014);
- instable prices for imported gas and oil (*Transatlantic energy security and the Ukraine-crisis: A blessing in disguise?*, 2014);
- absence of diversification of energy resources' import sources;
- current events in Ukraine: annexation of Crimea and antiterrorist operation in the East of the country.

Crisis in Ukraine undermined its energy security. Significant energy resources are situated on the occupied territory, which is not currently under control of the Ukrainian government. The electric stations suffer of coal deficit, as the coal was supplied from coal-mines from Donetsk and

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

Luhansk regions. Ukraine continues to deliver coal from the occupied territories, but the deliveries are not stable, and the amount of coal is less than required (*V Minenergo otchitalis o postavkah uglya iz DNR i LNR*, 2015). The coal deficit led to power cut-offs all over Ukraine and the necessity to import coal from other countries (*Zapasy uglya na ukrainskih TES umenshayutsya*, 2015). However, the coal, imported to Ukraine from South Africa according to the recent treaties, does not have the necessary characteristics and caused additional costs to Ukraine (*Ukraina neset ogromnyie ubyitki iz-za afrikanskogo uglya*, 2015).

Due to the current situation, Ukraine is also concerned about loss of potential gas deposits in Crimea and Donetsk region (shale gas deposits in Donetsk region, gas and oil deposits on Crimea peninsula) (*The energy dimensions of Russia's annexation of Crimea*, 2014; *Korysni kopalyny Ukrainy*, n.d.).

The war conflict in Ukraine may lead to gas crisis not only in the country, but in Europe as well. According to NATO reviews (*Transatlantic energy security and the Ukraine-crisis: A blessing in disguise?*, 2014; *Russian-Ukrainian-EU gas conflict: who stands to lose most?*, 2014), Russian gas company Gazprom provided Ukraine with more than half of the gas it needed, and supplied more than 1/3 of EU imported gas. Half of the imported gas to EU is going through Ukraine, which can be threatened with the escalation of the conflict. Loss of control of certain areas by Ukraine creates possible risks to energy security of other European countries, as the gas pipelines pass through that territory (Carney, n.d.). Ukraine itself struggles with paying the increased prices for gas because of the economic crisis as a war's consequence.

The main document, which set the directions of energy sector development, is Energy Strategy of Ukraine on period till 2030. It was adopted by the Cabinet of Ministers of Ukraine in 2006 and was renewed several times later. In 2013 the new Energy Strategy of Ukraine on period till 2030 was adopted, which foresees satisfaction of energy needs of the country and strengthening its economic security taking into account environmental effects of energy sector operation. The document contains information on all energy resources, their extraction and usage, suggests measures on energy saving, increase of energy efficiency, increase of sustainable energy sources' share in total amount of energy needed. Prognostic energy balance on 2030 expects increase of all resources extraction (coal, oil, gas, production of heat and water energy). The amount of sustainable energy is expected to increase by 80 times in 2030 compared to 2010 (Cabinet of Min-

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

isters of Ukraine, 2013). However, a lot of regulations of the Strategy have declarative nature and require adoption of other documents and programs. The strategy itself did not take into account the possible crisis in 2014-2015, which is happening at the moment.

State Agency on Energy Efficiency and Energy Saving of Ukraine developed National Plan of Actions on Renewable Energy on period till 2020. The main goal of the Plan is to increase the renewable energy sources and make the share of renewable energy in total amount of consumed energy 11%. The renewable energy sources, stipulated in the Plan, are biomass, wind energy station, sun photoelectrostations, geothermal energy, hydroelectric power stations (State Agency on Energy Efficiency and Energy Saving of Ukraine, n.d.).

There are also other programs and plans, which deal with energy sector and security of Ukraine. They are adopted locally in the cities or by enterprises and organizations (*Stalyj energetychnyj rozvytok*, n.d., DTEK, 2012). The measures, which are foreseen by all the programs (governmental and local) for strengthening of energy security of Ukraine (Kasich and Yakovenko, 2013), are the following: switch to alternative energy sources and/or increase of their share in total sources of energy; modernization of gas, electrical and heat systems (which will decrease the amount of energy used); development of idle gas fields; breaking up the monopoly of gas market.

Conclusions

Energy security is an important issue for Ukraine's sustainable development. The main energy resources in Ukraine are: coal and peat, crude oil, oil products, natural gas, atomic energy, hydroenergy, wind and sun energy, biofuel and waste, electrical energy, and heat energy. Ukraine's energy sources cannot be considered sustainable, as extraction of resources and industries' performance are accompanied with ecological and social problems, power loss and resources waste.

Despite the fact, that Ukraine has enough resources' deposits to provide itself with energy, the state of country's energy security is not satisfactory. Ukraine provides less than 50% of own demands and is dependent on Russia's resources. There are other threats to Ukrainian energy sector development, including current war situation and the need of restructuring.

The adopted Energy Strategy in Ukraine suggests the positive changes for Ukrainian energy sector, however, its realization is complicated with

**Proceedings of the 8th International Conference on Applied Economics

numerous external and internal factors. Structural reforms should be made in all directions of energy policy, which will help the country to resist the internal and external threats to its security. Any changes in the course of strengthening energy security of the country should be conformed to sustainable development concept regulations.

**Shared State Taxes and Tax Policy of Local
Self-governments in Connection With
Tax Morale**

JEL Classification: *H21, H23, H24, H26*

Keywords: *tax morale, legal morale, tax regime, tax system*

Abstract: Based on our assumption, tax morale significantly depends on a country's legal, historical, social and cultural background and circumstances.

In the first part of the paper, we discuss the legal dimension of the tax morale – including the interconnection of law, ethics and moral. Furthermore, we analyze the facts breaching tax liabilities under the scope of the criminal law and the actions violating the tax morale but not qualified as infringement of the criminal law.

In the second part of the paper, we provide empirical evidences which factors (e.g. personal characteristics, commitment for paying local taxes, knowledge about the distribution of paid taxes between central and local authorities, etc.) determine significantly the individual level of tax morale.

The paper discusses these complex connections either from the viewpoint of law or economics in order to find out whether it is possible to develop the tax morale of individuals, or can the legislator adequately rule the different forms of tax evasion.

Introduction

In this paper there are three equally important purposes: (1) to define “tax morale”; (2) to give an overview about the changes in the proportion of shared state taxes (personal income tax [PIT] and vehicle tax) between state and local budget since the change of regime; (3) to present the Hungarian tax morale with some actual data and to give empirical evidences in connection with individual tax morale.

My intention was that besides historical and social circumstances other factors – such as Machiavellian personality, commitment and faith to state and local government – have also very significant impact on the level of the individual tax morale.

Shared state taxes and local business taxes – declining share of local governments in the Hungarian tax system

The state has the sole right to specify and allocate state taxes, and has the right to give power for local governments to lay down the rules of local business taxes, and the state furthermore has the right to monitor the activity of local governments. So the taxing power of local governments is derived and limited by the state.

Accepting the importance and role of taxation at level of local government several alternatives may be distinguished depending on who should tax, what are the shares of tax revenue, etc. Local governments may derive revenue from local taxation by any of the following (Davey-Péteri, 2004, p. 217.):

- Laying taxes independently;
- Imposing a locally decided surcharge on a revenue laid and collected by other levels of government;
- Receiving a fixed share of state taxes collected within their jurisdiction.

Different models can be mentioned to analyse the fiscal connection between state budget and local government budget. We can mention a model in one hand, *where all incomes of local government rise from the state*. In this model only the central state tax system exists, there are no possibilities for local governments to lay down rules of local business taxes, they have no taxing power. Disadvantage of this model can be, that local government is naked, but advantage can be the better monitoring regime of state tax system, the state is able to monitor more efficiently the way of incomes in the case of local governments too.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

The second model is the *solidarity model*, the local government has taxing power, has the right to lay down the rules of taxation, but some taxes are centralized by the state budget, where the state has the sole right to decide the share of local governments for the tax incomes. One advantage of this model is that structural differences can be lower by this way, but disadvantage is, because governments – cardinally the rich governments (they have enough incomes from other sources) are not interested in increasing their incomes as a certain share will be the income of state budget.

The third model, liberal model, where local governments are free to lay down the rules of taxation, the state has no right to centralise tax incomes from the local government, the main incomes are the local business taxes for the local governments. The fiscal responsibility of local government is the greatest in this model, but one risk of this system can be the conflict between fiscal interest and economic policy of local and state authorities.

In Hungary, there is a mixed model, where the characteristics of liberal and solidarity model are being combined, certain taxes are incomes of state budget, and then the decision is for the state to allocate the tax income between the level of central and local budget. The cooperation and harmony is realised between the levels, the local governments has taxing power and besides they gain tax incomes from state budget as well (the so-called shared state taxes).

Hungary has been a pioneer in local government reform among transition economies. Through a series of legal reforms introduced since 1990, Hungary has established local governments with full autonomy, legal and regulatory framework for ensuring and tightened budget constraints by regulating municipal bankruptcy. So in Hungary after the *change of regime this mixed model is used, but the borders of the framework is continuously being modified by the state*.

Increase or decrease the autonomy of local government was the two-directional tendency since the change of regime by the state. This tendency has an effect on fulfilling task and on fiscal frame too.

As an example for this tendency we can mention the allocation of personal income tax (PIT) and vehicle tax. When personal income tax was introduced in 1987, the allocation of this tax income was very simple: it was the income of the so-called “tanács” (the forebear of local government). In 1990 there was a claim to change this allocation structure, the state had to decide two issues:

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

- How to allocate personal income tax between state and local government budget?
- Will it be still the income of the local government, or shall we introduce a quota, guarantee sufficient income for the state and local government too?

The Budget Act of 1991 (Act CIV. of 1990 on the State Budget of Hungary) introduced a different allocation system in Hungarian Law. In 1991 the local government received the income raising from paid personal income tax by local taxable person in 1989.

In my opinion local governments are able to levy taxes on unseen income and to collect these revenues in greater proportion in generally, because of e.g. the local relationships are generally tighter.

In the 90's, the proportion of shared state taxes descended, in 1993 the local governments received the 30% of PIT, while in 1998 only 20% of PIT was returned to local level. Since 2000 this proportion of local government was permanently below 10%. Since 2013 the local governments has not receive a certain percentage of PIT as earlier, only the revenue comes from the leasing of soil remains at local level.

At the beginning vehicle tax was also a shared state tax, which was collected within the jurisdiction of local governments and was the revenue of local budget. In the 90's there were different shares between local and state budget (100-0%, 50-50%). In 2015 the revenue from vehicle tax is divided between local and state budget as follows: state budget has a proportion 60%, local government's share is 40%.

Local taxes in Hungary

In Hungary the 1990 Law on Local Taxes declares the possible types of local taxes local governments may levy, maximum size of local tax rate is also set centrally. Local governments are entitled to introduce any or all of the following taxes: property tax, communal tax, tourism tax and business tax.

Property tax can be imposed on residential and non-residential buildings and plots. Local governments may decide free whether the assessment of tax burden will be area-based or value based. A value-based property tax is applied only by a few local authorities recently. *Communal tax* is levied on private residents, it is a special property tax, since it can be levied on household dwellings (owned or rented).

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

Tourism tax is one of the most conventional local taxes in Hungary, it can be levied based on turnover (per capita accommodation fee).

*The business tax*¹ is a turnover tax levied on manufacturer's and retail sales' net turnover.

What is tax morale – How can we measure tax morale?

For the question how can we define tax morale, it is impossible to give an exact answer, even if we know the diversified specialized literature. To get closer to the definition of tax morale at first we have to define ethic and morale. Ethic is a main form of social norms, a collection of accepted norms which had been accepted during more and more generations and which are synthesized on the base of common observations. In other words it is a community's judgment about what is right and what is wrong, helping to differentiate between the bad and good in the society.² The word morale comes from Latin "mos", principally meaning "will" in its objective sense, which manifests itself in ethic and in the law. In other sense it also means the will, approach and grain of the individual, of course strongly connected with habit, ethic and law.

In the specialized literature firstly Frey-Weck-Hannemann (1984) defined tax morale³ in 1984. Nowadays several publications are concerned with the question of tax morale⁴. Földes (2004) defined tax morale as a zero-sum game of dividing the contribution to the total public good between the members of society (which means particularly that any fraud on tax by one member of society cause a loss to another one).

Méder et al. (2012) define the basic problem of taxation as following: "... there is no tax paying instinct". The question of paying or not paying taxes is relatively new in our history and in this sense it differs from the other forms of cooperation in more ways. The significant problem of mak-

¹ Business tax has a dominant place in the Hungarian local tax system, it constitutes more than 80% from total local tax incomes of local governments.

² Laws and bills are in connection with ethic. Morality and legality are connected, but they are not the same. Ethic concerns people in their deepest nature, will and conscience, it is in the inside personality, which cannot be judged by court. Legality means the responsibility of law (Turay, 2000).

³ Tax evasion is usually explained by the Laffer curve, which shows income from taxes as a function of marginal tax rate. Frey-Weck-Hannemann (1984) states that tax morale is as much important as tax rate concerning tax revenue.

⁴ Tax morale is a complex phenomenon, it concerns law, macroeconomics, behavioural economics, sociology, etc.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

ing people paying taxes: the individual is unable to punish the cheaters efficiently. The isolated individual would be only able to punish the cheater if he himself didn't pay tax.

Although the definition of tax morale has been used by several authors, we can say that there is no universally accepted definition. Shadowing the situation we can say that the interpretation of more, strongly related definitions (hidden economy, informal economy, 'grey' economy, informal working) are disputed and can be separated to more branches. This is also the case for the dominant and significant factors of informal work. We can separate two main branches in the literature: according to the first, the rational estimation on the relative gain from tax fraud is the decisive (see Slemrod – Yitzhaki, 2002). The other considers the role of tax morale as a prior (see Torgler, 2003).

Earlier researches by Allingham-Sandmo (1972) and Yitzhaki (1974) consider tax evasion as gambling. They examined how much of the income is declared by people who are avoiding paying taxes at a given probability of tax evasion and at a given rate of punishment. Hungarian researches are initiated after the regime change in this area⁵. The main courses of the researches were hidden economy, norm following behaviour and the new tax system developed by the changing economic system⁶. A study from 2004 analyzes the tax obedience and the informal economy among 900 medium and large sized companies processing in light industry, building industry and trade (300 companies in each sector) for the years of 1996, 1998 and 2001 (Semjén, 2004).

We can say that the number of specialized literatures studying the measurement of tax morale is significant, too. Among these we can highlight the research of the Hungarian Central Bank. According to this examination of income tax declarations and VAT payments they conclude that the amount of rateable value lost due to tax evasion equals about one-quarter or one-third of the Hungarian annual GDP. This is considered a significant loss in international aspect, too⁷.

Some research considers the tendency of the number of enforcements in taxation as a tool of measuring tax morale. According to this, tax morale

⁵ However we should also mention the name of Schmidt, who had examined tax payers' behaviour and the causes in the 1940's.

⁶ We can mention the paper by Gergely (1998).

⁷

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

has been declined. Nowadays in Hungary approximately more than 360 000 enforcements are still in process. Furthermore debts in connection with enforcements were up to a thousand billion forints till the end of July, 2013⁸.

The third possible aspect of examining tax morale is comparing the non- or just partly tax-paying self-employed people with the employees in the same scope of activity. Among the employed people 14% are self-employed (individual entrepreneurs). They deny the plus burden of taxation and pay significantly less than the normal employees⁹.

Fazekas et al. (2010) searched the answer for the following question in their study¹⁰: to which degree does the rate of rational estimation and tax morale play a role in informal working in Hungary?

In case of examining the tax morale the implementation of game theory (running ultimatum, dictator or trust games) become more frequent. The empirical observations verify that tax morale plays an important role in tax evasion because the moral behaviour of individuals is typically not independent from the behaviour of reference groups (see Méder, 2012 and Simonovits, 2010).

The historical and socio-cultural determination of tax morale

According to our assumption, today's low Hungarian tax morale is caused by our history and socio culture. If we take a look at the first half of the 20th century, we can see the deep impression of tax evasion in society. A sentence by the attorney-general from the novel Rokonok by Móricz written in the beginning of 20th century: "In Hungary there is one significant problem, one huge problem: In Hungary people don't like to pay taxes... Nobody likes... neither me." We can see that the situation after a hundred years is the same. People think of taxation in a negative way. They don't consider this as a contribution to social welfare, but as a distraction, for which they don't receive a reward as a return. Moreover, some segments of society draw off from paying taxes totally, and put the burden on the trustworthy tax payers.

⁸ <http://vallalkozoi.negyed.hu/vnegyed/20130903-romokban-az-adomoral.html>

⁹ <http://blog.ucmsgroup.hu/az-adovaltozasok-hatas-a-az-adomoral-tekintetenben/>

¹⁰ The study is based upon a representative sample from 2008. According to their result the high probability of being caught decreases the probability of informal working; but the fear of unemployment increases this rate. The level of tax morale is in indirect relation with the unemployment rate.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

In the historical part of this study we consider the acts of economic policy only after World War II. In the next paragraphs we will examine in which system the Hungarian taxation worked during the years of socialism and what effect did this have on the morality of tax-system after changing the regime.

The effects of socialist economic policy on tax morale

Before the regime change the tax of state corporations were calculated on the bases of their centrally determined profit. The tax rates were usually progressive and if the profit of corporations had exceeded the centrally defined amount than tax rates could have been up to a 100%. With this act the system broke down the effort to improve the efficiency of corporations. Moreover, profitable corporations couldn't keep their plus to make investments or pay dividend. If the state had found that the profit exceeded the given limit they could have taken this money away immediately.

Besides corporations the income of individuals were taken into consideration, too. During the years of socialism in Hungary personal income was classified into two groups. On one hand the salary income of employees, on the other hand the income of entrepreneurs and passive income such as interest, rental and dividend. While in the first category the tax burden was low, the others suffered from high tax rates.

Progressive taxation – similarly to the regulation of corporate tax – decreased the willingness of entrepreneurship and people tended to hide their income from these kinds of activities. In this system the suppression of business income became a typical attitude in Hungary.

Taxation and tax morale after the regime change

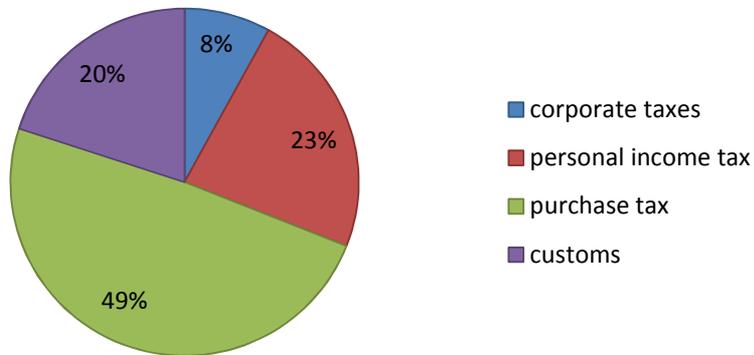

In the late 80's – short before the political change – the economy of Hungary had been radically changed. Most of all taxation was altered and re-developed on OECD practices. Market economy renewed the opportunity for people to develop new entrepreneurships and according to this, taxation on income had also been changed. After the change, both companies and individuals still had to pay their taxes in a progressive way, but there was a significant fall in the tax rates. In case of corporations before the change the rates were about 50-60%, by 1995 they were dropped to 36%. In case of individuals the marginal tax rates fell to 50%.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

Contrary to the taxation in the years of socialism, after the regime change the mechanism of self-assessment became a priority. In case of self-assessment the tax payer counts, declares and pays its tax on its own – it is a kind of voluntary way which still exists in this form up today. If we consider that before the regime change both corporations and individuals had huge tax rates on extra profit, they were interested in the suppression of their income. In the same time with the reformation of taxation-system and the significant drop of tax rates, tax payers couldn't immediately accommodate to the new system, they couldn't get rid of their habits and past experiences. In Kornai's (1990) opinion it is basically a failure to build the taxation on self-assessment among these conditions. In this environment self-assessment does not produce the real value of income tax and the state (tax authority) has to find additional information (e.g. enrichment inspect or notice from envy neighbours, etc). Finally Kornai states ironically that in Hungary, where the system is based on self-assessment, a single tax supervisor should be needed in every household, to supervise the flow of everyday income. As a solution Kornai insists on introducing impersonal taxes.

In Musgrave's (1989) works we can find a reference on the separation of personal and impersonal taxes. It states that personal taxes are those taxes which are determined on the basis of solvency of the tax payer. Contrary to this, impersonal taxes are those ones at which we don't examine the character of the tax payer. Impersonal tax is like value added tax that does not consider how solvent is the tax payer (in Hungarian we know it as general purchase tax, which is the VAT in international sense), as everyone pays by the same rate independently from how much he could pay. Moreover we consider wealth tax as an impersonal tax, which neither considers the character of the tax payer. As an impersonal tax Kornai suggested on implementing VAT at one single rate. Contrary to this, after the regime change, Hungarian tax-system relied significantly on the personal income taxes. In 1995 31% of the state tax revenues were corporate tax and income tax (see Figure 1) which shows only a minimal change compared to the data of 1986.

Figure 1. The distribution of Hungarian tax and custom revenues in 1995

Source: Hungarian Court of Auditors.

The society could not get rid of its previously fixed norms and behaviours in the first decade after the regime change and we couldn't see improvement in tax morale (Kornai, 1996).

Suggestions on improving tax morale

International experiences

It is not proven that a simple decrease of high tax rates would result in the increase of willingness to pay tax and in the raise of tax base in the short term. Although several empirical studies found positive relationship between tax burden and grey economy (e.g. Schneider, 2005), it cannot be concluded generally that decreasing the tax burden is not enough to decrease the size of informal economy, and just because of lowering tax rates tax morale won't increase¹¹. So if tax evasion is widespread, decreasing tax rates would not mean enough inspiration, even if tax evasion was inspired by high taxes earlier. Besides this, the connection between high taxes and tax evasion is endogenous which means that tax rates are high as a result of widespread informal economy. Andreoni et al. (1998) introduced softer

¹¹ Scharle Ágota (2002), Tax evasion as innovation in small businesses in Hungary, manuscript

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

definitions in connection with tax evasion like ethic emotions and the satisfaction of taxpayers with the public utilities. The authors made three important observations concerning tax morale¹²: 1. more honest citizens declare more tax; 2. tax evasion is more widespread if citizens consider taxation unfair; 3. tax evasion is more widespread if taxpayers are not satisfied with public utilities.

The effect of the structure of taxes and the focus of supervision can be both significant. On the one hand, in countries, where the rate of employees working in informal economy is significant, the tax on capital income is lower, which directly inspires the suppress of informal work. On the other hand according to OECD (2004), the problem of suppressed incomes is significantly lower in countries, where the emphasis is on the determination of corporate income instead of supervising the amount of work.

The “continuous tax reform” which means changing the rules of taxation from year to year makes an unpredictable economic environment and has a negative effect on tax morale. Closing those gaps which cause huge amount of loss in income and making administrative rules in taxation against tax evasion do not equal with tax reform. Making regulations that increase the will of taxpaying and decrease tax evasion on short term does not necessarily mean the increase of tax morale on long term, because getting acquainted with the new laws and finding new gaps tax evasion may grow again. Tax amnesties can also be easily included in expectations, decreasing further the tax morale.

When transforming the taxation system and considering its effect on tax morale and on horizontal or vertical equality, we have to take into account not only the personal income taxes but the social insurances as well. Moreover in many cases the social insurance systems mean the decisive factor. This is true even if we consider that there is a direct insurance service in connection with the social insurance taxes, which service, in case of pension and health insurance, is proportional with the paid taxes. A good example for this is the effect of the last decade’s single rate tax reforms on economy and tax morale, where differences were explained by the different transformation of social insurance systems and taxes (Keen et al. 2006).

In the opinion of OECD experts the citizens responses reveal socioeconomic and institutional factors that may influence tax morale. (OECD, 2013)

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

The World Values Survey gives data to help build a better picture of tax morale. The OECD used data from WVS, which covered around 90 countries¹³.

Some very interesting observations can be found in this paper, like: “Individuals are more likely to perceive tax obligations more favourably when their government is seen to be acting in a trustworthy manner”. (OECD, 2013. p. 7.)

When state strengthens and clarifies the links between revenue and expenditure it can help to improve tax more of society. Increase the transparency of tax policy making, increase the number of tax administration procedures: these measures would reduce opportunities for corruption and the willingness the cheat with tax revenues.

Hungarian deliberations and initiations

According to Kornai’s (1990) thoughts Hungarian tax policy should be based on impersonal tax elements. Besides sales tax (which has even reached record level within the EU) we should improve wealth tax. This aspect is in line with OECD’s suggestions. The income from wealth taxes in OECD countries make up for the 2% of GDP. For Hungary it was only 1% in 2008. In this sense the attempt to introduce property tax in 2009¹⁴ wasn’t groundless, although it was annulled by the constitutional court in 2010. In its regulation the court expressed that the tax in itself wasn’t against the constitution, only the method of calculating the rateable value was inappropriate¹⁵.

¹³ Hungary was not involved in the survey, for Eastern Europe Bulgaria, Moldova, Poland, Romania, Russia, Serbia, Slovenia, Ukraine was involved.

¹⁴ The Hungarian Parliament accepted the law on the taxation of high value assets on the 29th of June, 2009.

*Suggestions of experts of National Bank to improve taxation and tax morale in Hungary*¹⁶

The tax burden on employees and self-employed has to be equalled. It decreases the attempt to show incomes from work as incomes of entrepreneur activity. Moreover allows decreasing the burden of work and increases horizontal equality, which can raise the justice of taxation and increase tax morale.

Improving trust toward the system of pension. Superannuation tax, in theory, opposite to taxes means that we will have as much pension in the future as much money we paid, so paying this can be considered as an inevitable saving which secures subsistence in old age. Avoiding paying superannuation tax can have more causes. On the one hand it can be motivated by the discredit in the system of pension. People may think that they can take care about their own savings in a better way and these liquid savings act also as a security till then.

Increasing local incomes from taxes. In theory those payments which are in relation with local services can be more acceptable, because the connection between payments and services can be more sensible. According to Tiebout model, individuals are like customers, when they decide about at which self-government's area they should move on the basis of "programs" (Tiebout, 1956). In this sense the local tax payer votes with its feet. It makes possible to produce local utilities efficiently, because tax payers decide about secured public utilities on the basis of local taxes, like customers decide what to buy, considering market price. Until taxes are in harmony with marginal cost - which means the extension of local services for new settlers - the result will be optimal in Pareto sense like in the case of private sector. As an example local entrepreneurship tax offered to companies by the self-government can inspire developments and local services.

Tax amnesty should be avoided. According to international experience (e.g. Greece) tax amnesty can decrease tax morale, and if repeated amnesty is expected then willingness of paying taxes may also fall.

Developing the communication of tax authority to improve tax morale. In 1996 IOTA (Intra-European Organisation of Tax Administrations) has been established to support the cooperation of different tax authorities in different countries. 44 national tax offices joined the organization. The

¹⁶ http://www.mnb.hu/Root/Dokumentumtar/MNB/Kiadvanyok/mnbhu_mnbtanulmányok/MT_65.pdf

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

office of IOTA is in Hungary, Budapest¹⁷. By the help of this organization the practice of national communication techniques is shared, as well as the fair administration and the experience of teaching students about taxation.

According to the results of a research made by the British tax authority, every authority after understanding the mechanism of tax payers' behaviour should have the possibility to change parameters of the tax-system to inspire tax payers to pay their tax more properly. As a result of this research the tax gap was decreased by the help of information about tax payers. The methods are the following:

- decreasing administrative limits and simplifying the processes at those tax payers who fulfilled their payment duties
- making preventive advices and developing education at those tax payers who fulfilled their payment duties only partly
- carrying out proportional penalties at those tax payers who violated their payment duties¹⁸.

Methodology of the research

Due to these negative socio-economic conditions I decided to observe the willingness of tax paying of individuals, and their knowledge about the share of self-governments from the state tax income as well as their opinion about those immoral behaviour which are against the taxation rules. In order to test I used a survey questionnaire which can be found in the annex of the paper.

The questionnaire was filled by 95 persons, mostly part-time students taking part in adult education at the Budapest Business School and some employees of BBS.

The dependent variable was the individual level of tax morale and the explanatory variables were demographic variables, personality characteristics, commitment to local self-governments, willingness of taking different levels of risk, etc. The used statistical methods for testing the relations between the variables were the following: multivariate correlation and regression, analysis of variance, t-tests for testing correlation coefficients. The general level of significance is 5%, unless it is stated otherwise.

Empirical results

Out of the 95 participants 75 answered that there exist shared state taxes. According to them the local self-governments receive on average 29% of the total vehicle tax while this ratio is much lower, only 10.82% on average in case of PIT. (Note, that the right answer was 40% in case of vehicle tax and 0% in case of PIT.) However it is noteworthy that the standard deviation of the answers is rather large either in the case of vehicle tax or in the case of PIT: 31.75 and 17.55 percentage point respectively (which means that the coefficient of variation is above 100% in both cases, meaning that the answers are quite heterogeneous). Generally we can say that respondents are not really aware of the right share of state taxes but they mostly consider lower shares of the total tax revenue of the state, however there are a few exemptions as well (e.g. there were also responders who believe that 100% of the vehicle tax and PIT is received by local self-governments).

Not only the measure of shared state taxes are not clear for most of the responders but even the 20 cases out of the 95 can be considered as too low who answered that there are no shared state taxes in Hungary at all. My assumption was that adult students of economics (not freshmen) who are 30 years old on average know the fact that either the vehicle tax or the PIT are shared state taxes which form the income of tax systems both on state and local level. This significant ignorance may cause the high level of variation in the answers concerning the shares of local governments from the mentioned two state taxes.

It is important to emphasise that exactly half of the responders would accept even higher tax rate if they were sure that the surplus above the official tax rate is the exclusive revenue of the local self-government. As it is visible in Table 1, males have significantly higher willingness to accept higher tax burden for this reason. Compared to the current 16% PIT rate, males would accept even more than two percentage point higher tax rate in order to help the functions of the local self-governments. In case of females this extra tax burden is almost one percentage point lower on average which difference between the two gender is significant ($F=5.31$; $p=0.023$).

Female	1.16	1.55

Source: own calculation.

It is generally accepted that payments in connection with local services are typically more accepted since the relation between the payment and the service is more appreciable (Tiebout, 1956). According to this model the individuals appear as consumers who decide to which local self-government they move based on the possibilities they have to offer. In the view of Tiebout it makes possible to efficiently produce local public goods since the customers choose from the public goods provided by the local communities based on the level of local taxes similarly to the choice of the customers in the market based on the prices of products¹⁹.

As a result, inhabitants and enterprises with the same preferences will be concentrated in the same district. The theory of Tiebout resulted in several models of efficient inter-governmental race for mobile resources of economy.

Table 2 contains the correlation matrix of the observed variables. Those correlation coefficients are marked by bold which are significant at the 5% level. In the following the most important ones are discussed which are interesting for the research topic.

It seems that men support the finance issues of local self-governments more than females, since they are not only willing to pay higher tax burden in order to increase local revenues but they assume that self-governments receive higher shares from vehicle tax and PIT. However this is only an assumption at their side, which is possibly a higher share than the actual real rate, it is noteworthy. I do not consider it as a systematic failure of overestimation by males. In connection with the males' willingness of paying higher tax burden, I think it shows rather the pursuit that males support more the delegation of the use of public resources at the local level.

¹⁹ As long as the payable taxes are in line with the marginal cost of expanding the local services to a newcomer, the result can be considered as Pareto optimal like in the case of private sector. For example the local business tax may support those developments and local services which are offered to entrepreneurs by the self-governments.

Source: own calculation.

Responders were asked to imagine the situation that the general PIT burden is 30% and they have realised 1 million HUF income for an extra work which is similar to their general occupation but not part of their job. They have the possibility to buy a fictive invoice of half million HUF which can be considered as cost and this way it reduces the income to its half. The question was, how much percent of the nominal value of the invoice are they willing to pay in case of different risk levels of being caught. The answer at 0% of risk is considered as the individual level of tax morale. The possible maximum for this question is 30% since it would be totally against the rational decision making if anyone paid more than 30% of the nominal value of the invoice in case of 30% tax burden. If someone is willing to pay the total tax burden (30%) to a third party instead of the state then his/her tax morale is considered as zero (0%). If someone refuses to pay anything for a fictive invoice even in a riskless option then his/her tax morale is considered as full (100%). So the answers for the riskless option (between 0 and 30%) were transformed to a scale between 100 and 0%.

Maybe it is surprising that 29.5% of the responders would pay even the total tax burden for a fictive invoice instead of paying it to the state budg-

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

et... Even if there is no risk of being caught it must be clear for all that this behaviour is immoral and causes damages for the society.

As it was expected there is direct relationship between the level of Machiavellian personality and the maximum amount paid for a fictive invoice in a riskless option ($r=0.346$). It can be explained by two reasons: on the one hand it is not a dilemma to reach individual gain at the expense of the society for people with strongly Machiavellian personality, while on the other hand these people consider the state leaders typically as opportunistic and self-serving persons which may justify their behaviour of decreasing the tax revenues.

There is a less than intermediate strength, indirect relationship between the age of responders and the maximum amount paid for a fictive invoice in a riskless option ($r=-0.246$). Anyway, it has to be emphasised that it does not mean at all an increasing tax morale as time passes. This research compared the answers of people as cross-sectional data and it shows that the tax morale of older people is significantly higher at the date of observation. Obviously it does not mean that the tax morale of the younger people will be better as they are getting older. The appalling thing is that after several years, as the older people of now will retire and get out of the sphere of active tax payers, their place will be taken by this younger generation with its lower tax morale. All in all, the current situation does not support the increase of tax morale in the next years. In my opinion some important steps are necessary to reverse this negative tendency concerning the tax morale of the younger generation. Without a successful intervention of the state the tax morale will not get better (e.g. "I was not caught so far, why should I pay in the future?") and what is worse, this rather negative tax morale will be the example for the next generations.

The maximum amounts paid for a fictive invoice in case of different levels of risk are not independent of each other. Obviously only those people will pay for a fictive invoice in a risky option who would do this also in a riskless option, however vice-versa it is not necessarily true. It can be seen in Table 2 that strong relationships are only between the low risk options and between the high risk options. There is a more than intermediate strength direct relationship between the maximum amounts in case of the riskless and low risk options ($r=0.621$), while there is a strong direct relationship between the maximum amounts in case of the high risk options ($r=0.801$). Naturally the risk of being caught influences negatively the maximum amount paid for a fictive invoice which can be observed in Table 3.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

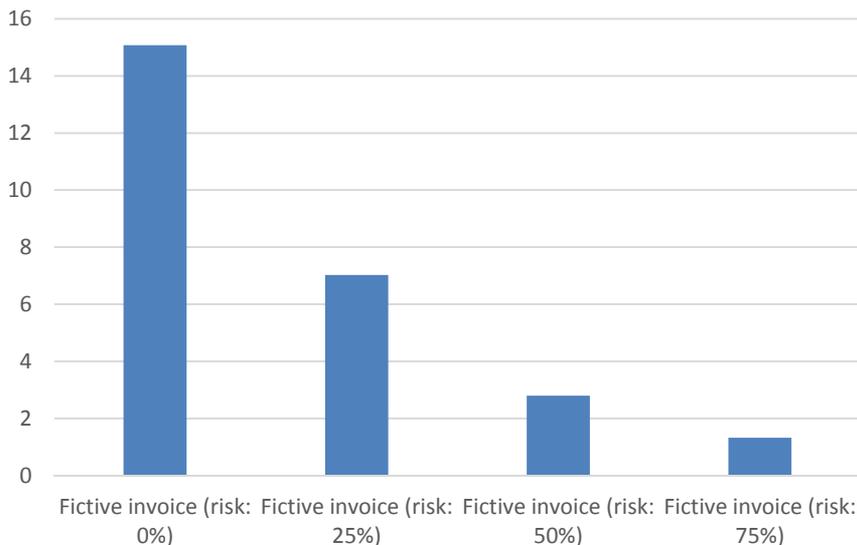

In case of no risk the responders are willing to pay on average even the half of the tax burden for a fictive invoice. If the risk is 25% then this amount decreases to its half. As the risk increases the amount decreases exponentially. This indirect relationship is strong and significant even below the 1% level ($F=48.56$; $p=0.0000$).

Table 3. Relation between the risk of caught and tax morale (percentage point)

<i>Risk level</i>	<i>Mean</i>	<i>St. dev.</i>
Fictive invoice (risk: 0%)	15.07	12.47
Fictive invoice (risk: 25%)	7.03	9.44
Fictive invoice (risk: 50%)	2.80	5.71
Fictive invoice (risk: 75%)	1.33	4.57

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

Even though the sample is not representative, it is visible that in case of no or minimal supervision the fictive invoice is a real option to reduce the tax base for those who have some extra income. However the willingness for this kind of manipulation intensively decreases if the risk level reaches at least 50%. Considering that there are no exact data for the tax payers about the real risks, these are more-or-less some kind of subjective probabilities, there is a good possibility to reduce tax evasion by strengthening the general belief about the efficiency of supervision and the higher and higher risk of being caught.

The Hungarian National Tax and Customs Administration (NTCA) has introduced a more efficient and more powerful supervision system after its organisational transformation in 2011. In 2012 there were 2029 supervision processes concerning private asset growth which is almost double than in 2011. Out of the 2029 supervisions 1578 (78%) finished with a sanction, resulting altogether 20.6 billion HUF tax difference that is 89% higher than in the previous year. I do not believe that tax morale can be strengthened only by increasing the number of supervision processes or by increasing the level of tax fines, however it may have enough restrictive power for tax payers with “vacillating” tax morale in case of significant risk of being caught.

The regression coefficients of those explanatory variables which are in the closest relation with the tax morale can be seen in Table 4.

Table 4. Explanatory variables of tax morale

<i>Coefficients</i>	b_i	$s(b_i)$	<i>t-value</i>	<i>p-value</i>
Constant	56.974	20.443	2.787	0.006
Mach score	-0.775	0.274	-2.830	0.006
Gender	-9.273	8.175	-1.134	0.260
Age	0.804	0.494	1.627	0.107

Source: own calculation.

The Mach score of the responder influences indirectly and most significantly the individual tax morale. Both variables are measured on a scale between 0 and 100. In case of 1 point higher Mach score (more Machiavelian personality) the tax morale is on average 0.78 points lower according to the regression, which effect is significant below the 1% level ($p=0.006$). It is easy to realise how strong and deteriorative is this effect: compared to a generally well-meaning person (let's suppose a low Mach score of 20) a

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

person with more or less Machiavellian personality (a Mach score of 70 is not rare) has on average cca. 40 points lower tax morale.

Generally speaking the tax morale of males is a little lower than females, however the effect of gender is not significant ($p=0.26$).

In case of the effect of age we can repeat that the tax morale of older generations is currently significantly better than the younger generations (a one year older responder's tax morale is on average 0.8 points higher), which effect is significant at the 10% level.

The multiple coefficient of correlation for the total regression function is $R=0.4$ ($F=5.63$; $p=0.0014$). So we can conclude that the exploration of some further influencing factors is necessary, however the Mach score is a significant determinant of tax morale and possibly the generation effect is also important.

Conclusions

One goal of my study was to create a structure to help defining tax morale which is a complex phenomenon, examined by the tools of law, economy, sociology and psychology. In my paper I analysed the Hungarian tax morale in connection with personal aspects, the taxation of the socialism and the period after the regime change.

We have seen by the help of some historical examples and some actual macroeconomic data that the level of tax morale is quite low in Eastern-Central European countries like Hungary. Based on a questionnaire survey answered by 95 Hungarian people this fact is supported and we observed the main reasons and motivations of this low tax morale.

The questionnaire was filled by 95 persons, mostly part-time students taking part in adult education at the Budapest Business School and some employees of BBS.

Out of the 95 participants 75 answered that there exist shared state taxes. Generally we can say that respondents are not really aware of the right share of state taxes but they mostly consider lower shares of the total tax revenue of the state, however there are a few exemptions as well.

Not only the measure of shared state taxes are not clear for most of the responders but even the 20 cases out of the 95 can be considered as too lot who answered that there are no shared state taxes in Hungary at all. My assumption was that adult students of economics who are 30 years old on average know the fact that either the vehicle tax or the PIT are shared state taxes which form the income of tax systems both on state and local level.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

Maybe a less complicated, more transparent and easier to understand tax rules would be able to strengthen the willingness to pay taxes properly.

It seems that men support the finance issues of local self-governments more than females, since they are not only willing to pay higher tax burden in order to increase local revenues but they assume that self-governments receive higher shares from vehicle tax and PIT. In connection with the males' willingness of paying higher tax burden, I think it shows rather the pursuit that males support more the delegation of the use of public resources at the local level.

There is a less than intermediate strength, indirect relationship between the age of responders and the maximum amount paid for a fictive invoice in a riskless option. Anyway, it has to be emphasised that it does not mean at all an increasing tax morale as time passes. This research compared the answers of people as cross-sectional data and it shows that the tax morale of older people is significantly higher at the date of observation. All in all, the current situation does not support the increase of tax morale in the next years. In my opinion some important steps are necessary to reverse this negative tendency concerning the tax morale of the younger generation.

Concerning the personal characteristics, Machiavellian personality shows indirect relation with willingness of taxpaying. The Mach score of the responder influences indirectly and most significantly the individual tax morale. Both variables are measured on a scale between 0 and 100. In case of 1 point higher Mach score (more Machiavellian personality) the tax morale is on average 0.78 points lower according to the regression.

Naturally this survey was not representative, however it is still able to show which points of the system are to be changed urgently. A less complex but more proportional tax system which is easier to understand for most people, with a more transparent and effective redistribution of collected taxes, besides an efficient tax control could significantly increase the general level of tax morale.

**Valuation Effect as a Determinant of the
International Investment Position in Central and
Eastern European Economies**

JEL Classification: *F36; F41; F62; G15*

Keywords: *international finance; valuation effect; international investment position; Central and Eastern European economies*

Abstract: The aim of this paper is to evaluate the significance of the valuation effect in determining the dynamics of the net international investment position of CEE economies. For this purpose an analysis of BoP and IIP time series for the four largest CEE economies (Poland, the Czech Republic, Hungary and Romania) for the years 2005-2013 was carried out. The exercise revealed that the valuation effect (VE) is, in the short run, the key determinant of net IIP changes (for most observed years). Nevertheless, in the long-run its influence decreases as valuation gains and losses tend to cancel each other out. As the VE is relatively volatile, it is important to analyse its dynamics over the mid and long-term when evaluating the IIP. The significance of the VE for determining net IIP dynamics turned out to be non-investment-type specific because valuations of both the short-term and long-term investments contributed in a large part to the change in the net IIP. Similarities in the dynamics of the VE in CEE countries prove that the VE depends to a large extent on the general price fluctuations in financial markets that nowadays exhibit strong correlations across countries.

Introduction

Economic transactions between residents and nonresidents influence the level of foreign assets and liabilities compounding the international investment position (IIP) of a national economy. The IIP, being an international balance sheet of the economy, is one of the closely analysed variables when evaluating an economy's external position. The net IIP, measured as a difference between the levels of foreign assets and liabilities, indicates whether the economy is a net debtor or creditor to the rest of the world; which in turn defines risks to which the economy is exposed in an international context. However, international transactions are not the only determinant of net IIP fluctuations. The other factor underlying the changes in the net IIP are valuation adjustments to existing stocks of assets and liabilities.

Empirical research indicates a significant role for the valuation adjustment in determining the IIP in developed countries and in some developing countries. Lane and Milesi-Ferretti (2001) estimate foreign assets and liabilities for 67 countries (excluding Central and Eastern European transition economies) for the period 1970–1998 based on balance of payments data and explore the sensitivity of the estimates to the valuation adjustment. They indicate that the valuation effects are quantitatively important for a number of countries in the sample. Higgins et al. (2007) prove a large role for the valuation effect in determining the net IIP of the United States during the period 2001–2005. Gourinchas (2008) indicates that short-term fluctuations in a country's external asset position appear to be increasingly driven by the valuation component. He measures the cumulative valuation effect (since 1950) in a sample of industrialised countries and concludes that it is significant and has been growing in recent years: reaching 50% of GDP in the UK in 2000, 20% of GDP in the US and Canada in 2004 and slightly less in Australia. Macias and Nash (2007) point out that the valuation adjustment explains 55% of the change in the Spanish net IIP between 1993 and 2004. Devereux and Sutherland (2010) measure the importance of the valuation term in a sample of 23 OECD countries during the period 1980–2006. As the ratio for the variance of the valuation term to the variance of the change in net IIP is well above 50% for most countries, they conclude that the evolution of the net IIP is dominated by valuation gains and losses resulting from changes in asset prices and exchange rates. Gourinchas and Rey (2013) measure valuation effects for 10 countries in the 1970s, 1980s, 1990s and 2000s. Their research indicates that the importance of the valuation effect has been increasing over time and the aver-

18-19 June 2015, Economics and Finance**

age magnitude of the current account transactions tend to be dominated by the average magnitude of valuation effects for determining the IIP adjustment in most of the countries analysed (the US, the UK, Ireland, Brazil, Russia, India, Switzerland).

During the decade after the accession to the European Union, the financial integration of Central and Eastern European economies (CEE) with the rest of the world advanced, which significantly influenced their IIP. Throughout this period changes in the valuation of foreign assets and liabilities were important in terms of determining the net IIP of CEE countries amid price fluctuations in international financial markets. The aim of this paper is to evaluate the significance of the valuation effect for determining the dynamics of the net IIP in CEE economies. Within the empirical research conducted the following hypotheses were verified:

- the valuation adjustment of foreign assets and liabilities as the key determinant of the net IIP dynamics in CEE economies,
- the significance of the valuation effect in determining the dynamics of net IIP in CEE economies as investment-type specific because investments of a short-term nature tend to be associated with a larger valuation effect.

In order to verify the hypotheses a statistical decomposition of a time series for balance of payments and IIP data was conducted. The time span of the analysis covers the years 2005-2013. The sample consists of the four largest CEE economies based on GDP¹ ranking; i.e. Poland, the Czech Republic, Hungary and Romania².

The structure of the paper is as follows. The first section depicts methodological aspects related to measuring fluctuations in the net IIP. In the next section fluctuations in the external investment position of CEE economies are presented and decomposed into contributing factors. The third section describes the significance of the valuation adjustment for major types of international investments. The conclusions from the analysis are presented in the final section.

¹ GDP at market prices in 2013 amounted to 389.7 billion EUR in Poland; 149.5 billion EUR in the Czech Republic; 142.2 billion EUR in Hungary, and 98.0 billion EUR in Romania (Eurostat data).

² Research project supported with funds from the National Science Centre.

Methodology of the research

A change in the net IIP position is the outcome of changes in stocks of foreign assets and foreign liabilities, which are in turn determined by foreign transaction flows and valuation adjustments. There are two approaches to measuring the determinants of net IIP changes. The first approach is to look at financial flows between residents and nonresidents, which include official reserve asset transactions. The second approach emphasizes flows resulting from current transactions as the reason for net IIP changes. Through balance of payments accounting identity, financial flows (including reserve asset transactions) are a counterpart to current transactions (including current and capital account transactions as well as errors and omissions). As a consequence a deficit / surplus stemming from current transactions in the balance of payments is associated with a surplus / deficit in financial flows, which in turn leads to a decrease / an increase in the net IIP of an economy³.

$$\Delta N I I P = C A B + K A B + E O + V E \quad (1)$$

$$C A B + K A B + E O = -(F A B + R E S) \quad (2)$$

where:

- $\Delta N I I P$ – change in the net international investment position,
- $C A B$ – current account balance,
- $K A B$ – capital account balance,
- $E O$ – errors and omissions,
- $F A B$ – financial account balance,
- $R E S$ – reserve asset transactions (balance on official settlement transactions).

³ Changes in the net IIP can also be analysed on a relative basis (by looking at changes in the ratio of net IIP to GDP). The concept of the dynamics of external positions measured on a relative basis is presented in Lane and Milesi-Ferretti (2007a, pp. 73-74; 2007b, pp. 531-533,565-567).

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

The valuation effect (adjustment) is defined in the paper as a change in the net IIP which does not stem from foreign transaction flows. As a consequence the valuation adjustment is derived as the difference between the actual change in the net IIP and the balance on financial flows for a given period:

$$VE = \Delta NIIP + (FAB + RES) \quad (3)$$

where:

VE – valuation effect, with the rest of the notation as presented above.

**Fluctuations in the net external investment position of CEE economies
– an analysis of the underlying factors**

The abovementioned concept is exemplified below using the IIP data of CEE economies in the years 2005-2013. All four analysed CEE economies were net international debtors throughout the period as foreign liabilities surpassed foreign assets. What is more, in the analysed period the economies experienced a drop in the net IIP as the increase in foreign liabilities outpaced the growth in foreign assets⁴. In absolute terms, the mismatch between the growth in assets and liabilities was most noticeable in Poland (243.8 billion USD) and least significant in Hungary (17.5 billion USD)⁵. Among current transactions, the major contributor to the decrease in the net IIP in all CEE countries was the current account deficit (ranging from 29.2 billion USD in Hungary to 174.2 billion USD in Poland). At the same time, the capital account closed with a positive balance in all countries (mainly as a result of capital transfers from the European Union), positively affecting the net IIP level. Statistical discrepancies closed with a negative balance in all countries.

The combined current and capital account deficit (including errors and omissions) was reflected through an inflow of capital, leading to a positive

⁴ For a detailed analysis of the IIP dynamics in CEE economies during the period 1998-2007 see Sobanski (2010, pp.150-170).

⁵ In relative terms, the decrease in the net IIP for the analysed period amounted to 6.6% of GDP in Poland, and 1.5% of GDP in Hungary.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

balance in the financial account (adjusted for official settlement transactions). In the whole period analysed the financial flow ranged from 24.8 billion USD in Hungary to 170.3 billion USD in Poland. Whereas in the early years of the period the financial flow was a negative contributor to the net IIP adjustment in all CEE economies, later, the situation started to change. From 2009 the contribution of the financial flow began to diminish or even reverse to the positive side in some countries as a result of prevailing current account reversals (in Hungary, even turning trade deficits into trade surpluses).

The other factor influencing the net IIP was the valuation effect. The direction of its influence was different across the economies analysed. In Hungary, valuation adjustments led to an improvement in the net IIP for the years 2005-2013 (by 7.3 billion USD); whereas in Poland, the Czech Republic and Romania, to its deterioration (by 73.6, 20.8 and 7.9 billion USD respectively).

Table 18. Factors underlying changes in the net IIP of CEE economies for the years 2005-2013

Other remarks: A negative change in the net IIP results from the relative increase of foreign liabilities as compared to assets (i.e. a larger increase in liabilities than assets or a smaller decrease in liabilities than assets). Current account, capital account, errors and omissions, financial account, and reserve asset transactions represent respective balances from the balance of payments. The valuation effect represents the change in the net IIP resulting from valuation adjustments to stocks of foreign assets and liabilities.

Source: own compilation on the basis of International Monetary Fund data (International Financial Statistics, Balance of Payments Statistics) [accessed on: 03-12.05.2014; 03-07.11.2014].

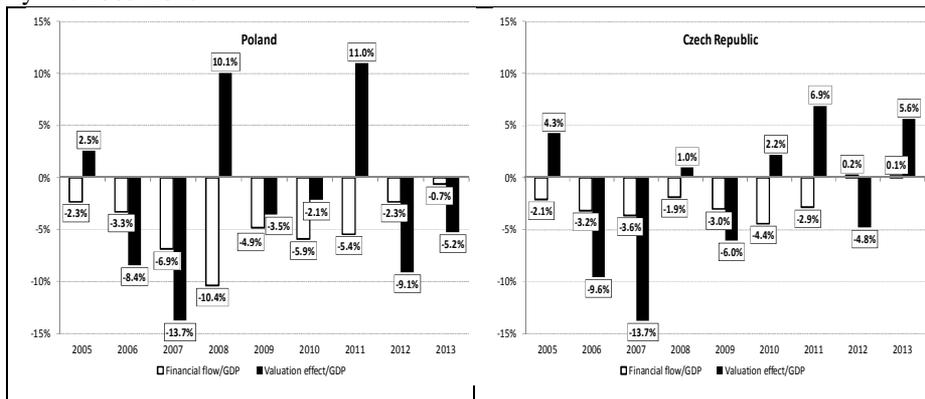

The significance of the valuation effect is even more apparent when one analyses the annual data. The VE was the major determinant of the IIP changes in most observed years in Poland, the Czech Republic and Hungary; and in one third of cases in Romania. The average annual contribution of the VE to net IIP fluctuations far exceeded 50% in Poland, the Czech Republic and Hungary (amounting to 60%, 69% and 56% respectively) and

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

was close to 40% in Romania⁶. The significance of the valuation adjustment is also apparent when compared to the size of the respective economy. On average it amounted 3.5% of GDP each year in Romania and more than 6% of GDP in the remaining CEE countries⁷.

The contribution of the VE was relatively volatile as it changed the sign from a positive to a negative one (and vice versa) several times. In the years preceding the outbreak of the world financial crisis, valuation adjustments increased the net foreign liabilities of CEE economies, which was a reflection of the rising prices of financial instruments across the globe. For instance, in 2007 the net IIP deteriorated by almost 14% of GDP in Poland and the Czech Republic simply as a result of valuation amendments to existing stocks of foreign assets and liabilities. In the years 2010-2011 the VE positively affected the net IIP; leading to a drop in the net foreign liabilities of CEE economies (this was especially apparent in Hungary, where the positive contribution exceeded 11% of GDP in each year).

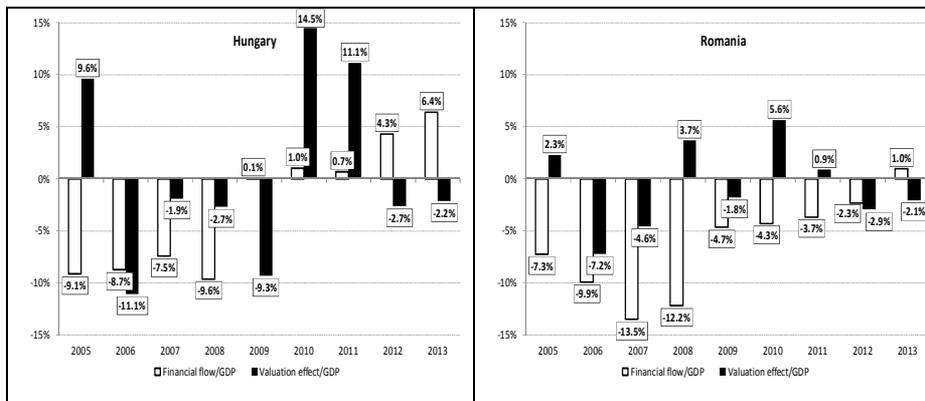

Figure 11. Decomposition of changes in the net IIP of CEE economies for the years 2005-2013

⁶ The contribution is estimated as the relation of the absolute value (modulus) of the VE to the sum of the absolute values of the VE and the financial flow.

⁷ The average is calculated based on the absolute values of the VE.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

Other remarks: The financial flow represents the contribution of the financial account balance and official transactions in reserve assets to changes in the net IIP. The VE represents the change in the net IIP resulting from valuation adjustments to stocks of assets and liabilities. Both variables are presented on a relative basis, i.e. as a share of GDP.

Source: own compilation on the basis of IMF data (IFS, BoPS), OECD data, and Euro-money Institutional Investor Company data (CEIC) [accessed on: 03-12.05.2014; 03-07.11.2014].

The valuation adjustment for different types of international capital flows in CEE economies

The VE for the net IIP can be decomposed into the valuation effect on the assets side as well as the liabilities side of the investment position. As both assets and liabilities are not uniform categories it is advisable to further analyse different categories of investments, compounding assets and liabilities separately. One can differentiate between foreign direct investments, portfolio investments, other investments and derivatives. Additionally, reserve assets play an important role on the assets side of the IIP.

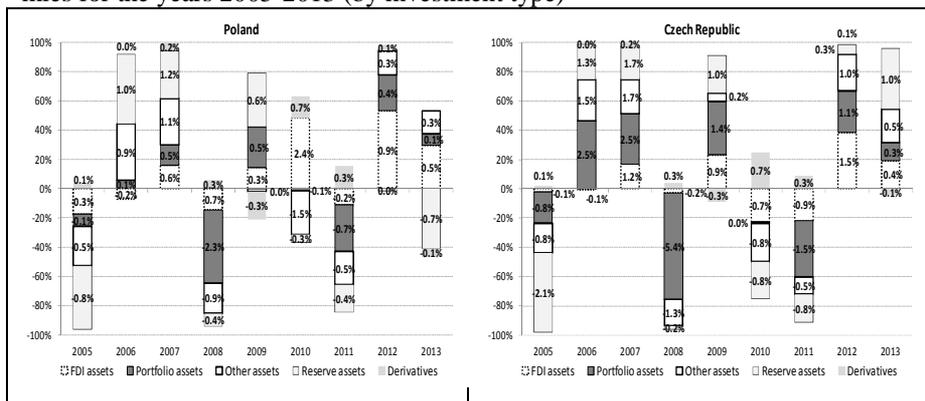

In general, there is no clear indication in CEE countries that a specific type of international investment was dominant in creating exposure to the valuation effect for the net IIP. Exposure by investment type was differentiated across countries and time as well as between assets and liabilities.

In the largest CEE economy, i.e. Poland, the average annual valuation effect (2005-2013) for all types of assets did not surpass 0.6% of GDP. In the Czech Republic portfolio assets were among most affected by valuation adjustments (1.5% GDP on average). In Hungary valuations of FDI, derivative assets and other investments fluctuated by more than 2.5% of GDP on average. However, it should be taken into account that the huge valuation adjustments to FDI stocks occurring since 2006 are in large measure due to

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

a change in the methodology of presenting transactions of SPEs⁸ in this country. In Romania, valuation adjustments were much less significant than in other countries, as foreign assets were of much lower importance in the national economy (one exception being official reserve assets).

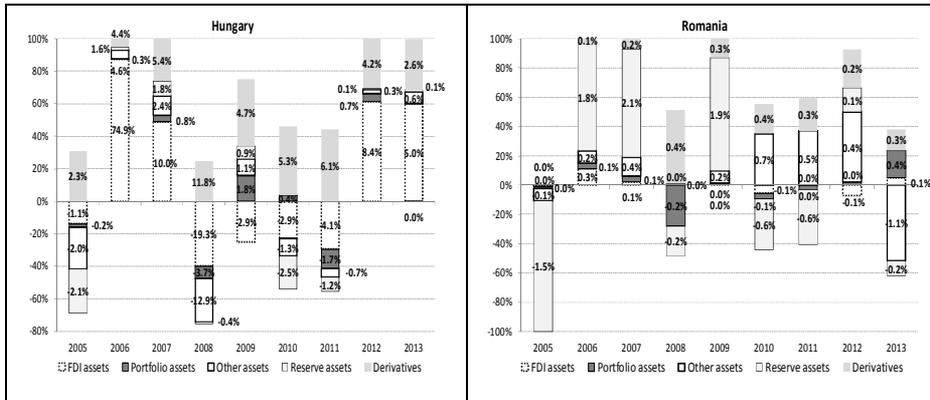

Figure 12. Decomposition of the valuation effect on foreign assets of CEE economies for the years 2005-2013 (by investment type)

⁸ The change in methodology followed an amendment to corporate tax law in 2002 that ended offshore status for tax purposes. From 2006, the MNB (Hungarian Central Bank) reported the balance of payments and international investment position data to international institutions in accordance with international statistical standards to allow for international and bilateral comparisons of statistics. As a result, data on flows and stocks of SPEs (enterprises set up in Hungary solely for tax optimisation purposes) are recorded on a gross basis. Thus, comparability of data for 2006-2013 with data for previous periods is limited. See [MNB, 2014a; ECB, 2007, pp. 359-360; UN Economic Commission for Europe, Eurostat and OECD, 2011, pp. 60-63].

SPEs activities are of a relatively large size in comparison to Hungarian GDP. According to the MNB the total gross loan portfolio of SPEs hovers in the range of 20-40 per cent of GDP [MNB, 2014b, p. 31]. However, one should take into account that the operations of SPEs playing a passive role in the intermediation of financial resources within international capital groups can lead to misinterpretation when analysing the real economic impact on the domestic economy. SPEs' operations are mainly limited to gathering funds from foreign sources and channelling them abroad. As a consequence, gross credit and debit flows resulting from SPE operations are of a similar magnitude and net flows over an extended period are close to zero [MNB, 2014a, 2014b].

Other remarks: The height of the bar for each year is equal to 100% and is measured on the y-axis. The height of a section of the bar represents the share of a given type of asset in the total VE in a given year. Numbers provided within a bar or alongside represent valuation effects for the respective assets presented as a share of GDP in a given year.
Source: as in Figure 1.

CEE economies are net international debtors and their foreign liabilities exceed by far their foreign assets. For this reason the influence of the VE in respect of liabilities on the net IIP is usually much more significant than that of the valuation adjustment for assets. This was clearly observable in the period analysed.

In all CEE economies the changes in FDI valuations were at the forefront of liability fluctuations (with an annual average influence of 4.6% of GDP in Poland, 9.6% in the Czech Republic, 15.3% in Hungary⁹ and 2.3% in Romania)¹⁰. For portfolio liabilities the VE was also differentiated across countries: from 0.3% GDP in Romania to 5.0% in Hungary. The average annual adjustments to the valuation of other liabilities amounted to app.

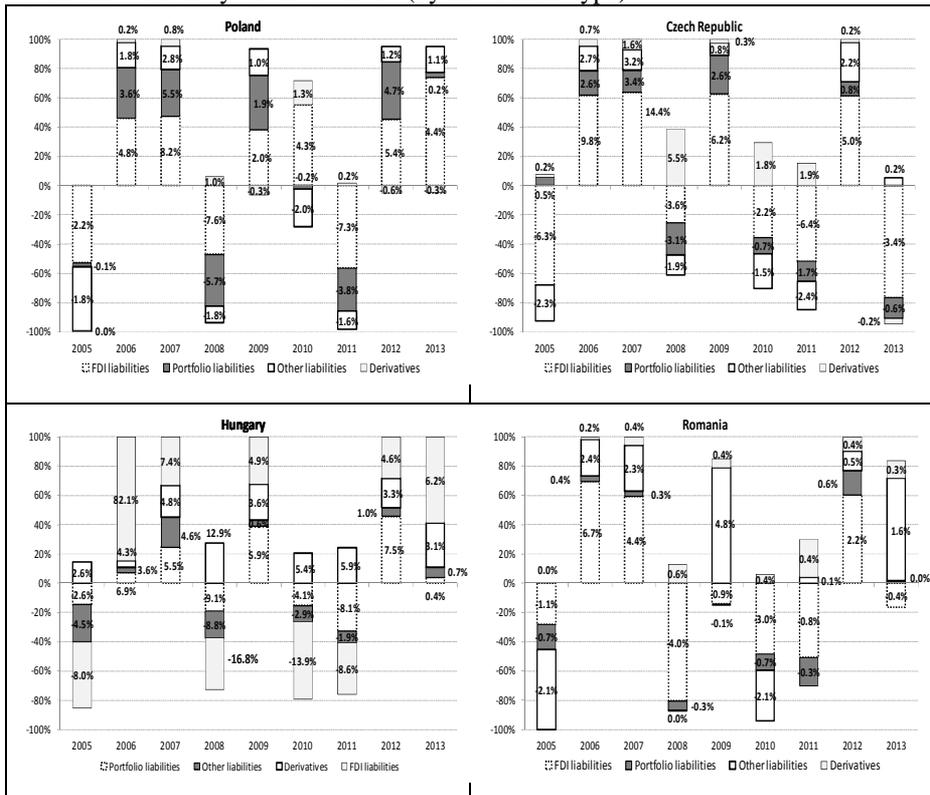

⁹ See comment in the previous footnote.

¹⁰ The size of the valuation effect may depend to a large extent on the method of valuation applied to a given type of foreign investment. Damgaard and Elkjaer (2014) and Kumah et al. (2009) indicate that the valuation method and the estimation technique can significantly affect a country's international investment position. Damgaard and Elkjaer (2014) exemplify this using the IIP data on FDIs for Denmark. Danish unlisted FDI equity liabilities vary from 22% to 156% of GDP depending on the estimation technique being applied under the price to earnings valuation method. To make cross-national comparisons easier the IMF implemented the Balance of Payments and International Investment Position Manual, sixth edition (IMF, 2009). However, as Damgaard and Elkjaer (2014) point out, the manual recommends seven methods for valuing unlisted FDI which makes international comparisons difficult.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

1.5% of GDP in Poland, the Czech Republic and Romania, and around twice as much in Hungary. Liabilities on derivatives were of less importance except for Hungary, where the average valuation adjustment amounted to 4.6% of GDP (close to the VE on assets) – which is again a reflection of the important role of SPEs in Hungary.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

It worth mentioning that the sign relating to the VE (both on assets and liabilities) was frequently changing from year to year. The pattern of the sign changes was similar across countries, which proves that the VE depends to a large extent on the general price fluctuations in financial markets which are positively correlated across countries (and not just on the country specific structure of the IIP).

One should bear in mind that the relative significance of valuation adjustments for a given type of investment (expressed as a percentage of GDP) is an outcome of the valuation variability and the size of the investment stock. In order to isolate the influence of the size of investment stock and look specifically at price fluctuations, one can measure valuation adjustments in relation to prevailing stocks of these investments. Using this approach, it is quite apparent that in all CEE countries derivatives (not surprisingly) experienced the largest price fluctuations, followed by FDIs and portfolio investments. For these two latter types of investments, equity instruments were the major reason for valuation adjustments.

Conclusions

During the last decade CEE economies experienced a change in foreign assets and liabilities that contributed to a significant decrease in the net IIP. The path of these changes was not smooth because the underlying factors were affecting the net IIP in opposite directions and in a variable manner. One of these factors was the valuation adjustment to existing stocks of assets and liabilities.

The valuation effect was the key determinant of the net IIP changes in the short run (i.e. for most observed years). Nevertheless, in the long-run (i.e. from the perspective of the whole analysed period) its influence decreases as valuation gains and losses tend to cancel each other out, whereas surpluses of financial flows tend to persist. Because the VE is relatively volatile (the sign relating to its influence frequently changes from positive to negative), when evaluating the IIP it is important to analyse its dynamics over the mid and long-term.

The significance of the valuation effect for determining the net IIP turned out not to be investment-type specific because valuations of both the short-term and long-term investments contributed in a large part to the change in the net IIP. At the same time, the importance of the VE by investment type was differentiated across countries and time as well as between assets and liabilities. Although no specific type of international in-

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

vestment was dominant in creating exposure to the VE consistently, the prices of derivatives, followed by FDIs and portfolio investments, were the most volatile in percentage terms. For the latter two types of investments, the equity component was the major contributor to price fluctuations.

There are similarities in the dynamics of the VE in CEE countries, which proves that the VE depends to a large extent on the general price fluctuations in financial markets that nowadays exhibit strong positive correlations across countries (not just on the country specific structure of the IIP). Undoubtedly, the significance of the valuation effect in the analysed period was positively affected by sudden fluctuations in the prices of financial instruments amid the world financial crisis starting in 2008.

Tax Incentives for Innovation

JEL Classification: *O31; O38; H21*

Keywords: *innovation; R&D; tax incentives; tax credit; tax competition*

Abstract: Tax incentives for innovation, including in particular the incentives for R&D investments, are universally used policy tools. Their availability and generosity have significantly increased over the past three decades. The observed proliferation of R&D tax incentives raises the question of the effectiveness (as well as other potential unknown advantages) of these policy instruments. The purpose of this paper is to carry out an analysis of the reasons (1) why R&D tax incentives became such a popular policy tool and (2) why there was an increase in generosity of this kind of incentives in recent years. As far as the theoretical base for the analysis is concerned, the paper refers particularly to (1) the inter-jurisdictional competition theories relating to tax competition and (2) the (quasi-) public-good nature of knowledge and innovation. The analysis is carried out with the use of the existing data and research on the subject. The results indicate that these are the changes (processes taking place) in the international environment that have considerably stimulated the proliferation and the increase in generosity of R&D tax incentives.

Introduction

Tax incentives for innovation, including in particular the incentives for R&D investments, constitute one of the main instruments for the science, technology and innovation (STI) policy. Although there are advanced

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

economies that still do not offer any tax arrangements for innovation (e.g., Estonia¹, Germany, New Zealand and Switzerland), R&D tax incentives can be regarded as universally used. The availability and generosity of these incentives have increased significantly, both in a long-run perspective (i.e., since the mid-1980s.) and over the past decade (see OECD, 2014, pp. 164-169; Westmore, 2014, pp. 126-127). The observed proliferation of various types of tax incentives for innovation as well as the increase in their generosity raise a question about the reasons for such a state of affairs. The answer to this question is all the more puzzling if one takes into account the fact that tax incentives for innovation – as indirect policy instruments – seem not to be more effective than direct policy tools, and their use may involve significant risks (described later in this article). The purpose of this article is to analyze the potential factors stimulating the increasing prevalence and generosity of the most popular tax incentives for innovation.

While reviewing the existing tax incentives one can observe that in recent years countries have become more creative in using novel incentives to spur research and innovation² (compare Atkinson, 2012, p. 172). However, these are the R&D tax incentives (and among them the R&D tax credit) that are the most commonly used. For this reason, as well as for the reason of data availability, the analysis carried out in this paper is delimited to the R&D tax incentives, with a particular focus on the R&D tax credit.

Methodology and structure of the research

The article addresses the reasons for proliferation and increasing generosity of R&D tax incentives. As a growing prevalence of a given policy tool is usually related to the advantages of its use, and in particular – to its effectiveness, the first problem analyzed in this paper addresses the relationship (and more precisely – the disparity) between (1) the effectiveness of the implementation of R&D tax incentives and (2) the increasing preva-

¹ It is worth mentioning that Estonia, despite the lack of tax incentives for innovation, achieved the largest increase in innovative performance among the European Union member states over the period 2006-2013 (European Commission, 2014b, p. 20).

² 'For example, some countries – including Denmark, the Netherlands, and Norway – have begun to extend R&D tax credits to cover process R&D activities, effectively extending the R&D tax credit from goods to services industries as well. [...] Several countries have recently adopted or expanded tax incentives designed to spur the commercialization of R&D. These incentives [...] allow corporate income from the sales of patented products (or in some cases from innovation-based products) to be taxed at a lower rate than other income' (Atkinson, 2012, p. 172).

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

lence and generosity of this policy tools. The analysis is carried out with the use of the existing data and research on the subject. At this point, it is necessary to emphasize that the disparity indicated above is closely connected to the methodological approaches used while evaluating the effectiveness of the R&D tax incentives. The results of the existing evaluations of the R&D tax incentives effectiveness³ that are used for the analysis, represent a method based on a comparison between the amount of incremental industrial R&D and the loss in tax revenue.⁴ ‘The implicit assumption in this method is that the size of the subsidy has been determined and that the only question to be answered is whether it is best administrated as a tax credit or a direct subsidy’ (Hall & Van Reenen, 2000, p. 457).

The analysis carried out in the first part of the paper leads to a formulation of a hypothesis that the increased prevalence and generosity of the R&D tax incentives has been caused mainly by changes (or factors) external to the economic systems of individual countries, that is, by the changes in the international environment.

The second part of the article is devoted to the verification of the hypothesis presented above and contains the analysis of the factors that might have influenced the process of proliferation and the increasing generosity of R&D tax incentives. The analysis is carried out through the lens of the changes taking place in the international economy (listed later in this article), with the use of existing data and research.

As far as the theoretical background is concerned, the analysis, on one hand, relates to the inter-jurisdictional competition theories that focus on tax competition. On the other hand, it relates to the fact that technology and innovation have some characteristics of a public good (even though they can hardly ever be regarded as pure public goods). The basic downside of tax competition is that attempts by governments to attract (a given kind of or various kinds of) business investment may lead to inefficiently low levels of local public goods, termed in the literature as ‘under-provision’ of public goods or ‘allocative inefficiency’ (compare Lee, 2009, pp. 9-10). However, once the tax competition is directed at attracting investments to the R&D sector, it may at the same time positively influence supply of public goods (through the stimulation of technology and innovation development that – as it was mentioned above – are quasi-public goods). Moreo-

³ Covering mainly the effectiveness of the R&D tax credit.

⁴ B. Hall and J. Van Reenen (2000) provide a detail description of possible approaches to evaluating the effectiveness of any tax policy designed to correct the insufficient supply of quasi-public goods.

ver, the R&D financed by the state indirectly by the implementation of tax breaks may lead to the creation of a radical innovation and thus positively influence the state budget through other channels than corporate taxes.

On a more general level, the analysis of the factors that might have influenced the process of proliferation and the increasing generosity of R&D tax incentives is rooted in (1) the growth theory approaches for explaining the relation between growth and technology, that is: the neoclassical approach and the neo-Schumpeterian (evolutionary) approach⁵; (2) the concept of international competitiveness of countries, developed by, *inter alia*, X. Sala-i-Martin et al. (2013, pp. 3-51) and indicating innovation as one of the most important competitiveness factors.

Proliferation and generosity of R&D tax incentives versus their effectiveness and the balance of potential benefits and risks

The proliferation of R&D tax incentives and their increasing generosity raise expectations that (1) these policy instruments (in comparison with other policy measures) are characterized by better effectiveness and/or (2) there are some unique advantages of using them or the potential risk associated with their use is lower. The aim of this section is to check whether these expectations coincide with the reality.

The existing research results on the effectiveness of R&D tax incentives, in most cases, confirm that these policy tools are effective.⁶ However, they do not indicate that R&D tax incentives are characterized by any outstanding performance. That is to say, it is possible to achieve similar level of effectiveness through implementation of other policy tools. A literature overview concerning the effectiveness of R&D tax incentives⁷ is presented by B. Hall and J. Van Reenen (2000); they indicate methodological weaknesses of individual studies, as well as present their own research results. In general, Hall and Van Reenen confirm that fiscal incentives fulfill the function of R&D stimulators and conclude that 'a dollar in tax credit for R&D stimulates a dollar of additional R&D' (Hall and Van Reenen, 2000, p.

⁵ Although these are competing approaches, they agree on basic issues such as the importance of technology and innovation for economic growth, as well as the positive role that can be played by government policy for science and technology (Verspagen, 2006, p. 492).

⁶ The effectiveness of R&D tax incentives is dependent not only on the method of its evaluation but also on the design of R&D tax incentives (for details concerning the relationship between design and effectiveness see e.g. Elschner et al., 2009).

⁷ Focusing mainly on R&D tax credit.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

449). However, it is worth pointing that the conclusion cited above constitutes also a kind of evidence that the tax credit for R&D (which is the most popular among fiscal R&D incentives) cannot be regarded as a more effective R&D stimulator than direct policy tools. The dollar which a given state is losing in taxes (because of the implementation of R&D tax incentives) is simply spent on a given firm's R&D project. Hence, it is almost the same as in case of – for example – R&D grant: one dollar granted to a given firm with the aim to support some R&D project reduces the budget of a given state by 1 dollar. In this case, the only arguments in favor of the implementation of the R&D tax incentives (instead of direct measures) are: the fact that private companies have usually better knowledge (or intuition) concerning successful projects (so that they make better choices), as well as the fact that the administrative cost of the implementation of indirect measures is lower than in case of the direct ones. However, direct measures are more likely to support projects with a higher social rate of return (Bérubé and Mohnen, 2009, p. 207), and that can constitute a kind of 'recompense' for the downsides mentioned above.

What the above indicates is that the increasing prevalence of R&D tax incentives cannot be explained by their unique effectiveness.⁸ It is all the more so, if one takes into account the fact that there are also less optimistic studies as far as the effectiveness of tax R&D incentives is concerned; for instance, C.-H. Yang et al. (2012, p. 1586) indicate that:

'The R&D preferential policy of a tax credit has indeed induced additional R&D investment undertaken by firms in Taiwan, while the R&D-enhancing effect is much lower compared with experiences in developed countries surveyed by Hall and Van Reenen (2000). This casts the susceptible view regarding the effectiveness of R&D tax credit policy from the view of public finance.'

In addition, there are also studies finding that one euro of foregone tax revenue on R&D tax credits raises expenditure on R&D by less than one euro (for examples of such studies see: European Commission, 2014a). Apart from that, the empirical studies that compare the effectiveness of R&D grants and tax credits give ambiguous results; for example:

⁸ However, one should remember that the methodology of the R&D tax incentives effectiveness evaluation does not refer to the potential social return from R&D whereas, for example, J.W. Fedderke and B.G. Teubes (2011, p. 1787) argue that 'it is possible that the social return from R&D might be sufficient to allow R&D incentives to more than pay for themselves'.

‘A firm level research of Norwegian firms conducted by Hægeland and Møen⁹ suggests that tax credits appeared to have a slightly larger effect than direct support measures [...]. Empirical findings from a panel of 19 OECD countries¹⁰ indicate that direct support seems to have a larger impact than (volume-based) R&D tax incentives [...]. Instrument design and implementation might be more important determinants of additionality than whether the instrument is a direct subsidy or a tax incentive’ (European Commission, 2014a, p.39).

As the effectiveness of R&D tax incentives does not explain the reasons for their increasing prevalence and generosity, there is a question whether these instruments are characterized by unique advantages and/or whether the risk associated with their use is smaller than in case of direct measures. When a government decides to implement R&D incentives, then it has a wide range of instruments to choose, as tax incentives are only one way of stimulating the amount of R&D undertaken within the country. The use of all the potential R&D stimulators has its advantages and disadvantages, and the R&D tax incentives seem not to be any exemption (i.e., any distinguishing instrument) in this respect.

A. Carvalho (2012, p. 125) presents a brief literature overview on the pros and cons of R&D tax incentives in comparison with direct policy measures, and the OECD publications provide numerous descriptions of the risks associated with the use of these instruments (see, e.g., OECD, 2014, p. 164). The list of the most important downsides of R&D tax incentives, *inter alia*, includes (Carvalho, 2012; OECD, 2014; Busom et al., 2014):

- Greater (than in case of direct measures) risk of so called dead weight loss (i.e., risk of supporting projects which would have been carried out anyway);
- Risk of enterprises relabeling other activities as R&D;
- Risk related to the fact that private firms are likely to choose R&D projects with the highest private rate of return (whereas it would be desirable to spend public money on R&D research projects with the highest social rate of return);
- Risk related to high unpredictability as far as the amount of ‘tax loss’ is concerned, which means that governments, while using the instrument, face the problem of poor budget control;

⁹ Hægeland & Møen, 2007.

18-19 June 2015, Economics and Finance**

- Risk of tax competition for R&D that could result in a zero-sum game at international level, and thus reduce government revenues in all countries involved.

Appendix 1 contains a comparison of advantages and disadvantages related to the use of tax incentives and direct measures. Briefly, it can be said that the pros and cons of using R&D tax incentives, in comparison with direct policy measures, do not explain the phenomenon of proliferation and increasing generosity of R&D tax incentives. Only the risk of tax competition created by the use of R&D tax incentives indicates that the popularity of these policy tools may be caused by factors that are external to the economic systems of individual countries and induced by the changing international environment.

**The increasing prevalence and generosity of R&D tax incentives
versus the changes in the international environment**

Some of the important factors that influenced the development of R&D tax incentives (as the STI policy tool) could be described as external to the economic systems of individual countries, because they are related to the changes in the international environment. These changes include: advancing globalization (and the associated trade liberalization), increasing FDI flows, regional integration of countries and the increasing role of innovation (and consequently – innovation policy) in the countries' economic development. The changes indicated above resulted in an additional set of factors for the implementation of R&D tax incentives by the national governments, and thus led to the increasing prevalence and generosity of these incentives.

The first factor influencing the development of R&D tax incentives is closely related to the globalization and regionalization processes and the growing importance of the foreign direct investment (FDI) inflows in the economic development of countries. On one hand, the globalization (and regionalization) of the world economy have made FDI incentives more important from the national governments' economic policy point of view.¹¹ On the other hand, the globalization and the accompanying trade liberalization have reduced the importance of market size as a factor determining the

¹¹ The increasing prevalence of investment incentives as a tool to attract FDI took place in the 1990s. As a result, in the mid-1990s more than 100 countries have already provided various investment incentives, and their number has been increasing rapidly (see Blomström & Kokko, 2003, p. 4).

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

location of FDI. As a result, even small countries have gained the opportunity to successfully compete for FDI, provided they focus their actions on other FDI determinants, including the implementation of an attractive set of incentives. In consequence, the number of countries competing for the inflows of FDI considerably increased, and thus the competition became more intense. Moreover, the countries competing for inward FDI often try to attract the inflow of FDI to the R&D sector, as such investments are regarded to be the most profitable, because of the potential transfer of knowledge and/or technology.¹² From this point of view, R&D tax incentives can play a double role, that is, not only the role of R&D investment incentives (implemented to encourage domestic companies to develop R&D activities) but also the role of incentives for FDI in the R&D sectors.

The above processes and factors influence the generosity and proliferation of R&D tax incentives. They are closely related to one of the downsides of R&D tax incentives implementation, i.e.: the risk of tax competition between regions and/or countries. So, paradoxically, the generosity and popularity of R&D tax incentives is related, *inter alia*, to the development of its negative feature. It is the more so, as there is also one more reason for the R&D tax competition. The globalization and regional (or interregional) integration processes in the world economy made it much easier for the domestic companies to move their businesses abroad in a situation when the cost of running a particular business in another country is lower. Because of that, the R&D tax incentives may also be used to prevent the potential transfers of innovative domestic companies to other countries.

The process of regional integration in Europe that led to the establishment of European Union (European Communities), contributed to the emergence of another factor which influenced the increasing R&D tax incentives prevalence and/or generosity. This factor is related to the creation of innovation policy, coordinated at a supranational level. The policy guidelines formulated within the framework of the European Union innovation policy – because of their supranational character – can be regarded as an additional external factor that contributed to the development of R&D tax incentives in Europe. In 2000, the European Union member states launched the Lisbon Agenda that, *inter alia*, called for an increase in R&D expenditure (up to 3% of GDP), with a special focus on the private share of R&D expenditure which was to reach two thirds of the total expenditure by

¹² The experiences of Intel provide a good example of such competition. R.D. Atkinson and S.J. Ezell (2013, p. 174) describe the incentives offered by Israel, India, Vietnam and China in order to attract this multinational company.

2010. R&D tax incentives, as policy instruments stimulating private R&D expenditure, appeared to be useful as far as meeting the above innovation policy guidelines is concerned (compare Carvalho, 2012, p.128). Nevertheless, not all the countries managed to meet the objective set out in the Lisbon Agenda; some of them still have a low level of R&D expenditure and/or a relatively small private share of R&D expenditure. Hence, taking into account the fact that the strategy 'Europe 2020' (which replaced the Lisbon Agenda) as well set the target for the EU member states to invest 3% of GDP in R&D (and that private R&D investments are regarded to be better than public), the policy effect, stimulating the R&D tax incentives development in the European Union, still exists. Of course, similar stimulating effect can be also achieved at the national level by setting ambitious goals as far as the level of private R&D investment is concerned.

Conclusions

This article explores the reasons for the increasing prevalence and generosity of R&D tax incentives. The analysis carried out in the paper partly confirmed the hypothesis that the increased prevalence and generosity of the R&D tax incentives has been caused mainly by changes (or factors) external to the economic systems of individual countries, that is, by the changes in the international environment.

There is no doubt that the changes (processes) taking place in the world economy – such as: advancing globalization, increasing FDI flows, regional integration of countries, the increasing role of innovation in the countries' economic development – influenced the growth of prevalence and generosity of R&D tax incentives. These changes resulted in an additional set of factors for the implementation of R&D tax incentives by the national governments, and thus stimulated the proliferation and generosity of the above instruments. First of all, some of the changes contributed to the emergence and/or intensification of tax competition, and the tax competition led to the increased generosity and prevalence of R&D tax incentives. Furthermore, in case of European Union, the coordination of innovation policy at a supranational level appeared to be an additional external factor for proliferation and increasing generosity of R&D tax incentives in Europe. Nevertheless, it cannot be taken for granted that the changes in the international environment constituted the main cause for the proliferation and generosity of R&D tax incentives, as the decisions of the national governments concerning the implementation of R&D tax incentives could be also related to

**Proceedings of the 8th International Conference on Applied Economics

18-19 June 2015, Economics and Finance**

the believe that the social return on innovation was so high that it exceeded the tax loss related to R&D tax incentives implementation (and thus there was no need to take into account other potential advantages of this policy instrument).

The Role of the State in Creating a Green Economy

JEL Classification: *E12; F62; F63; F64; O20; O38; O44; P48; Q01; Q28; Q30; Q32; Q43*

Keywords: *sustainable development; environment; state; a green economy; energy*

Abstract: Starting from the crisis on the real economy in 2008 it has been developed an intense discussion, supported by a number of declarations on the global scale, about the need for changes in the economy. A huge impact on this state of affairs was the analysis of the causes and effects of the economic downturn and the challenges of the future. As a result, some states have taken action to remedy the situation. Many of them were aimed at structural changes in production, consumption and environmental friendly investment. At the same time gained in importance the concept of "low carbon economy" and "green economy".

The aim of this paper is to present the role of the state in the economy in terms of creating conditions for a green economy. The thesis of publication is: implementation of structural changes connected with creating a green economy requires the involvement of the state.

Introduction

As a result of the crisis 2008-2010, there were raised voices regarding the need for changes in both the basic paradigms of modern economics, as well as the structural framework of national economies. In the first case a

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

dispute flared up between opponents and supporters of liberalism. With regard to the second issue has gained in importance of the green economy concept. This is an economy based on the reduction of energy consumption, based on traditional energy resources, increasing energy and resource efficiency and increasing the share of energy from renewable sources.

Intensive efforts for green economy were taken especially in the United States. Green economy has also become one of the elements of the anti-crisis program adopted in the European Union. As justification for the introduction of structural transformation to a green economy can be identified: building new competitive advantages, the use of research potential, environmental considerations, the creation of new development framework. Creating a green economy, however, faces some obstacles: low demand for green products and services, higher cost of production of such goods, playing down the role of increased efficiency in the use of natural resources.

The purpose of this paper is identification states role in creating of a green economy.

Methodology of the research

The research method is based on the analysis of strategic documents, anti-crisis plans, measures taken by the state, as well as examples of practical actions initiated by countries, in terms of the real possibilities of implementation. At the same time it presents guidelines for the implementation of the state policy in the field of creation of a green economy introduced by international organizations.

The role of the state in the economy

After several decades dominated by the neoliberal doctrine, espousing reduce the role of the state in the economy, the crisis 2008-2010 revealed weaknesses of its assumptions. The sources of the crisis are justified both in the doctrinal concept, as well as the structure of the economy. No less important role played implications of market weakness. According to professor Grzegorz W. Kołodko: "Only the power of intelligent synergy with invisible hand of the market and the visible head of state creates opportunities for far-reaching economic success" (Kołodko, 2010, p. 95).

The state plays an important role in correcting scarcity of the free market in areas (Winiarski, 2006, pp.31-32):

- raising the efficiency of the economy in a societal scale,

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

- limit excessive inequalities in the distribution of the social product,
- stabilizing the economy.

There are also emphasized (Czaja, Becla, 2012, p. 134):

- the need for regulation in the economy,
- the existence of market failures in the competition,
- the existence of external effects.

Some of them revealed due to the economic crisis 2008-2010 especially in banking and financial sector. The effects of the crisis were the result of agreement for financial system to live its own live, because of limited regulations of innovation in that area (Flejterski, 2010, p. 138).

The state is obligated to ensure appropriate living conditions of citizens. That means not only working and livings opportunities, but also environmental quality. That have to be done through public concern about these elements, because of the enterprises activity and their pursuit of profit, which can be unrestricted, especially in use of the natural resources. This infinitive must be subjected to a rationalization. And that is, among others, the reason for which underlines the issue of sustainable development, defined as: "development that meets the needs of the present without compromising the ability of future generations to meet their own needs" (*Our common future*, (http)).

Significant is also quite common opinion, that the state is the largest economic entity, which regulates the functioning of other actors and institutions (Kaczmarek, 2004, p. 87). This conclusion corresponds with other: "We need a smart combination of the principles of economic freedom with a pragmatic, resulting from the principles of rationalism role of the state and the appropriate scope of the public sector" (Żyżyński, 2010, p. 41).

It should be emphasized that as a result of globalization, there appear new threats, which, because of its scope, require the active role of the state (Dach (ed.), 2008, pp. 16-17):

- environmental hazards, f. ex. destruction and environmental pollution, climate change;
- economic risk;
- social risk - increase in unemployment, poverty and hunger.

In some areas the role of the state is marginalized because of internationalization of economic relations and trade liberalization. On the other hand, it causes many negative effects and their limitation is possible only in cooperation of the states. This particularly applies to environmental issues.

A Green Economy – definition and main goals

The concept of a green economy has gained in importance as a result of the crisis of the real economy, which started in 2008. Its genesis dates back to 1989, when it was used for the first time in the report "Blueprint for a Green Economy", prepared for the Great Britain government (*Blueprint for Green Economy*, London, 1989). A green economy is linked to the reduction of energy consumption based on traditional energy resources, increase and resource efficiency and increase the share of energy from renewable sources. Presently is identified with the reduction of energy consumption, based on traditional energy resources, energy and resource efficiency, growth the share of energy from renewable sources.

The concept was mainly developed in 2008 and 2009 by international organizations such as the United Nations Programme for the Environment (UNEP) and the Organization for Economic Cooperation and Development (OECD) through various programs, reports and declarations. One of the most important paper in this issue is New Economics Foundation report "A Green New Deal", which indicated the need to overcome the "triple crunch" crisis: financial, associated with climate changes and the crisis resulting from high oil prices (*A Green New Deal*, 2008). Please note that never before such proposal, based on establishing a direction for economic development strongly associated with environmental considerations, not gained such importance, as in the case of the recent crisis. Although, a milestone in this issue was Brundtland Commission report – "Our Common Future" (1987) and establishing the principle of sustainable development (*Our Common Future*, 1987).

Explaining the reasons for this situation will help answer the question of what is a green economy. According to working definition, prepared by United Nations Environment Programme (UNEP), a green economy "results in improved human well-being and social equity, while significantly reducing environmental risks and ecological scarcities. In its simplest expression, a green economy can be thought of as one which is low carbon, resource efficient and socially inclusive" (UNEP, ([http](http://))). It is emphasized, that it can be regarded as a more pragmatic approach to the implementation of sustainable development (Burchard-Dziubińska, 2013).

Creating a green economy is aimed at achieving the following objectives (Szyja, 2013):

- increase of energy and raw materials efficiency,
- reduction of greenhouse gases (especially carbon dioxide),

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

- reduction of the level of pollution resulting from production processes,
- increase energy security,
- mobilizing the potential of innovative,
- acquiring new competitive advantages.

Implementation of these purposes is linked to the performance of green industrial revolution, that will generate global demand and create jobs, inter alia, through the development of clean and efficient technologies, increase the use of renewable energy, promotion of environmentally friendly transport systems (Szyja, 2011, p. 72).

In this sense a green economy includes the following elements:

- green products and services,
- green investments,
- green sectors of the economy,
- green public procurement,
- green tax reform,
- green jobs.

The first one group are products, that throughout the life cycle have a limited impact on the environment. Green investments are related to the energy self sufficient constructions or energy, raw materials efficient machines and equipments. It have been proposed to investment in natural capital, sustainable agriculture, human capital, infrastructure, innovation (Allen, 2012, p. 7).

In turn, green sectors of the economy are not only agriculture, forestry, and animal husbandry, but especially renewable energy, the production of environmentally friendly technologies.

Green public procurement, according to the European Commission, is “a process whereby public authorities seek to procure goods, services and works with a reduced environmental impact throughout their life cycle when compared to goods, services and works with the same primary function that would otherwise be procured” (*Public procurement for a better environment*, 2008, p. 4).

Green tax reform can help to cut down environmental externalities through appropriate structures of tax rates, tax exemptions (Aidt, 2010, pp. 31-43).

According to the International Labour Organization green jobs are those that (Szyja, 2013, s. 199):

- contribute to reducing the consumption of energy and natural resources,
- reduce greenhouse gas emissions,

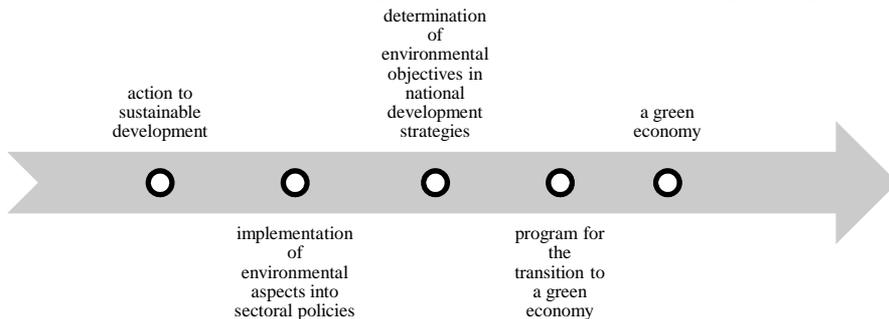

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

- reduce the amount of waste and pollution,
- foster the protection of ecosystems and restore their original state.

As Edward B. Barbier emphasized: “Transitioning to a green economy requires a mix of short- and long-term policies, a different mix of policies and instruments for rich as opposed to poor countries, and overcoming the political difficulty of implementation”(Barbier, 2012, s. 887). In turn Cameron Allen (UN Division for Sustainable Development) argues that, therefore, national governments should adopt their own definitions of a green economy in accordance with national priorities and circumstances (Allen, 2012, p. 3).

The success of the specific elements of a green economy depends on the involvement of three groups of actors, that means states, businesses and societies in their commitment to implement. A particularly important role is played by the first one, because of the tools and instruments that are available to and associated with the formation of economic policy. No less important is the process to achieve a state of the green economy, which requires a systemic approach (picture 1).

Picture 1. Phases on the way to a green economy in the context of planning

Source: Author's own

Most European countries have implemented some elements of sustainable development principle, both in terms of planning solutions, as well as through specific practical ones. However after crisis have been proposing green growth policy toolkit, which includes a step-by-step guide, for example four categories of policy tools, promoted by international institutions (AfDB, OECD, UN, World Bank, 2012, p. 17):

- Incentivize - tools for pricing pollution and natural resource use, tools to complement pricing policies, tools to foster inclusiveness;

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

- Design - tools to manage uncertainty;
- Finance – financing and investment tools;
- Monitor – monitoring tools.

**Overcoming the crisis through the development of
a green economy**

Because of the crisis on the U.S. mortgage market, states were obliged to counteract. This public commitment was something new in the face of neoliberal mainstream with the release of Milton Friedman. This occurred as a result of public disillusionment arbitrary enterprises and limited regulatory systems of financial markets. In these circumstances, some countries adopted anti-crisis programs. Furthermore politico-economic union like the European Union did made the same step to overcome the negative effects of the economic downturn. A new and simultaneously element of these plans were measures, aimed at structural transformation of economies to more environmentally friendly. This course of states involvement was justified by the following arguments:

- reduce the potential for similar events in the future;
- meet the challenges of the future such as: energy crises, climate changes;
- create new capabilities for the development of economies;
- development of innovation potential associated with clean technologies;
- reduce the addiction to natural resources, especially petroleum, gas;
- increase the efficiency of production processes;
- create new jobs;

Below will be given examples of activities taken in this particular aspect.

January 8, 2009 President Obama announced “The American Recovery and Reinvestment Act”. The value of the anti-crisis plan was 787 billion USD, of which nearly 80 allocated to projects connected with clean energy. Direct expenditures have been focused especially on: energy efficiency, reduce pollution of air and water, modernization of the power grid, reduce carbon dioxide emissions, transport, research and innovation, renewable energy sources. Mentioned funds have been transferred to government agencies, state authorities, scientific institutions and company, in the form of loans, guarantees, grants.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

It is worth mentioned a few examples of projects. There have been developed project under the Department of Energy called SunShot, which aims to reduce the price of solar power to 1 USD / watt (up to 75%) in 2020 through advance in systems that convert light energy (photovoltaic technologies), increase productivity and optimize the use of solar and streamline procedures for obtaining permits for solar energy systems. Another instance is Clean Cities Program, covering nearly 100 cities. It has been designed to reduce the consumption of traditional liquid fuels and increase the use of renewable fuels and develop new technologies in the field of transport. In turn, DOE's Advanced Technology Vehicle Manufacturing (ATVM) encourages companies in the expansion of production facilities for electric vehicles.

In addition to the funds it have been started to develop standards for example for fuel consumption and emission:

- introduce new requirements for car models from the years 2012 to 2016. In 2016, the cars have to pass no less than 35.5 miles per one gallon of gasoline, it is almost 15 km per 1 liter (6.7 liters per 100 km),
- set measure for medium and heavy truck models 2014-2018,
- introduce The National Emissions Standards for Hazardous Air Pollutants for Utility Boilers.

Furthermore there have been established economic goals, connected with environment for the implementation through 35 federal government agencies (Szyja, 2013, p.154):

- reduce fuel consumption by 2020 by 30%,
- reduce of water consumption in the economy for 2020 by 26%,
- increasing to 50% the proportion of waste recycled as early as 2015,
- growth share of public contracts which meet the requirements of a balanced and sustainable development to 95%.

“The European Economic Recovery Plan”, announced at the end of 2008, has highlighted the need of a coordinated action at national and the EU levels respond to the economic crisis. The EERP was based on two pillars, one related to fiscal policy, the second to the direct structural transformation. Thus, the first was connected with the Pact for Stability and Growth, and the second with the Lisbon Strategy. One pillar have been focused on boosting the economy in the short term by an immediate budgetary impulse amounting to 200 billion EUR. The second has been concerned the orientation of "short-term action to reinforce Europe's competitiveness in the long term". In this regard, it has been undertaken development of "smart investment", which means investing in growth of energy

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

efficiency to create jobs and save energy; investments in clean technologies in order to promote, among others, the construction sector and the automotive industry. The Plan has also identified an important number of green initiatives with a focus on energy-saving and climate-change related measures. In this last means each efforts should have been focused on greening the economy through involvement in two areas, development of green energy infrastructure and energy efficiency. For energy projects in the period 2009-2010 was booked 3,980 billion EUR, respectively for gas and electricity infrastructure (2,365 billion EUR), offshore wind farms (565 million EUR) and the capture and storage of carbon dioxide (1.050 billion EUR) (*Driving European Recovery*, ([http](#))). At the same time it has been modified regulations, which allow for an increase of up to 8 billion EUR for investments in energy efficiency and renewable energy in residential buildings (*European Parliament legislative resolution of 6 May 2009*, ([http](#))).

Some member states adopted their own anti-crisis programs, including “green” elements of recovery instruments. It was possible, because of launching legislative and financial instruments on the EU level for example (Szyja, 2012, p.184]:

- consensus, among governments of the member states and the European Bank Investment, on loan guarantees and loans of innovative eco-products,
- use of the European Cohesion Fund to finance thermo-modernization and renewable energy source of buildings in all member.

According to the European Commission, the total sizes of the "green" parts of states packages differed between countries. The share "green" efforts ranged from 1.3% in Italy to 13% in Germany, and 21% in France. In most cases the 'green' elements was identified with energy efficiency, renewable energy, development of public transport and infrastructure and car scrapping schemes. In form of the type of instrument, member states used public investment, loans and loan guarantees, and subsidies (*Non paper „Green elements from member states recovery plans”*, ([http](#))). For example significant amount of anti-crisis package in Belgium, Czech Republic, Estonia, France, Slovenia, Germany, Spain was allocated to increase of energy efficiency in buildings. In turn Denmark put on green transport, Finland on green technologies, Portugal on energy from renewable sources (*Green Growth: Overcoming the Crisis and Beyond*, 2009, p.15-18). In Poland, the government did not indicate in the package directions of actions and instruments to assist the implementation of structural transformations strictly

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

to the "green economy". Indirectly pointed to the need to accelerate investments co-financed from EU funds, which concern, inter alia, solutions to municipal and supporting renewable energies.

States involvement in the area of creating a green economy due to several reasons. The first one refers to strategic dimension of projects mainly in the energy sector. This is connected with energy security and attempts to be independent of gas or oil supplies from abroad (table 1.).

Table 1. Energy dependency rate, EU 28, 2008-2012 (% of net imports in gross inland consumption and bunkers, based on tones of equivalent)

Specification	2008	2009	2010	2012
Crude oil	84,9	84,1	85,1	88,2
Natural Gas	61,7	63,4	62,1	65,8

Source: EUROSTAT

http://ec.europa.eu/eurostat/statisticsexplained/index.php/Energy_production_and_imports

It should be emphasized, that between 2008 and 2009 import of crude oil declined, however it was short-lived as well as a decrease of gas supply in 2009 and 2010. In 2013 import of oil from different regions of world was in EU on the level: former Soviet Union - 39,8%, Europe - 18,76 %, America - 4,61%, Africa - 24,05%, Middle East - 12,89% (*Market Observatory for Energy*, 2014).

The second one is the high capital investment. It is due to the high costs and long payback period. Following is connected with little companies interest due to the high investment costs and uncertain benefits, especially in sectors related to environmental technologies and renewable energy (*The Global Environmental Goods and Services Industry*). According to World Economic Forum public action can help to introduce additional capital through other financing mechanisms by absorbing potential losses to other financiers, as well direct equity investment from the public sector can be valuable for projects with heightened technology risks (*The Green Investments Report*, 2013, p. 77).

Next the states have more possibilities to invest in research than individual companies, because of due to the financial possibilities and relationships with scientific centers (Vaitilingam,(http)).

Another one points to empower the public to the attitudes and behavior more environmentally friendly. This requires education from first class in primary school. "Individuals must be ready to learn, to change their habits" (Kink, Reinumägi, 2011, p. 183).

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

No less important is to reinforce consumers with various kinds of subsidies, which would encourage them to buy green products and services. As well states should arrange solutions for entrepreneurs to invest in more sustainable production.

And the last one is the need to introduce some structural changes in economy – greening up economy. That means not only development of green sectors, like renewable energy or green technologies, but also introducing ecological transformation of traditional sectors like automotive. For example, in the United States the government addicted state assistance for General Motors and Chrysler, inter alia, from the introduction of efficiency technologies in production processes and environmentally friendly vehicles, which would be offer buyers. However, this example shows a conditional form of state influence on the company. It is also important to carry out the transformation of the economy and the individual sectors because on the one hand to external factors f.ex. climate change and on the other the pursuit of commercial entities to make profits through new types of products and services. It is essential noticing, both the need for and benefits of changes aimed at environmentally friendly solutions.

International organizations, in many publications, indicate specific solutions for the implementation of a green economy. OECD stresses the need for action in two areas: reinforcing economic growth and the conservation of natural capital, encompassing policies targeted at incentivising efficient use of natural resources and making pollution more expensive. Both require such activities as fiscal and regulatory settings (f. ex. tax and competition policy) and a mix of price-based solutions (OECD, 2011, pp. 11-12). UNEP highlights prioritising government investment and spending in support of a green economy, limiting government spending in areas that deplete natural capital, using taxes and market-based instruments to promote green investment and innovation, and investing in capacity-building, training and education. And UNESCAP emphasize the need of reforming the economic incentives framework, promoting sustainable infrastructure investment, and facilitating investment in natural capital (Allen, 2012, p. 6). World Bank divide green growth policies into three broad categories: the “getting the price right” policies; the “complement or replace prices” policies where markets signals can’t be relied upon to effect the desired changes; and “activist” policies such as innovation or industrial policy (World Bank, 2011, p. 23).

Also remarkable is to reach, on an international level, an agreement for green growth. The green growth is identified by "green investments", based

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

on the development of technologies for the use of energy efficiency and reduce carbon emissions (*Declaration on Green Growth*, 2009). It is essential to create more effective climate change policy. However at the same time it should be pointed to “green race” in the production and sale of environmental technologies, primarily related to renewable energy. In this race are involved mainly The United States, China and German. Especially the second one is characterized by high growth of wind energy capacity (IEA, 2013, p. 10). It is possible due to the involvement of the state through measures like production subsidies and export support, which was a subject of petition of the United States in WTO. In many cases it is a serious threat for companies from other countries, particularly in USA. They need support from the state to compete. At the same time the involvement of the state may result of the public policy and (Henzelman, Schaible, Stoever, Meditz, 2011, pp. 33-34):

- accelerate the development of selected environmentally friendly technologies through R & D activities,
- accelerate the market introduction of modern but expensive products in order to benefit,
- create companies in the green sector,
- form of response to international agreements.

In the declaration of Rio +20 have been noted, that the green economy have to be implemented by public policies, each country can choose an appropriate approach in accordance with national sustainable development plans, strategies and priorities which should include, inter alia (*Report of the United Nations Conference of Sustainable Development*, 2012, p.11):

- respect each country’s national sovereignty over their natural resources taking into account its national circumstances, objectives, responsibilities, priorities and policy space with regard to the three dimensions of sustainable development;
- be supported by an enabling environment and well-functioning institutions at all levels with a leading role for governments and with the participation of all relevant stakeholders, including civil society;
- promote sustainable consumption and production patterns;
- continue efforts to strive for inclusive, equitable development approaches to overcome poverty and inequality;

In Author opinion the main obstacles in introducing green economy is to overcoming the gap between expenses incurred in the short term for environment friendly investment and the economic and social benefits achieved in the long term. In this regard, the state should take action to convince

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

companies and the public to make the effort now incurring expenditure, which will bring the desired results in a long time.

Conclusions

A green economy can be identified with new direction of development. It should be emphasized that many in this field has already been done, mainly because of anti-crisis programs, which were introduced to overcome the effects of the economic downturn.

The role of the state in the development of a green economy is essential, because of its instruments and measures, which are necessary for shaping supply and demand in the field of environmental solutions. Both consumers and producers require support, because of high cost of green technologies, energy from renewable sources and green products. At the same time, there is need to finance research and innovation to lower price of such goods. The future of green economy depends also on global commitment on climate changes and ways of dealing with them, which depend on the cooperation of the states.

The further research will concern the involvement of enterprises in the process of transition to a green economy.

**Can Inflation Forecast and Monetary Policy
Path be Really Useful? The Case of Czech
Republic***

JEL Classification: *E52; E58; E61*

Keywords: *inflation forecasts; inflation forecast targeting; policy path; inflation expectations*

Abstract: Producing and revealing inflation forecasts is believed to be the best way of implementing a forward-looking monetary policy. The article focuses on inflation forecast targeting (IFT) at the Czech National Bank (CNB) in terms of its efficiency in shaping consumers' inflation expectations. The goal of the study is to verify accuracy of the inflation forecasts, and their influence on inflation expectations. The research is divided into four stages. At the first stage central bank credibility is examined. At the second stage – accuracy of the inflation forecasts. The next step covers a qualitative analysis of IFT implementation. Finally the existence of the interdependences of inflation forecast, optimal policy paths and inflation expectations are analyzed. Credibility of the central bank, accuracy of the forecast and decision-making procedures are the premises for the existence of relationship

* The article presents the results of researches financed by the National Science Center: Interdependences of Inflation Forecasts and Inflation Expectations of Market Participants. Implications for the Central Banks contract No.: 2011/03/B/HS4/03705 and Forecasting inflation on the basis of DSGE models in the implementation of inflation targeting in select-ed central banks contract No.: 2013/09/N/HS4/03766.

between forecasts and expectations. The research covers July 2002 - end of 2013. Its methodology includes the qualitative analysis of decision-making of the CNB, quantitative methods (Kia and Patron formula, MAE forecasts errors, quantification of expectations, non-parametric statistics). The results show the existence of interdependences between inflation forecasts and expectations of moderate strength. The preconditions of such interdependences are partially fulfilled. The research opens the field for cross-country comparisons and for quantification of IFT implementation.

Introduction

Modern monetary policy focuses on expectations which are the crucial interest of modern monetary policy. The central banks search for the tools that are helpful in shaping inflation expectations and that enhance their forward-looking attitude. Producing and revealing inflation forecast is such a tool. An ability to guide market expectations can be analyzed in the context of the central bank credibility. The central bank is credible when the private sector believes that the central bank will realize what it said (Mackiewicz-Łyziak, 2010, p. 12). The most obvious central bank declaration is inflation target. When the market expectation are on the inflation target level, the central bank is perceived as credible. The article focuses on the central bank inflation forecasts and consumer expectations. They are analyzed jointly, and the context of inflation forecast accuracy and IFT implementation are added.

The main research question of this paper is whether the households believe inflation forecasts. The hypothesis assumes that inflation forecasts published by CNB in the years 2002-2013 are accurate (1) and correlated with inflation expectations of households (2). The main objective of this research is to verify this hypothesis. The research has a broader context as well. Its starting point is the qualitative analysis of the inflation forecast targeting implementation and examination of the central bank's credibility. These are important preconditions of using forecasts for shaping expectations.

The research presented in the article is the first complex analysis of the inflation forecasts and their usefulness for the consumers and the central bank.

Theoretical background

Modern monetary policy is, and should be, forward-looking. The forward-looking nature of inflation and monetary policy focuses on inflation expectations which are emphasized in modern monetary theory. Its framework is broadly described in the related literature (Mankiw, 1990, pp. 358-360, Goodfriend & King, 1997, pp. 24-40, Galí, 2003, pp. 157-160). The starting point for developing a new neoclassical synthesis model was the price setting model (Calvo, 1983, pp. 384-393), where inflation depends on current inflation expectations and output gap. An expected price level change should be taken into account while readjusting prices, as the economic agents know that it may not be possible to change the prices in the following period. The ability of a central bank to influence expenditure, and hence pricing decisions, is strongly dependent upon its ability to influence market expectations regarding the future path of overnight interest rate, and not merely their current level (Woodford, 2003, p. 16).

The modern monetary policy strategy – inflation targeting – is believed to be the best way to implement a forward-looking, focused on expectations, monetary policy. Inflation forecast produced by the central bank on the basis of theoretical framework is immanent part of inflation targeting which can even become inflation forecast targeting (IFT), where inflation forecast plays the role of an intermediate objective of monetary policy. One argues that ascribing the function of an intermediate target to the inflation forecast simplifies implementing and monitoring monetary policy (Svensson, 1997, p. 1120).

The main reason why the forecasts are revealed is a need to shape inflation expectations of the public. Publishing the inflation forecast may help to guide longer-term expectations. It can serve as a temporary anchor, especially in situations where the target is missed because of shocks that are out of control of the central bank. An anticipated course of inflation, showed by a credible central bank may limit the expectations' growth (Skořepa & Kottlán, 2003, pp. 154-155).

Perceiving the role of inflation forecast in expectations shaping, in the last decade majority of the central banks started to produce and reveal their own inflation (and GDP) forecast.

Inflation forecasts are made on different instrument-rate assumptions. The most important assumptions are: constant instrument rate during the entire forecast horizon (CIR), market expectations of the future interest rate (ME) and endogenous rate. These assumptions imply the different decision-

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

making procedure (CIR - the rule of the thumb, endogenous rate – following optimal monetary policy path). Implementing the optimal monetary policy requires the optimal (specific) targeting rule related with a flexible strategy (target variables for both inflation and the output gap), and operating in a way that expresses the identity between the marginal rates of transformation (MRT) and substitution (MRS). MRS is based on the preferences of Monetary Policy Committee and MRT is based on the structure of the economy (Svennson, 2002, p.p. 773-777). That is why the policy path includes the forecasts of the target variables such as inflation and output gap and instrument-rate path consistent with them. It can be described as the current and future interest rate path that is consistent with achieving inflation target (Svennson, 2003, p.p. 451-460). In the research only the inflation forecasts are analysed and we assume that inaccurate forecasts imply inaccurate policy path.

Methodology of the research

This research focuses on the case of the Czech Republic. The CNB has produced its own macroeconomic forecasts with endogenous interest rate from July 2002. It imposes the starting point of the research.

Table 1. Forecasting inflation in CNB

Feature	Description
DIT introduction	1998
Forecast disclosure	from April 2001
Output	forecast of inflation and GDP, fan chart (inflation, GDP, policy path from 2008 and exchange rate path from 2009)
Policy path	from July 2002 given in descriptive way form 2008 policy path disclosure on the fan chart
Forecast frequency	quarterly: January, April, July, October; from 2008: February, May, August, November
Forecast horizon	first, 6 quarters, then up to 8 quarters
Transmission horizon	4-6 quarters

Forecasting inflation in CNB occurs within the multi-model approach and its whole system is called FPAS. It consists of a vast number of models including auxiliary models, satellite models and one core model. These models have been divided over the forecasting system due to the time horizon. This division covers three periods: short, medium and long term. The result of the forecasting system is a long-term projection of CPI inflation and, since 2008 also core inflation projection (MPRI). The components of the whole system are given in Table 2.

Table 2. The components of the FPAS

Horizon	Type of model
Short term	<i>Monitoring and Near-Term Forecasting Models</i>
	<i>Signal extractions models</i>
Medium term	<i>DSGE model g3</i>
	<i>Dynamic Optimizing Multisector Model with Stock-Flow Relationships</i>
Long term	<i>Satelite models</i>

IV	Interdependences of inflation forecasts and inflation expectations of consumers	Non-parametric statistics for forecasts and expectations

Source: own work.

The research on the inflation forecasts of the CNB is divided into four specific steps which are shown by Figure 1.

Figure 2. Kia and Patron formula

Source: own calculations.

At the first stage, the credibility of the CNB is analyzed. The credibility is understood as the fulfillment the central bank's formal declaration - inflation target. This fulfillment was checked on the basis of calculating the mean absolute deviations of past inflation from the inflation target. The study includes two measures. The first one is a simple absolute deviation of inflation from the inflation target, as follows $|\dot{y} - \pi|$, where \dot{y} is inflation rate and π is the inflation target. The authors have adopted their own interpretation of the deviations of the inflation from the inflation target. This interpretation assumes that the central bank is credible when the simple mean absolute past inflation deviation from the inflation target is in the range $\langle 0, 1 \rangle$. The next credibility measure is Kia and Patron formula (Kia & Patron, 2004, p. 11) of inflation deviations from the inflation target:

$$\frac{100}{e^{0,5|\dot{y}-\pi|}}$$

The use of the exponential function shows that with increasing deviation of inflation from the inflation target the credibility of central bank decreases exponentially (faster). The interpretation of credibility here is consistent with the previous measure. The deviations from the inflation target at 1% imply the value of the formula close to 60,65 points. That is why the authors assume that the central bank is credible when the value of Kia and Patron formula is between 100 and 60 points. Figure 2 presents the possible values of Kia and Patron formula for the deviation between 0 and 10. Point A on the graph shows the bank's established credibility limit. The interpretation of the both measures is given in Table 3.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

Table 3. Interpretations of simple mean absolute deviations of past inflation from the inflation target and the Kia and Patron formula

Mean absolute deviation inflation from the inflation target during the year	Kia and Patron formula	Interpretation
<0,1>	<60;100>	Credibility
>1	60<	Lack of credibility

Source: own work.

Accuracy of the forecasts is also based on two measures whose values and ideology are consistent with the previously chosen coefficients of credibility of central bank. The first measure is the absolute deviation of past inflation forecast from the inflation target: $|\hat{y} - \pi|$, where \hat{y} is the inflation forecast. As the next step, the Forecast Absolute Error is calculated as follows $|\hat{y} - \dot{y}|$. The accurate inflation forecasts should be characterized by values smaller than 1 for both measures, which is described in Table 4.

Table 4. Interpretations of MAE and mean absolute deviation of past inflation forecast from the inflation target

MAE	Mean absolute deviation of the past inflation forecast from the inflation target	Interpretation
<0,1>	<0,1>	Accuracy
>1	>1	Lack of accuracy
>1	<0,1>	
<0,1>	>1	

Source: own work.

Besides the quantitative part of the research, qualitative analysis on the actual decision-making procedure of the CNB Board is made. Consistency of the Bank Board in IFT implementation can be a strong explanatory factor of the interdependences between the forecast and the inflation expectations. Analysis of the IFT implementation covers 4 factors (Szyszko, 2011, pp.22-23):

- formal declaration on the importance of inflation forecasts,
- consistency of the decision of the Monetary Policy Committee (MPC) with the inflation forecast result,
- decision timing,
- decision justification.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

These factors show whether the forecasts of inflation or policy path constitute an important premise in decision-making of the CNB. If they do, the possibility of shaping expectations via inflation forecasts and policy path is enhanced.

Consistency of the decision of the Monetary Policy Committee with the inflation forecast result means that its decision was in line with forecasts message. This can be analyzed in two ways consistent with the way of coding inflation forecast message. The first way refers to the central path for inflation. The rule of thumb says here that when the central path in the monetary policy horizon is above the target, the interest rates are to be raised. When the projected inflation in the monetary policy horizon is below the target – the rates should be lowered. When the forecast inflation is within the fluctuation band of the target, the MPC reaction (change of the interest rates or leaving them unchanged) is consistent with the IFT implementation. The central path of inflation at the targeted level means that the rates should be unchanged.

The second way refers to the interest rate path. Here the MPC decision is consistent with the forecast when the rates are changed according to the policy path suggestion. In the case of the Czech National Bank it is more suitable to follow this way of analyzing the Bank Board decisions, as the Bank is producing unconditional forecast with endogenous policy path.

Decision timing shows whether the central bank perceives the forecast as the best information on the future state of the economy. If it does, it makes decisions consistent with the forecast message just after the forecast is made.

Decision justification shows the main rationale behind the decision on interest rates. The central bank sends the message on the importance of forecasts to the public if it refers to the forecast message in the justification.

The last part of the research focuses on interdependences of inflation forecasts and inflation expectations of consumers. The theory assumes that inflation should be an important factor in the formation of expectations. The research is limited to the correlation of both variables and it does not refer to the cause and effect relation. The research covers 46 forecasts (July 2002-2013). The way of coding the data on inflation forecasts and policy path is described in Table 5.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

Table 5. Inflation forecast and policy path

Forecast of:	Options:	Timing
Central path of inflation	<ul style="list-style-type: none"> - the central path is below the lower boundary of fluctuation band, - the central path t is below the inflation target but within the fluctuation band; - it is at the inflation target level; - it is above the inflation target but within the fluctuation band; - the central path is above the upper boundary of fluctuation band 	Beginning of the monetary transmission horizon
Interest rates path	<ul style="list-style-type: none"> - the rates are to be lowered; - the rates are to stay unchanged; - the rates are to be raised. 	First step – just after producing forecast

Source: own work.

The inflation forecast here means not only the central projected path of inflation but the whole policy path as well. This is consistent with the Czech forecasting system. The forecast itself is unconditional – policy path is endogenous. This means that the central path of inflation should be on the inflation targeted level within the monetary policy horizon if the interest rates are changed according to the path. In reality this condition is not fulfilled, as the model does not capture future shocks and the rates are not changed in the way suggested by the path in next steps (they are actualized with the next forecast). This is why both outcomes of the model – central path of inflation and interest rates path – are confronted with inflation expectations of consumers.

The data on inflation forecast are encoded because of two reasons. First of all, consumers inflation expectations are considered. Consumers are not specialists. They do not read the forecasts on their own. They do not understand sophisticated information on inflation forecasts. It is enough to say that qualitative surveys on expectations were abandoned by the central banks, as the households awareness of economic situation was poor and the results of surveys were not reliable. The second reason for encoding the data is connected with the way how the forecast is revealed. No detailed information on levels was given at the beginning of the research period. Forecast and the policy path were presented in the Inflation Report in a descriptive way¹.

As the forecast is produced quarterly and the expectations are examined monthly, the research assumes that one forecast message may influence the expectations formation 3 times. The lags are also assumed: the forecast

¹ For central path of inflation the standard correlation measure is also calculated.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

may influence expectations in the month of its disclosure as well as during the following months.

Consumers' expectations of households are not directly observed. They are examined on the basis of regular qualitative surveys. Consumers answer the question on their inflation perception and expectations. Inflation perception refers to the past inflation and is not the subject of this research.

The question for inflation expectations is: By comparison with the past 12 months, how do you expect that consumer prices will develop in the next 12 months? And the answers to choose from: They will...increase more rapidly, increase at the same rate, increase at a slower rate, stay about the same, fall, don't know (The Joint Harmonized..., 2007, p. 51). Then the answers can be used in two ways. First of all, the balance of answers is calculated. The balance of answers does not directly measure the inflation expectations, thus it cannot be interpreted in a straightforward way. For example, when it is positive it means that the number of respondents who expected prices to increase more rapidly over the next 12 months than in the past exceeded the number of those who expected prices to remain the same or increase more slowly than in the past. (The Joint Harmonized..., 2007, p. 18).

The answers to the surveys' question on expected inflation are also the basis for quantifying inflation expectations using the adjusted Carlson–Parkin method. It assumes that if the number of respondents is sufficiently large, the expected rate of price change is normally distributed. The quantification of qualitative responses makes use of the fact that, in replying to the survey question regarding inflation expectations, respondents compare their predictions with the rate of price change as perceived when the survey is carried out (Łyziak, 2003, pp. 11-13). The latest inflation figure stays here for inflation perception.

Survey data on expected inflation are derived from the *Business and Consumers Surveys* – The European Commission survey on business and household situation. Surveys are held monthly. The Czech Republic has been covered from 1995.

The interdependences between inflation forecast (interest rate path) and expectations are calculated here. Non-parametric correlation measures are used. This is imposed by the range of data availability. The Pearson's correlation of the central path of inflation and the expectations is also tested. However, due to limited consumers' perception of economic data, coded results are more important.

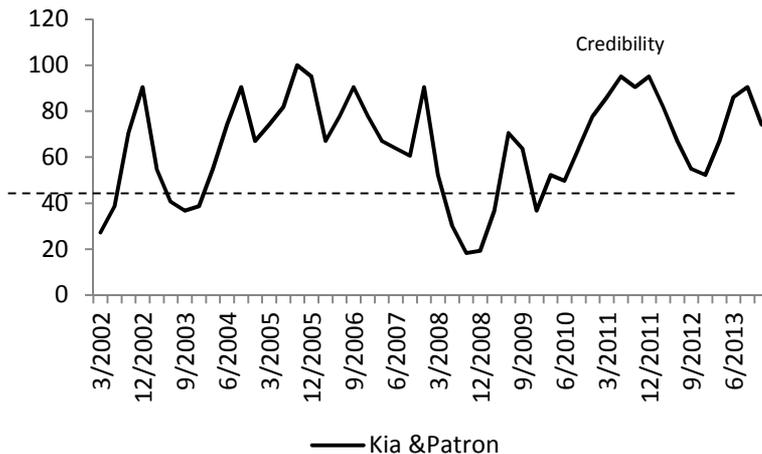

Results of the empirical research

At the first stage of the research the authors analyzed credibility of the CNB in the years 2002-2013. The study was conducted on monthly data. The formation of the values for CNB of Kia and Patron formula are presented by Figure 3.

According to results, the lack of credibility occurred temporarily in five periods: in mid 2002, in the year 2003 and in the first two months of 2004, in mid 2010, at the end of 2002. In other periods CNB can be described as credible. The mean value of Kia and Patron formula is 65,46 points.

The analysis of past inflation deviations from the inflation target, due to similar construction, gave the same results, which allowed the authors to confirm the thesis that in the years 2002-2013 CNB was credible. The summary of this step of the research is presented in Table 6.

Mean absolute deviation inflation from the inflation target	Mean value of Kia and Patron formula	Interpretation
0,98	65,46	Credibility

Source: own calculations based on ARAD database.

As the CNB during the research period was credible, the information produced by the bank could be the argument in expectations shaping of consumers.

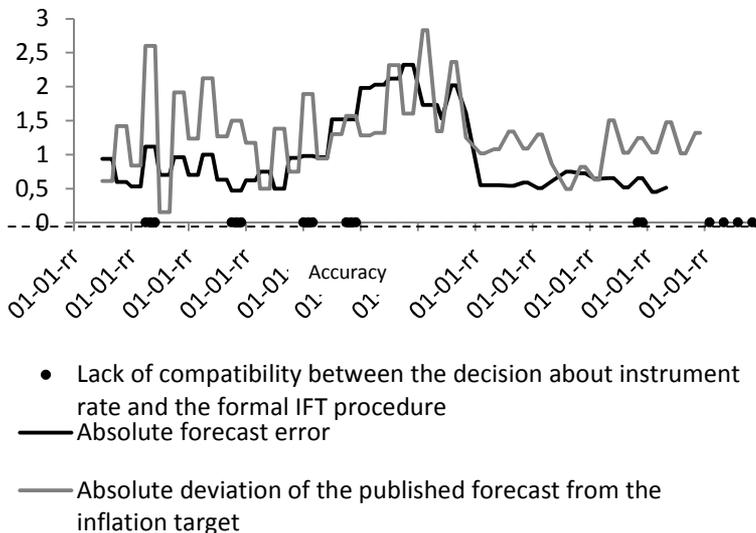

The next step of the research focuses on the forecasts accuracy. According to the idea of optimal policy, the inflation forecast is consistent with the instrument-rate forecast and at the end of the horizon it should be equal to the inflation target. That is why it is important to check how to evaluate the inflation forecasts in relation to the inflation target. At this step of the research the authors analyzed the mean absolute past inflation forecasts deviation from the inflation target in CNB from July 2002 to May 2012 (the period of the study was chosen due to available data). The research was conducted on quarterly data. The value of the mean absolute deviations of past inflation forecasts from the inflation target is 1,31%. The next part of the analysis of inflation forecasts was calculation the absolute forecasts errors. The value of the mean absolute forecasts error (MAE) of the inflation forecasts is 1,07 %. The results show that inflation forecasts published by CNB in the chosen period were inaccurate. The summary of this step of the research is presented in Table 7.

Table 7. Interpretations of MAE and mean absolute deviation of past inflation forecast from the inflation target in CNB

Figure 4. Accuracy of the inflation forecasts and their compatibility with IFT procedure in CNB

Source: own calculations based on ARAD database, data and information from *Inflation Reports and Statements* of CNB Board published by CNB in years 2002-2013 and data obtained from bank employees.

The results of the first and the second part of the research create a background for the analysis of interdependences of expectations and forecasts results. The CNB in the period covered by the examination was credible, which is the first step to properly anchored the inflation expectations. Unfortunately, the results also show that the CNB inflation forecasts in the same period were not accurate and were not a good forecast in the sense of predicting future inflation. On the other hand, the value of the mean deviation from the inflation target (which is 1,07 %) implies that the forecasts did not deviate strongly from the inflation target. That is why the forecasts can still be seen as a useful tool according to IFT ideology.

The third step of the research focuses on IFT implementation in the CNB. The CNB shows strong commitment to IFT implementation. It starts on the declarations level – the forecast is claimed to be of greatest relevance in decision-making (which is declared at the website of the Bank and in its strategic documents). This declaration meets the practice of the Bank Board as it changes rates accordingly to the message of forecast and does it when the forecast has just been produced. In the examined period (114 meetings of the Bank Board, 46 forecasts discussed) only 9 times the Board ignored the message of forecasts (in terms of interest path). This cases are called decision's deviations. The details of the explanations are given below. They are divided into two groups (presented in Table 8). The first one covers deviations from 2003 to 2011. Their rationale is shock or wait and see attitude of the CNB. The second group covers 2013. The reason for not following the message was technical – the Bank had been already operating at the nominal zero rate. The Board announced the possibility of intervention on the FX market to weaken the Czech koruna. The message of the forecast was ignored because it was not possible to follow it. The methodology of analysis is clear and classifies these cases as decisions' deviations. Except those special situations, the CNB followed the interest path consistent with its macroeconomic forecast. Even in the most turbulent period of the end of 2008 and 2009, the Board's decisions were in line with the forecast path of interest rates. The precondition of using inflation forecasts as the tool that supports expectations shaping is thus fulfilled.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

Figure 4 that presents the measures of the forecast accuracy also contains the information on the compatibility of the Bank Board decisions with IFT. It shows that inflation forecasts played a role of intermediate target in CNB, even though most of them were inaccurate.

The results of the research on interdependences between expectations and forecasts results are presented in Table 9. They prove the existence of statistically important (for $p=0,05$) interdependences of inflation forecast and expectations. Their strength is moderate and it rises with the lengthening of the lag. For the inflation forecast the results of non-parametric statistics are also confronted with the standard correlation measure (for quantified inflation forecast) that confirms the results for the coded data

The results concerning the central path (here referred to as CP – central path of inflation) are not surprising. If the forecasts showed that inflation would exceed the goal, the expectations rose.

However, the results on interest path (PP – policy path) are counterintuitive. They show that when the rise of the rates is consistent with the macroeconomic forecast, the expectations of consumers rise as well. Transmission mechanism based on the modern theory draws a negative correlation of interests rates and expectations. The results obtained for the CNB show that the forecast itself guides expectations rather than policy path.

Table 9. Interdependences of forecasts and expectations 2002-2013

Variables	Lag	Spearman	Gamma	Kendall	Pearson

Source: own calculations based on data and information from *Inflation Reports* published by CNB in years 2002-2013.

The results of examination of the interdependences and the CNB's decision-making procedure may not be interpreted unambiguously. First of all, a positive correlation of policy path and expectations of consumers is surprising. Secondly, the strength of interdependences is moderate. The forecast is not the only one factor influencing expectations. A possible explana-

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

tion of moderate strength (instead of strong relationship) is inaccuracy of the forecasts. Thirdly, the existence of positive relationships between inflation forecast and expectations proves that consumers do not really perceive that the central bank is effective in its actions. In the case of perfect credibility, inflation expectations are on the target level.

In the years 2002-2013 the CNB could be characterized as a credible central bank, however its credibility was not perfect. The CNB forecasts were inaccurate. It is sure that this non perfect credibility and inaccuracy of the forecast hves an impact on interdependences. It must also be remembered that CNB is implementing a flexible type of IFT. That is why accomplishment of other target variables (like output gap) could be carried out at the expense of the accuracy of inflation forecasts.

It should be mentioned that the research was held for consumers – a less educated group in the economy (as compared with specialists and companies). This is why the unambiguous results are not surprising.

Conclusions

In the model situation, the perfectly credible central bank publishes accurate forecasts which anchor the economic agents' inflation expectations on the target level of inflation. The CNB is not perfectly credible and it publishes inaccurate forecasts – according to methodology of the research. However, those forecasts play the role of intermediate target of monetary policy. They are also correlated with inflation expectations of consumers. The results of the research are far away from the model situation but in practice they are not bad. Anchoring inflation expectations is the main function of inflation forecasts made by central banks implementing inflation targeting strategy. So, predicting the future value of inflation is not the most important. From this point of view, inflation forecasts of the CNB fulfill the main goal of revealing them – they are correlated with inflation expectations. The research confirmed the main body of the hypothesis that inflation forecasts published by CNB in the years 2002-2013 were correlated with inflation expectations of households, regardless of the fact that the hypothesis of the forecast accuracy is rejected. The problem is connected with the forecasting system (that produces inaccurate forecasts), while the other results are consistent: credible central bank that implements IFT may affect expectations via forecasts.

There are several directions of further research. The most obvious is expanding the scope of the research on the other central banks. Such a com-

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

parative analysis can be enriched with the countries of the longest experience in inflation forecast targeting. Having the panel of countries that implement IFT and their forecast-expectations interdependences, further questions on the results can be answered:

- Does the strength of correlation depend on consistency in IFT implementation?,
- Does the strength of correlation depend on the forecasts accuracy?
- Do the interdependences depend on the credibility of the central bank and its effectiveness?
- Does the transparency of the central bank influence the relationship of the expectations and the forecast results?

The field for methodological improvement also exists in this kind of research: the data on forecast results may be encoded in a different way. Finally, for that kind of data, the probit model showing not only interdependences but cause-effect relation could be developed.

In the conducted research the authors have calculated the credibility of central bank based on past inflation deviations from inflation target, analyse inflation forecasts by absolute forecasts errors and past inflation forecasts deviation from the inflation target and also interdependences between forecasts and inflation expectations.

Elements of the study were selected so that their ideology was related and due to their simplicity. The obtained values of used measures correspond with each other. These components, along with a qualitative assessment of the use of forecasts, form the implementation of the idea of IFT in the CNB. The results are a contribution to the creation of complex index specifying the degree of implementation of the IFT strategy in central banks.

Regardless of the future expansion of the research, the results obtained here deliver valuable information on the function of forecasts.

**“Fettered” and “Unfettered” Capitalism in
J.A. Schumpeter’s Concept of Tax State
and Economic Development**

JEL Classification: *A13; B15; K20; P7; P20*

Keywords: *Schumpeter; capitalism; Tax State; economic development*

Abstract: Economic development and transformation processes, have become much more intense in economic reality in the last years than they have ever been before. At this time has raised a lot of questions about the causes of the actual Global Crisis, future crises, the factors affecting the modern economy, about the essence of contemporary capitalism, demographic problems and overgrown bureaucracy. The most spectacular threat to capitalism, (based on private entrepreneurship) according to Schumpeter, stems from the high, growing and progressive taxation. Schumpeter saw clearly that the financing of public goods and services (requiring taxes, maybe even relatively high) is something other than a clerical control of the economic system that violates the natural economic mechanism. Moreover Schumpeter says explicitly, that entrepreneur does not have to be one person, he even states that the country (state) itself, or its agenda, can act as an entrepreneur. Therefore can be concluded that we may have to deal with “Tax State” which is typical for “fettered capitalism” and with “entrepreneurial state” which is typical for “unfettered capitalism”. The main goal of this paper is to present two different approaches to economic development concept: Schumpeter’s “fettered” and “unfettered” capitalism in the context of “Tax State” and interventionism.

Introduction

Economic development and transformation processes, have become much more intense in economic reality in the last years than they have ever been before. In the United States during and after Global Financial Crises (2007-2009) over \$16 trillion of USD was allocated to corporations and banks internationally for “financial assistance”. Recently European Central Bank (EBC) decided that it will spend 1,2 trillion of EUR to stimulate European economy. For over a year EBC will be spending 60 billion of EUR monthly because of the Euro Debt Crisis. Having regard to the deflation in Japanese and Swiss economy this appears to be not very optimistic view of the developed economies. On the other side we have BRICS countries (Brazil, Russia, India, China and South Korea) where economic processes begin to create the opportunity for sustainable development.

At this time has raised a lot of questions about boundary between state intervention and the free market capitalist economy, about the causes of the actual Global Crisis, future crises, the factors affecting the modern economy, about the essence of contemporary capitalism (probably with too much fiscalism), demographic problems of Europe and overgrown bureaucracy. Some of the answers could be found in works of Joseph Alois Schumpeter – economist who could predicted in his theories contemporary changes in economies.

Schumpeter writing one of his most recognizable book - *Capitalism, Socialism and Democracy*, claimed that by “extrapolating observable tendencies”, capitalism would eventually produce an “atmosphere of almost universal hostility to its own social order” (Schumpeter, 1943, p. 143). In this work Schumpeter presented the “transition from capitalism to socialism, where the entrepreneurial function as well as the entrepreneurial class would disappear. The large corporation, by taking over the entrepreneurial function, not only makes the entrepreneur obsolete, but also undermines the sociological and ideological functions of capitalist society”. Schumpeter also states that “there is inherent in the capitalist system a tendency towards self-destruction...[it] not only destroys its own institutional framework but it also creates the conditions for another” (Schumpeter, 1943, p. 162).

Moreover, in reference to the ills of modern economies Schumpeter’s early original article on the “*Crisis of the Tax State*” (1918) seems to be very timely. This is confirmed by the work of authors such as: Backhaus (1989, 2003), Chaloupek (2000), Hanusch (1988), Heertje (1981) or even OECD. The reason why Schumpeter wrote “*Crisis of the Tax State*” was

the answer to Rudolf Goldscheid's article on "Staatssozialismus oder Staatskapitalismus" (1917). However Schumpeter's paper must be treated as a reliable element of Schumpeter's concept of politico-economic analysis.

This paper proceeds as follows. First author presents Schumpeter's concept of a "fettered" capitalism. Secondly was presented concept of "unfettered" capitalism and the conclusions. In this paper author used such research methods as: a comparative analysis, analogy and deductive inference. The main goal of this paper is to present two different approaches to economic development theory: Schumpeter's "fettered" and "unfettered" capitalism in the context of "Tax State" and interventionism.

"Fettered" capitalism

Schumpeter in his historical analysis of "fallen capitalism" pointed out so-called "institutional flaws" as a threats to western economies. Pure model of capitalism (as Schumpeter called it "vital and intact or unfettered" capitalism) increasingly become more and more "fettered" capitalism. According to Schumpeter's observation, (in the twentieth century) became apparent gradual process of applying to the dynamism of capitalist development further "embarrassing shackles" in the form of various regulations. Reason for this situation was the steady overgrowth of the public sector. This phenomenon was accompanied by the constantly increasing burden of taxes.

In his study on "The Crisis of the Tax State" Schumpeter describes the transformation of the feudal power system to the capitalist system consisting of two sectors: the "free economy" and the "Tax State". As the expenditures of the sovereign were increased by wars, administration and consumption at the court, the sovereign had to transfer rights and privileges to the guilds and merchants. The mechanism of the Tax State thus is characterized by (Backhaus, 2003, p.342):

- longterm change of the source of revenues from the disposal on natural resources and privileges to indebtedness and subsequently to taxes,
- longterm change of the social structure,
- longterm change of the political system.

Excessive growth of the public sector causes social and general-economic costs associated with conflict, which is a struggle between the public and private sector. Struggle between the intervening state (government) and defending itself against the intervention of a private entrepre-

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

neur. At this point Schumpeter draws attention to a particular part of the costs associated with this struggle. These costs relate to legal apparatus (lawyers) functioning on one side of a huge and costly legal apparatus in the service of the bureaucracy and on the other side the army of the most eminent lawyers employed by the private sphere in order to minimize the effects of public regulation. A considerable part of the total work done by lawyers goes into the struggle of business with the state and its organs. It is immaterial whether we call this vicious obstruction of the common good or defense of the common good against vicious obstruction. But not inconsiderable is the social loss from such unproductive employment of many of the best brains. Considering how terribly rare good brains are, their shifting to other employments might be of more than infinitesimal importance (Schumpeter, 1943, p. 198).

The most spectacular threat to capitalism, (based on private entrepreneurship) stems from the high, growing and progressive taxation (Schumpeter, 1918). In his work, author shows that contemporary socio-economic system tends rapidly to a maximum tax burden on the private sphere of entrepreneurship, which leads to a weakening of economic dynamism. Schumpeter describes the transformation of the feudal power system to the capitalist system consisting of two sectors: the “free economy” (unfettered capitalism) and the Tax State (fettered capitalism).

Schumpeter's concept of the Tax State was established under the influence of Rudolph Goldscheid's *Staatssozialismus oder Staatkapitalismus* from 1917. Comparing Goldscheid's and Schumpeter's views of the state and public finance, we can conclude, that Goldscheid's concept has more dynamic character than Schumpeter's concept. Goldscheid's emphasis on the necessity of entrepreneurial initiatives carried out by the state is taken to be a realistic assumption. Schumpeter's concept instead seems to be oriented to entrepreneurial activities and innovativeness not in the state and public administration sector, but in the private sector, the “free economy” (Backhaus, 2003).

Schumpeter's approach of the Tax State applies a long-term perspective, it therefore must consider all of the drivers of the economic development as variables, and it thus has to go beyond standard economic analysis of taxes. What is needed furthermore, is the integration of new economic, political, institutional, historical and sociological aspects. Evolutionary economics and endogenic growth theory may be applied in order to analyze the long-term development of the two sectors of the economy, the “free economy” (unfettered capitalism) and the public sector. It also intensively explore the

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

correlation of both sectors. That is why, the long-term effects of both sides of the public budget – revenues and expenditures – have to be taken into account as variables of the long-term economic development (Backhaus, 1997, p. 273).

Schumpeter wrote that “the fundamental impulse that sets and keeps the capitalist engine in motion comes from the new consumers’ goods, the new methods of production or transportation, the new markets, the new forms of industrial organization that capitalist enterprise creates (...) it’s a process of industrial mutation - if I may use that biological term - that incessantly revolutionizes the economic structure *from within*, incessantly destroying the old one, incessantly creating a new one. This process of Creative Destruction is the essential fact about capitalism.” (Schumpeter, 1943, p. 83.). In “*Capitalism, Socialism, and Democracy*” (Schumpeter, 1943), Schumpeter recognized that the concept of dynamic capitalism was condemned to failure because the increased efficiency of the capitalist enterprise would lead to monopolistic structures and it will cause loss of the idea of entrepreneurship. This monopolistic structures nowadays may come from possible use of intellectual property protection in the form of a patent. But Schumpeter actually argued that innovation should lead to temporary monopoly, not that monopoly causes innovation in enterprise. This monopoly cannot come from intellectual property protection but from the fact that entrepreneur is an innovator whose competitive position comes from innovation implementation in economy.

This concept is also actual in nowadays mega-banks problem. The basic problems with the modern banks are mainly related with the level of concentration in the banking sector, the bonuses of the management (which are the derivative of bank’s motivational systems) but most of all are related with phenomenon that the banking sector is pursuing goals, that are harmful to the long-term economic profitability. According to Schumpeter banks should stimulate innovations implemented by entrepreneurs in the economy. Unfortunately the bankers nowadays seemed to have other priorities than those implied by their function in the economic system (Śledzik, 2014).

In one of his last works Schumpeter further highlights that it is high taxes, which are the expression and the result of decomposition of Western capitalism, are the most important premise of the transformation of capitalism into socialism (Schumpeter, 1949, p. 374). Schumpeter defines “true socialism” as a organization, which ceded control (ownership) of the means of production and production program and the right to request the income derived from the use of the means of production other than labor, to a cen-

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

tral authority, which may be (but not necessarily) the government or parliament. Schumpeter even then pointed out the problem, that today in the era regulations introduced by the European Union, International Monetary Fund and the World Trade Organization, is essential. He saw clearly that the financing of public goods and services (requiring taxes, maybe even relatively high) is something other than a clerical control of the economic system that violates the natural economic mechanism. These statements are highly relevant today, when we witnessed boom and bust of the Credit Crunch recession of 2007-2009, and Europe's sovereign debt crises.

“Unfettered” capitalism

According to any standard dictionary if you describe something as “unfettered”, you mean that it is not controlled or limited by anyone or anything. So what Schumpeter had in mind when writing “unfettered capitalism”? According to Schumpeter whereas a stationary feudal economy would still be a feudal economy, and a stationary socialist economy would still be a socialist economy, stationary capitalism is a contradiction in terms (Schumpeter 1943, p. 179). He also writes that: “... capitalist reality is first and last a process of change” (Schumpeter 1942, p. 77). The change is the essence. And this “change” is crucial for the Schumpeter’s concept of “unfettered capitalism”. In the economy “change” should come from entrepreneurship who is an innovator, and should not come from states interventionism, which causes excessive taxes and bureaucracy inhibiting innovation.

Let me note on this particular point that in the late thirties, Schumpeter began to move away from his earlier theory of entrepreneurship, then ultimately at the end of the thirties he presented “new theory”, which is completely different (Swedberg, 1991). In the *Business Cycles* (1939), Schumpeter put much greater emphasis on innovation in the strict sense, than on the entrepreneurship. The „new theory“ of entrepreneurship has been outlined by Schumpeter in four articles: *The Creative Response in Economic History* (1947), *Theoretical Problems of economic Growth* (1947), *Economic Theory and Entrepreneurial History* (1949) and *The Historical Approach to the Analysis of Business Cycles* (1949) (Clemens, 2009). This new concept was less “individualistic”. Schumpeter says explicitly, that entrepreneur does not have to be one person (which is a radical departure from his earlier recognition entrepreneur as an outstanding individualist). Schumpeter even states that the country (state) itself, or its agenda, can act

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

as an entrepreneur. This is crucial for achieving the purpose of this paper. Therefore can be concluded that we may have to deal with “Tax State” which is typical for “fettered capitalism” and with “entrepreneurial state” which is typical for “unfettered capitalism”.

Concerning the problem of stability of the state, Schumpeter indeed pointed out that the modern state had come to existence out of a situation of fiscal need, and that a tendency towards instability in terms of a financial crisis is directly inherent to the capitalist state. Schumpeter intended to argue that a steady economic development of the two sectors may be possible, but that distinct conditions would have to be fulfilled. These conditions may concern the institutional framework, but also the organization of the enterprises and economic activities. Both sectors, the public and the private sector, must be coordinated as being complementary to each other (Backhaus, 2003, p.345). Schumpeter has always insisted that the state (government) is naturally accompanied by capitalism and the market economy. Furthermore, it is necessary for its operation and for the stability of society and its rules. Capitalist economy cannot function without the public sphere, financed by taxation. Tax system is essential to the reproduction of capital as much as money and credit (Vecchi, 1995, p.83-84).

In ‘Schumpeterian capitalism’ creation, ownership and distribution of wealth were in part left up to the state (government). However, in an entrepreneurial society it is individual initiative that plays an important role in propelling the system forward. Entrepreneurial leadership is the mechanism by which new combinations are created, new markets are opened up and new technologies are commercialized that are the basis for prosperity. In an entrepreneurial society, entrepreneurship plays an essential role in the process of wealth creation and philanthropy plays a crucial role in the reconstitution of wealth (Acs, 2007, p.103). It is not the innovations that have created capitalism, but capitalism that has created the innovations needed for its existence. One could gain the opposite impression only from the fact that we know only of an economy replete with development, and here, everything takes place so fast and immediately, that we cannot always distinguish between cause and effect (Backhaus, 2003, p.71).

Furthermore, modern capitalism was perceived as an economic system that had experienced an early phase of expansion, followed by a phase of dynamic high capitalism and then transformed into a phase of an increasingly bureaucratic late capitalism, heralding the possible advent of a non-capitalist transformation (Backhaus, 2003, p.123). ”The essential point to grasp is that in dealing with capitalism we are dealing with an evolutionary

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

process. (...) Capitalism, then, is by nature a form or method of economic change and not only never is but never can be stationary. (...) The fundamental impulse that sets and keeps the capitalist engine in motion comes from the new consumer's goods, the new methods of production or transportation, the new markets, the new forms of industrial organization that capitalist enterprise creates. (...) Economic evolution was said to manifest itself in structural changes: the same process of industrial mutations – (...) – that instantly revolutionizes the economic structure *from within*, incessantly destroying the old one, incessantly creating a new one. This process of Creative Destruction is the essential fact about capitalism" (Schumpeter 1942, p. 82-83). The future course of capitalism should remain basically undetermined, thus history would persist as an open-ended evolutionary process. It's impact cannot be predicted as it creates novel situations which would not have been possible in its absence (Schumpeter 1947, p. 150).

Another interesting issue in the Schumpeterian capitalism is the role of bank and credit in the implementation of innovation in the "capitalist free economy". As Schumpeter says: "capitalism is that form of private property in which the innovations are carried out by means of borrowing money, which in general implies credit creation" (Schumpeter, 1939, p.223) and credit is "nothing but a means of diverting the factors of production to new uses, or of dictating a new direction to production" (Schumpeter, 1911, p.116). The banker, therefore, is not so much mainly a broker in the commodity *purchasing power* as a producer of this commodity (...) he has either replaced private capitalists or become their agent. The banker has himself become the capitalist *par excellence*. He stands between those who wish to form new combinations and the possessors of productive means. He is essentially a product of development, though only when no authority directs the social process. He makes possible the carrying out of new combinations, authorizes people, in the name of society as it were, to form them. He is the "ephor" of the exchange economy (Schumpeter, 1911, p.74). Enterprises that wish to innovate should not finance innovation with financial investment achieved from the previous production. (Schumpeter, 1934). The problem is that the modern "ephor" is not always interested in implantation of innovation in the economy. "Moreover, the fact that *seven* of the most famous banks in the world have admitted massive breaches of US sanctions designed to inhibit Iran from developing an atomic bomb, acts of treason against world security, confirms that the search for corporate banking profits is now without constraint" (Kingston, 2014).

Conclusions

It is extremely difficult to draw the line between “fettered” and “unfettered” Capitalism. But in modern economies which are knowledge based, globalization based, internet based, innovation and technology based and tax, bureaucracy, state interventions based at the same time – the task is not as problematic any more. Tax State analysis should be based on a long-term dynamic view and should be focused on the study of the long-term development of the economic system. Schumpeter says that even states, the country (state) itself, or its agenda, can act as an entrepreneur. This is crucial for achieving the purpose of this paper. Therefore can be concluded that we may have to deal with “Tax State” which is typical for “fettered capitalism” and with “entrepreneurial state” which is typical for “unfettered capitalism”.

What is important, in the context of nowadays US and EU economic problems, is that according to Schumpeter the crisis of the Tax State is not only understood as a financial crisis but – even more important – as a legal and political crisis. Is it not true, that in “unfettered” capitalism banks which has caused financial global crises should not bear the consequences. They should fail and should be replaced (maybe in the process of creative destruction) by new banks with money financing Schumpeterian innovations and development instead of speculation. In this connection fact, that this “financial creative destruction” was impossible to occur in US and in the EU economies, only reinforces the belief that capitalism in these economies is beginning “fettered”. This may proved that Schumpeter was right in his forecast that capitalism would sooner or later be replaced by socialism.

Decomposing the Net Efficiency of Active Labor Market Programs

JEL Classification: *C21; C25; J68*

Keywords: *Oaxaca-Blinder decomposition*

Abstract: Each state intervention in the labor market must be evaluated at the end in terms of efficiency. It is especially important during periods when the resources allocated for this purpose are limited. The most common the gross efficiency is estimated. The gross efficiency is the percentage of people who found employment after the program. Gross efficiency indicators contains a number of apparent effects that distort the effect of intervention. Therefore one estimates net efficiency indicators, which reflects the actual effect of state intervention in the labor market. The aim of this paper is to estimate the net efficiency indicator of active labor market programs using the Oaxaca-Blinder decomposition. Analysis will be carried out on the base of data sets of unemployed participating and not participating in active labor market programs.

Introduction

Labor Market Policy is aimed at solving structural problems of labor market and improving the efficiency of its functioning. Labor Market Policy is based on specialized instruments that adjust the structure of supply of work to the structure of demand for work. It has microeconomic character. Labor Market Policy is a state intervention in the labor market in case of imbalance on the labor market and it doesn't create new places of work. In

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

the process of achieving the objectives of the labor market policy one uses many instruments, which could be divided into active and passive ones. Active Labor Market Programs are in general directed to prepare the unemployed to reenter into the process of work and should be used especially to those with highest risk of unemployment and living in the regions with most difficult labor market situation. The aims of active labor market policy are:

- elicitation of unemployed,
- decreasing the structural mismatching in the labor market,
- increasing the productivity of labor force and verification the willingness of the unemployed to work.

The group of active instruments is composed of:

- career counseling and placement services,
- job search assistance,
- trainings,
- rotation and job sharing,
- subsidised employment.

The group of passive instruments is composed of employment benefits and early retirement.

Each state intervention in the labor market must be evaluated at the end in terms of efficiency. Efficiency indicators are calculated in general for active labor market programs. In most cases gross efficiency indicators are calculated and are interpreted as a percent of unemployed who moved to employment following the end of the active labor market program. Gross efficiency indicators contain several apparent (external) effects for example deadweight loss which is defined as the hirings from the target group that would have occurred also in the absence of the programme (Calmfors, 1994). External effects distort the real causal impact of active labor market program. This is the substantial reason explaining why one should estimate net efficiency indicators of the programs.

Several methods of estimation the net efficiency indicators are proposed. One of the most popular is the Propensity Score Matching method, which is based on counterfactual states theory. The main idea of this method is that for each participant it matches one or more non-participants with equal or similar probability of participating in the programme (Heckmann, Ichimura, Todd, 1997).

When we obtain a control group we can estimate casual state intervention effect on the labor market. Net casual effect is estimated with the formula (Caliendo, 2006):

$$\Delta^{MAT} = \frac{1}{N_1} \sum_{i \in I_1} \left[Y_i^1 - \sum_{j \in I_0} w_{ij} Y_j^0 \right],$$

where:

Δ^{MAT} is the net effect of the state intervention,

N_1 is the number of participants of the program,

I_1 is the subset of participants of the intervention,

I_0 is the subset of nonparticipants of the intervention,

w_{ij} is a weight for j -th unemployed in a control group, which is used to estimation a counterfactual effect for i -th participant.

For each participant a sum of weights w_{ij} of similar nonparticipants must be equal to 1.

An alternative for matching methods are model-based methods. One of them is Oaxaca-Blinder decomposition, which is based on econometric models.

The aim of this paper is to estimate the net efficiency indicator of active labor market programs using the Oaxaca-Blinder decomposition. The substantial part of analysis is the estimation of the impact of each characteristic of the unemployed on the net efficiency indicator.

Methodology of the research

To estimate net efficiency indicators we will use the method called Oaxaca-Blinder decomposition and its modification. For a linear regression, the standard Oaxaca-Blinder decomposition is the difference between two groups in the average value of the dependent variable Y can be written as (Oaxaca, 1973; Blinder, 1973):

$$\bar{Y}_A - \bar{Y}_B = [\bar{X}_A \beta_A - \bar{X}_B \beta_A] + [\bar{X}_B \beta_A - \bar{X}_B \beta_B],$$

where:

\bar{Y}_A is the mean outcome for the group of participants of active labor market programs,

\bar{Y}_B is the mean outcome for the group of nonparticipants of active labor market programs,

β_A is the vector of coefficients in the model of outcome for the group of participants of active labor market programs,

β_B is the vector of coefficients in the model of outcome for the group of nonparticipants of active labor market programs,

\bar{X}_A is the vector of mean values of characteristics of the group of participants of labor market programs,

\bar{X}_B is the vector of mean values of characteristics of the group of nonparticipants of labor market programs.

The decomposition for a nonlinear case $Y = F(X\hat{\beta})$ can be shown as:

$$\bar{Y}_A - \bar{Y}_B = [\overline{F(X_A\beta_A)} - \overline{F(X_B\beta_A)}] + [\overline{F(X_B\beta_A)} - \overline{F(X_B\beta_B)}],$$

where:

$\overline{F(\cdot)}$ represents the mean value of the theoretical values from nonlinear or linear model.

The first part of the decomposition $[\overline{F(X_A\beta_A)} - \overline{F(X_B\beta_A)}]$ represents the differences in characteristics and the second one $[\overline{F(X_B\beta_A)} - \overline{F(X_B\beta_B)}]$ denotes the differences in coefficients.

The most important thing is to find the contribution of each variable to the total difference. If the function F is linear, obtaining detailed decomposition equation is trivial. But in case of nonlinear F function, the key problem is how to estimate the contribution of particular variables to the characteristics and coefficient effects. The solution of this problem is to use two types of approximation. First type of approximation evaluates the value of the function by using mean characteristics. The second type of approximation is based on first order Taylor expansion which linearizes the characteristics and coefficients effects around $\bar{X}_A\beta_A$ and $\bar{X}_B\beta_B$, respectively (Yun, 2003).

The decomposition with weights takes the form (Yun, 2003):

$$\begin{aligned} \bar{Y}_A - \bar{Y}_B = & \sum_{i=1}^k W_{\Delta X}^i [\overline{F(X_A\beta_A)} - \overline{F(X_B\beta_A)}] \\ & + \sum_{i=1}^k W_{\Delta \beta}^i [\overline{F(X_B\beta_A)} - \overline{F(X_B\beta_B)}] \end{aligned}$$

where:

$W_{\Delta X}^i = \frac{(\bar{X}_A^i - \bar{X}_B^i)\beta_A^i}{(\bar{X}_A - \bar{X}_B)\beta_A}$ weights concerning characteristics of unemployed,

$W_{\Delta\beta}^i = \frac{\bar{X}_B^i(\beta_A^i - \beta_B^i)}{\bar{X}_B(\beta_A - \beta_B)}$ weights concerning coefficients,

$$\sum_{i=1}^k W_{\Delta X}^i = 1,$$

$$\sum_{i=1}^k W_{\Delta\beta}^i = 1.$$

Above decomposition may be considered as a general decomposition accounting for differences in the first moment. The only requirement is that the function F must be once differentiable. In many practical applications as a F function, a probit and logit model is used (Even, Macpherson, 1990; Nielsen, 1998; Yun, 2000). A described methodology of nonlinear decomposition technique will let us to estimate the net efficiency indicators for active labor market programs and identify causes of differences in moving to employment between groups of unemployed participants (group A) and non-participants (group B) of active labor market programs.

Data used for the analysis

Data used to conduct the analysis contain information about the unemployed in Toruń City. Analysis was conducted for two periods of time: year 2009 and year 2010. Datasets contained variables describing unemployed:

- Y – binary variable taking value 1 if an unemployed person turned employed and 0 in other case,
- SEX – binary variable taking value 1 for men and 0 for women,
- ENG – binary variable taking value 1 for unemployed with fluent or medium knowledge of English,
- UN_BEN – binary variable taking value 1 if an unemployed person received an unemployment benefit,
- $CHILD0$ – binary variable taking value 1 if an unemployed person had no children,
- $CHILD1$ – binary variable taking value 1 if an unemployed person had one child,
- $CHILD2$ – binary variable taking value 1 if an unemployed person had two or more children (this is a base variable for the group of variables describing number of children),
- $EDUC0$ – binary variable taking value 1 for unemployed with incomplete primary or primary or lower secondary education,

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

- *EDUC1* – binary variable taking value 1 for unemployed with basic vocational education,
- *EDUC2* – binary variable taking value 1 for unemployed with general secondary education (this is a base variable for the group of variables describing education),
- *EDUC3* – binary variable taking value 1 for unemployed with post-secondary and vocational secondary education,
- *EDUC4* – binary variable taking value 1 for unemployed with tertiary education,
- *OCCUP0* – binary variable taking value 1 if an unemployed person had no occupation,
- *OCCUP1_2* – binary variable taking value 1 if an unemployed person had occupation that belongs to the first (Managers) or second (Professionals) large group of occupations from the *Classification of occupations and specialities* (this is a base variable for the group of variables describing occupation),
- *OCCUP3* – binary variable taking value 1 if an unemployed person had occupation belonging to the third large group of occupations – Technicians and associate professionals,
- *OCCUP4* – binary variable taking value 1 if an unemployed person had occupation belonging to the fourth large group of occupations – Clerical support workers,
- *OCCUP5* – binary variable taking value 1 if an unemployed person had occupation belonging to the fifth large group of occupations – Service and sales workers,
- *OCCUP6* – binary variable taking value 1 if an unemployed person had occupation belonging to the sixth large group of occupations – Skilled agricultural, forestry and fishery workers,
- *OCCUP7* – binary variable taking value 1 if an unemployed person had occupation belonging to the seventh large group of occupations – Craft and related trade workers,
- *OCCUP8* – binary variable taking value 1 if an unemployed person had occupation belonging to the eighth large group of occupations – Plant and machines operators and assemblers,
- *OCCUP9* – binary variable taking value 1 if an unemployed person had occupation belonging to the ninth large group of occupations – Elementary occupations,

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

- *MARITAL1* – binary variable taking value 1 if an unemployed person was married,
- *MARITAL2* – binary variable taking value 1 if an unemployed person was single,
- *MARITAL3* – binary variable taking value 1 if an unemployed person had other marital status (this is a base variable for the group of variables describing marital status),
- *AGE* – continuous variable describing age of the unemployed,
- *SENIORITY* – continuous variable describing seniority of the unemployed,
- *PART* – binary variable taking the value equal to 1 if an unemployed person belonged to the group of participants of active labor market programs.

A variable *PART* takes the value equal to 1 for all unemployed who took part in such active programs like: grants for starting business, trainings, intervention works, internships, public works and socially useful works.

Results of the analysis

On the base of datasets we estimated net efficiency indicators for specified active labor market programs. As a *F* function we used three types of probability model:

- linear: $P(Y = 1) = X\beta$,
- logit: $P(Y = 1) = \frac{e^{X\beta}}{1+e^{X\beta}}$,
- probit: $P(Y = 1) = \int_{-\infty}^{X\beta} \frac{1}{2\pi} e^{-\frac{t^2}{2}} dt$.

Results of the estimation of net efficiency indicators and wages describing the impact of each characteristic of unemployed to the value of indicator.

Source: own calculations.

On the base of averages one can state that in the year 2010: the share of men in both groups increased, the share of unemployed with knowledge of English in both groups increased, the share of unemployed receiving unemployment benefit in both groups decreased, the share of unemployed with no children decreased and the share of unemployed with one child in both groups increased. The share of unemployed with tertiary education decreased in both groups. The share of unemployed with incomplete primary or primary or lower secondary education decreased for the group of participants and increased for the group of nonparticipants of active labor market programs. The shares of unemployed with post-secondary and vocational and with basic vocational education increased for the group of participants and decreased for the group of nonparticipants. Due to occupation the highest increase of a share was for unemployed with occupations belonging to the fifth large group of occupations. This situation concerned participants and nonparticipants. The share of married unemployed increased in both

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

groups. The share of single unemployed decreased only for the group of participants. The average seniority increased only for the group of participants. The average age increased in both groups.

<i>NET EFFICIENCY</i>	0.2008		26.86	73.14

Source: own calculations.

Estimated net efficiency indicator calculated for the year 2009 on the base of linear regression equals to 0.2008. This value represents the real effect of participation in active labor market programs and one can state that participants more often received a job in comparison with nonparticipants. Only 26.86% of the net efficiency indicator is explained by differences in characteristics of unemployed, the rest 73.14% is an unexplained part of the indicator. The biggest positive impact of differences in characteristics on the indicator had age, lack of education or tertiary education,

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

occupation belonging to the seventh large group of occupations. The biggest negative impact of differences in characteristics on the indicator had receiving employment benefit, being married and seniority. The impact of differences in coefficients had in general negative influence on the efficiency indicator of the active labor market programs. The biggest impact had receiving unemployment benefit, possessing post-secondary or vocational secondary education, having occupation belonging to fifth or seventh large group of occupations and seniority.

<i>NET EFFICIENCY</i>	0.1834		18.19	81.81

Source: own calculations

Results received from the probit model are, like for the year 2009, similar to linear model and logit model-based. Net efficiency indicator is slightly higher than in previous cases and equals to 0.2003. Share of the explained part is higher than in case of linear model-based calculation and smaller than in logit model-based calculation and equals 18.19%. The impact of each difference in characteristic and coefficients is in general similar except for seniority. The impact of differences in coefficients on seniority varies due to econometric probability model used. In case of linear model the impact is positive and equals 6.40% but for logit and probit model the impact is negative and equals 2.71% and 0.90%, respectively.

Conclusions

As a result of carried out analysis we obtained estimates of net efficiency indicators of active labor market programs. The decomposition allowed to estimate impact of each characteristic of the unemployed to the value of the indicator. Moreover the analysis showed that a type of the probability model doesn't influence significantly the estimates of the net efficiency indicator. Moreover percentage differences in characteristics and coefficients have similar tendencies.

Possible direction of future research is to estimate net efficiency indicator with various methods and compare them. One can use model-based parametric methods and for example kernel-based nonparametric methods or matching-based methods.

The Economic Cycle and the Innovation Activity of the Polish Industry System

JEL Classification: *L52; P51; O12; O25; O31; O38; O47*

Keywords: *innovation; economic cycle; system; nation; industry*

Abstract: Industrial structures in the “catching up” type of countries usually are not too competitive in nature, and mainly they differ in the low share of high-technology products in the international trade. The aim of the conducted studies was an attempt to search for directions, as well as the power of impact of different phases of the business cycle on the innovation activity of the Polish industrial system. Consequently, this was to allow to determine the boundary conditions for the national network of innovations and its model structure, which would take into account the specificity of Poland. The methodical part of the paper was based on the theory of probability (probit modelling). Based on the analysis performed based on 5209 industrial companies (questionnaire survey) it was stated that in the prosperity phase the implementation of the innovation activity is significantly higher than in other phases of the business cycle. On the other hand, during recession and stagnation, the innovation activity is a less common phenomenon, but is not completely abandoned. Research results did not confirm the occurrence of the counter-cyclical approach to the conducted innovation activity in the national industrial system. The economic situation is thus an important factor, which influences the decision whether to undertake, activate or, in some cases, limit the innovation activity in companies. Therefore, there is a need to take into account the existing market conditions in the programming of the innovation policy within the impact on the phenomenon of the innovation processes in Poland

Introduction

In Europe there is noted the systematic, but slow process of recovery from the economic crisis, what is confirmed by various economic indicators in individual member states of the European Union. This allows an optimistic look into the near future. This does not change the fact that the observed state of slowdown can still take a long time. Entities operating in this cycle phase are under the peer pressure and often decide on strategies of cost reduction in a short period of time, without devoting much time to the exploration of factors responsible for the creation of the long-term competitive advantage, understood as the innovation strategy (Barett et al., 2009). In a short period of time, the lack or limitation of financing such activity of the companies may result in the stretched or reduced budgets for creating and implementing new technologies, what will ultimately lead to delays in developing new products and processes, limitation of their quality, and even stopping the part of the innovation projects.

The problem of the influence of the conjunctural cycle on the innovation activity of companies is not a new phenomenon, but it still remains in the area of interest of the science, what is confirmed by the publications constantly appearing in this field on both the national and foreign market (Dominiak, Churski, 2012, pp.54-77; Etkowitz, Leydesdorff, 2000, pp. 109-123; Archibugi et al., 2013, pp. 1247-1260; D'Este et al., 2012, pp. 482-488). At the company level, literature in economics shows the diverse influence of the economic slowdown on the dynamics of innovation expenditures. There is the dispute broadly described in this scope. Traditionally, investments into new technologies should be treated as the counter-cyclical measure for companies operating on the market, because limitations taking place in the downturn influence the level of their profitability, what generates the imperative to seek paths to obtain higher productivity. Thus, according to the concept of "creative destruction" of J. Schumpeter, the crisis creates new perspectives for economic entities (Schumpeter, 1939). As the result, many of them should aim to reorganise the structures and improve the quality of own innovation activity. A manifestation of this approach may be the R&D sphere personnel, which during the crisis is subject to the natural phenomenon of "work hoarding". That is, the most qualified employees are "stored" in the company thanks to the lower qualification personnel (Soete, 2009). This generates new potential possibilities to develop the organisation. In turn, the lost profits resulting from the limited labour demand of the directly manufacturing employees should be, during reces-

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

sion, a contribution for the new companies for new investments in the area of technology (Stiglitz, 1993; Aghion, Saint-Paul, 1998, pp. 279-303; Canton, Uhlig, 1999, pp. 239-266). As it is known that the chances of bankruptcy of the companies, which do not implement the reorganisation programs, are higher in the recession phase (Aghion, Saint-Paul, 1998, pp. 279-303).

Despite many logical and common sense arguments that the innovation activity of companies should be counter-cyclical in nature, in literature there often in parallel exists a notion that managers of the companies do not treat the innovation activity differently than its remaining functions. This means that this activity should have the cyclic nature. In the modern economy, generation and implementation of new technologies, mostly the fundamental ones, is delayed during the recession, and companies are waiting for the next wave of recovery (Shleifer, 1986, pp. 1163-1190; Francois, Lloyd-Ellis, 2003, pp. 530-550). In this situation there is no scientific consensus in the area of veracity of the Gerhard Mensch's „acceleration of innovation” hypothesis of 1975, assuming that innovations, especially the radical ones, are more often implemented in the recession phase as an attempt to search new opportunities for companies willing to survive on the shrinking market (Clark et al., 1981, pp. 308-322).

The economic situation is an important factor, which can often influence the decisions about taking or abandoning the innovation activity by industrial companies, both in Poland and in the more developed countries. The Polish industrial system due to its underdeveloped, but improving, character more often depends on the changes taking place in its closer and further environment, and therefore in more developed countries. Studies conducted in the SME manufacturing sector in Spain in 2013 confirm and at the same time generate equivocal conclusions in the analysed sector, and they come down to the following theses (Madrid-Guijarro et al., 2013, pp. 578-601): (1) innovation of small and medium industrial companies decreases during the economic crisis, (2) types of the implemented innovations in the Spanish SME change in different economic conditions, and what is extremely interesting, (3) innovation has a beneficial influence on the results of companies both during the economic development and the recession. The obtained results of studies show that the innovation strategies in the SME sector, despite different phases of the economic cycle, have a significant impact on the efficiency of its functioning and these conditions should be included in the planned and implemented innovation policies. This provides

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

the rationale to conduct analyses in terms of the intensity of involvement in a variety of innovation activity due to changes of the business cycle phases.

Therefore, it can be concluded that the discussion in the studied area was not completed, and the economic impact on the technological changes in the companies seems to be a phenomenon more heterogeneous in nature than it has been previously thought. The analyses presented in the work aim to, even a little, enrich the current state of knowledge in this area, especially in an attempt to explain the conditions of functioning of the economic systems in the “catching up” type of countries.

The essence of the innovation systems are the relations taking place between the individual participants of the market forming the network of links. However, this does not mean that the innovation systems operate in a vacuum, because they are embedded in specific economic conditions. Research conducted by Joint Research Centre (JRC) in the area of assessing the influence of the market conditions on the innovation activity of the economy became the reason to undertake an attempt to assess these phenomena in Poland (JRC, 2010). The results of the analyses conducted there still confirm the ambiguity of this phenomenon and its impact on the innovation activity. Thus, the question remains unresolved: is the economic boom or recession the factor stimulating the companies to adept pro-innovation attitudes?

The primary objective of the study was, therefore, the attempt to search for directions, as well as the power of impact of the economic situation on the innovation activity of companies within the Polish industrial system. Consequently, this was to allow the determination of boundary conditions for the national network of innovation and its model structure, which would take into account the specificity of Poland. The effects of original research presented in this article are only a part of the conclusions, which were obtained as a result of the conducted multi-threaded analyses in the country over the last six years.

The exemplification layer of the paper was based on the study in detail exploring the Polish industry. The studies were conducted based on the questionnaire conducted on a group of 5209 industrial enterprises (the number of sent and correctly completed questionnaires), including 4615 enterprises with the exclusive national capital, 281 – with the foreign capital and 313 enterprises with the mixed ownership structure. Due to the lack of funding of the conducted studies they were spread in time and lasted six years (2007-2012). The simultaneously created database of companies is constantly updated, because the works on the attempt to repeat the studies

18-19 June 2015, Economics and Finance**

in next provinces are underway. The basic path of data collection was the procedure connecting the initial telephone conversation with the submission of the questionnaire form by mail. The complementary forms included the telephone interview or acquiring the filled in questionnaire by e-mail, or fax. The incorrectly filled questionnaire, depending on the character of the mistake, has essentially disqualified it from the opportunity to participate in subsequent stages of the study. The structure of the studied companies approximately corresponded the data presented by the Central Statistical Office. However, unlike the studies conducted in it, there was also taken into account the micro-enterprises sector, what is an incidental phenomenon in the scale of our country, trying to present holistically the way of functioning of the national industrial system in Poland.

All analyses were static and were conducted in the three-year arrangement, referring to the methodological standards over the R&D sphere and innovations conducted in the OECD countries. Because of this there was the possibility to conduct analysed for a longer period of time, without a significant impact on the final results of the study..

Methodology of the research

The methodological part of analyses was based on the theory of probability. The group of eighteen variables included:

a) the occurrence of expenditures on the innovation activity in the companies, but in connection to their structure, that is the R&D sphere, investments in new machines and technical equipment, as well as buildings, constructions, lands and investments in new computer programs,

$$Y_{1i} = \begin{cases} 1, & \text{if expenditures exist} \\ 0, & \text{if expenditures doesn't exist} \end{cases}$$

b) implementation of new processes and products, taking into account the specific solutions in this regard, and thus new products and new technological processes,

$$Y_{1i} = \begin{cases} 1, & \text{if implemantation exists} \\ 0, & \text{if implemantation doesn't exist} \end{cases}$$

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

c) cooperation in the area of the innovation activity in terms of the subject, that is with suppliers, competitors and recipients, as well as universities, JBR and foreign research institutes.

$$Y_{1i} = \begin{cases} 1, & \text{if cooperation exists} \\ 0, & \text{if cooperation doesn't exist} \end{cases}$$

Independent variables, which were used in the study, are the three economic phases: revival, stagnation and recession, which were identified by entrepreneurs based on information about the incomes earned in the last three years. If the incomes in the company increased in the studied period it was assumed that it is in the revival phase. If the incomes decreased – in the recession phase, and when they did not change: in the stagnation phase.

$$X_{1i} = \begin{cases} 1, & \text{if enterprise declares economic prosperity} \\ 0, & \text{if enterprise declares doesn't declare economic prosperity} \end{cases}$$

$$X_{2i} = \begin{cases} 1, & \text{if enterprise declares economic recession} \\ 0, & \text{if enterprise declares doesn't declare economic recession} \end{cases}$$

$$X_{3i} = \begin{cases} 1, & \text{if enterprise declares economic stagnation} \\ 0, & \text{if enterprise declares doesn't declare economic stagnation} \end{cases}$$

Based on this selection of independent and dependent variables there was an attempt to define the interactions occurring between the prosperity phase, in which the company can be found, and the actual innovation activity (financial, implementation and innovation cooperation). However, taking into account the fact that the subject of the study covered the industrial system in Poland and not the single company, then obtained conclusions with the induction method and thanks to the applied statistical tools apply to the whole group of entities. While the probability values approximated in the analytical part of the article are crucial to determine the poten-

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

tial effectiveness of the instruments of the innovations policy – its directions and force of impact.

The adopted independent variables are a set of reference planes, which illustrate the innovation activity of industrial companies, adopted on the basis of the methodology commonly used for the OECD countries since the 80s of the last century (OECD, 2005). There was distinguished the set of features describing the innovation activity of industrial companies at the input (expenditures) and the output (implementation and cooperation). At the same time, to date, the synthetic measure describing the innovation activity on the industry level has not been developed, although the attempts of its system recognition can be found in the literature (KE, 2013). However, they often encounter greater or lesser criticism due to the heterogeneous nature of this activity, difficult to be brought to a common denominator, and the applied measures have specific and, at the same time, limited use.

The statistical verification of models was conducted based on the Wald's *Chi*-square statistics, while the verification of parameter relevance with the *t*-student test using the asymptotic standard errors of assessment. There were adopted the confidence limits at the level of +/-95% – for the model and its parameters. Due to the number of estimated models it was decided to present only those, which meet the condition of the statistical significance – both of the whole model, and its parameter (of the considered factor).

It is also worth noting that both the dependent and independent variables had the binary character. On one hand, this is connected with the fact of necessity to collect a significant number of the properly filled questionnaires – the system study, and on the other, the maximal simplification of questions included in it. This does not change the fact that the nature of the questions asked was consistent with the international methodological standards and practice adopted in this field. For this reason, it was only decided to form the univariate models – the lack of continuous variables on the input allowing for more precise conclusions, however, stressing the directions of the statistically significant connections found between the variables adopted for the study. This proved to be sufficient for the evaluation of the studied phenomena. Based on the theory of probability, there can be estimated the chances of occurring of particular areas of the innovation activity provided that there exist the selected boundary conditions and, this, plan and strengthen the effects of impact of the innovation policy instruments.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

In case when the dependent variable gets dichotomous values, there is no chance to use the multiple regression, commonly applied in the quantitative phenomena. An alternative for such a situation is the use of the probit regression. Its advantage, undoubtedly, is the fact that the analysis and interpretation of the results is similar to the classical regression method. Methods for variable selections, as well as testing the hypotheses, thus have a similar pattern. However, there are differences, which may include, among others: more intricate and time-consuming calculations, as well as calculating values and creating residue charts, which often do not provide anything new to the model (Stanisz, 2007).

In case of a model, in which the dependent variable takes the value of 0 or 1, then the expected value of the dependent value adopted for the model may be interpreted as the conditional probability of the execution of the given event, taking into account the determined values of the independent variables. The applied modelling of this probit type allowed to evaluate the chance of existence of diverse behaviours within the scope of the innovation activity depending on the previously adopted boundary conditions.

Conducting all calculations has been done with the use of the *Statistica* software. Due to the aesthetics of the presentation of the results of the conducted studies, it was decided to present only the basic properties of the econometric models, which met the assessment criteria of the significance of the parameters and models, at the same time resigning from the developed form of presentation, however, taking into account the calculated standard errors, assessment statistics of the model significance as a whole and the probability of occurrence of the phenomena.

All variables adopted for the study, therefore, both the dependent and independent variables, are binary in nature, that is they reach the values of 1 or 0, and therefore the interpretation of the study results has been conducted based on the structural form of the model and achieved probability values. The positive sign by the parameter means that the probability of the event of the innovative nature is significantly higher in the distinguished group of industrial companies in relation to the rest of the group. The probit type of modelling is a very effective research tool, however, mostly in case of large, but at the same time statistical research samples, where the dependent variable takes the qualitative form.

As it has been already mentioned in the introduction, the study was conducted based on the sample of 5209 industrial companies in Poland. The structure of the studied companies from the point of view of the size and technology is presented by the table below.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

Table 19. The structure of industrial enterprises by firm size and technology level (in percent)

No	Firm size	Poland	Technology level	Poland
1	Micro (<10)	36,3	Low	52,2
2	Small (<50)	36,3	Medium low	29,6
3	Medium (<250)	21,5	Medium high	13,2
4	Large (>249)	5,9	High	5,0

Source: own study based on questionnaire research evidence.

The conducted analyses were statistical in nature, what is important from the viewpoint of maintaining the comparability of data and they were conducted in the three-year arrangement with methodological standards of research over the innovations conducted in the OECD countries (OECD, 2005).

The economic prosperity and the innovation activity of the industrial companies

Subjecting a group of companies declaring boom to the probit modelling there were obtained interesting and homonymous study results. For all analysed areas of innovation there were obtained statistically important parameters with the positive sign, without exception. This means that industrial companies are statistically more often prone to undertaking any of the considered innovation activities in the revival phase than in other phases of the economy cycle (cf. Archibugi et al., 2013, pp. 1247-1260). These positive dependencies can be observed both for the financial expenditures incurred for research and development, implementation of new technological processes, and the innovation cooperation, and this process is referred to in the literature as “creative accumulation” (Pavitt et al., 1999, Malerba, Orsenigo, 1995, pp. 47-65). Thus, the obtained results of studies confirm the meaning of supporting this group of entities with different instruments of the innovation policy, either on the national or regional level. Moreover, already at this stage of solutions, in the Polish industrial system, doubts are caused by the counter-cyclical hypothesis of Gerhard Mensch – “acceleration of innovation”.

Considering in detail the values of probabilities, however, we can observe several other interesting probabilities. Firstly, there is a wide diversity between the mathematical value of chances in the areas of financing and implementation, and the innovation cooperation. Companies in the boom period, although more often than other entities, finance and implement new solutions, still they are less often interested in entering into cooperation relations, mostly horizontal (Jasiński, 2014; CSO, 2012). High probability values are obtained for the investment into fixed assets (0,83), including the purchase of machines and devices (0,75) and computer software (0,59),

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

implementation of new products (0,59) and technological processes (0,81), with emphasis on the new methods of their production (0,55).

In the area of the innovation cooperation, entities are more often interested in the vertical connections – with suppliers (0,31) and recipients (0,25), when the horizontal ones are very rare, regardless of the considered cooperation entity (chances close to zero).

In summary, companies in the prosperity period are significantly more likely to implement different forms of innovation activity, mostly in the R&D work area, investment in new fixed assets, implementation of new products and technological processes in the production systems or the vertical innovation cooperation. However, not all indicated areas should be potentially supported by different mechanisms of the innovation policy. This mostly results from the fact of reaching the probability value much above the average (certainty of events). In this situation, there should be considered the meaning of the company support, which regardless of the occurrence of instruments of the innovation policy will implement different forms of the innovation activity (displacing efficiently operating market mechanisms). Thus, the directions of stimulation in the revival period should hover around the following activities: the R&D activity, investment in new buildings, implementation of new products and methods of their production, innovation cooperation along the supply chain. In terms of others, we will deal with 1) the situation of market displacing by the state policy (high probability values), and 2) with non-system attempts to stimulate the innovation activity – high costs and its low effectiveness (low probability values).

As a result of the conducted studies we can observe that the period of the economic acceleration favours the system of acceleration of the technological progress of the Polish industry and basically at this stage of its development it should be supported by instruments of the innovation policy, however not in every area. Such “intelligent” stimulation should accelerate technological changes in the industry, what in turn will contribute to the system, high and self-sustaining auto-dynamism of innovation in Poland.

Recession and the innovation activity of the industrial companies

In the analysed period, 916 industrial companies declared that they were in the recession period (18,6%). They constituted a relatively small percentage of the analysed group of entities, and in addition, taking into ac-

count the occurrence of mostly positive trends in the economy during the analyses, the obtained information can be considered reliable.

Source: own study based on questionnaire research evidence.

As expected, since the period of prosperity had a positive and system influence on the innovation processes, time of recession is responsible for the opposite phenomenon (JRC, 2010). This time, in sixteen out of eighteen potential econometric models, the parameters and models as a whole, reached the statistical significance. The lack of important dependencies was observed only for the innovation cooperation with the PAS units and foreign scientific units, what means that the indicated activity does not decrease significantly during downturn. In other cases, all parameters reached the negative sign, and thus the recession period has a system and negative influence on the innovation behaviours of the studied companies.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

Analysing the achieved probability values, we can observe their strong internal differentiation. However, there are lacking the ones, which take very high values, as it happened in the revival phase. Despite the economic slowdown period, companies are still intensely interested in financing (apart from ED works and investments in new buildings) and implementation of new products and technologies, as in the case of other, more developed countries, what may suggest the cyclic independence of these areas (OECD, 2009; Paunov, 2011, pp. 24-35). Chances for such phenomena are contained in the scope of 47%-63%. However, in case of the implementation of new technological processes, their internal structure is highly diversified. Only the implementation of new production methods is characterised by the relatively high probability (0,39), although, at the same time, twice larger than others, that is the new by-production and support systems.

The establishment of innovation cooperation less often takes place in the recession period. Its greatest chances can be observed again in case of vertical links in the supply chain – with suppliers and recipients (over 18%), what still significantly differs from the phenomena of financing and implementation of new solutions. In other cases, probability oscillates around zero.

Summing up, the potential support in the recession phase with the “visible hand” mechanisms (innovation policy) in Poland should apply to a small number of areas. Particularly susceptible to acceleration are the investments in new machines and technical equipment (0,56), purchase of the computer software (0,50), implementation of new products (0,47) and production methods (0,39). The others reach low, or very low probability values, and the attempts to support them will have the characteristics of non-system, isolated and secluded actions without the effect on the industry as a whole. In other words, the acceleration of innovation processes using the instruments of the innovation policy during recession should be performed with great caution and focus of efforts on the narrow group of areas prognosticating the system effect, according to the concept of “intelligent specialisations”.

**Economic stagnation and the innovation activity
of the industrial companies**

In 27,3% of the studied cases it was declared that the companies are in the stagnation phase with unchanged incomes in the analysed period. Since we have encountered the polarizing approach to the implementation of

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

innovation processes in the revival and recession, it was expected that the stagnation phase will become the bridge connecting the mentioned opposite phases of the economy cycle.

p<0,05

Source: own study based on questionnaire research evidence.

However, it did not happen. It turned out that there were estimated, like in case of the “economic slowdown” variable, sixteen models with statistically significant parameters. The only change applied to the innovation cooperation and consisted of the lack of models for the cooperation with competitors, and the appearance of foreign scientific units. However, what is the most important is the fact that in all models the parameters reached the negative values. And thus, the phase of economic stagnation has a system effect on the inhibition of innovation processes in the Polish companies. Moreover, the power of this negative impact, taking into account the

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

achieved probability values, is similar to the one from the recession period, and sometimes it is even higher.

The potential directions of support of the innovation activity should apply to investments in new machines and technical equipment (0,61), purchase of computer software (0,51), implementation of new products (0,53) and methods of their production (0,41). Chances for the innovation cooperation reach very low values and are once again the domain of relationships along the supply chain. This does not change the fact that they do not have chances for a system innovation dynamism of the industry while undertaking the attempts to stimulate them.

In conclusion, the stagnation phase has a system and negative influence on the implementation of the innovation processes in the Polish industry, like in the recession period. Thus, companies are more often interested in the limitation of the risk connected with this activity than the attempt to anticipate the market events. Entrepreneurs themselves adopt the expectant and conservative position. This is all the more disturbing that the strongest fluctuations apply to areas, which by definition should be long-term in nature (independent on the business cycle), like the R&D activity or innovation cooperation. This reflects mainly the acute treatment of these functions and the lack of noticing of their strategic potential (Marceau, 2002, pp. 209-221). Taking into account the fact that the Polish economy is slowly coming out of the stagnation phase, in the near future we should not expect the high innovation dynamism. This does not change the fact that there exist areas of potential support directions of the discussed activity, despite the adverse market conditions.

Conclusions

After analysing the relationships taking place between the economic prosperity and activity in the sphere of innovation activity in the national industrial system, it can be observed that this phenomenon is mostly cyclical and is shaped like in other countries. During the period of revival, there can be observed the increase of interest in financing and implementing new technologies, while during recession and the economic stagnation, the entities resign from conducting the innovation activity. Therefore, at this stage the hypothesis of Gerhard Mensch about the innovation acceleration in the economic downturn cannot be positively verified. Such a phenomenon, of course, has both advantages and limitations, because from one perspective, the cycle changes influence the market verification of the risky ventures.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

While on the other, the innovation activity has a long-term significance and dimension, and thus, the high volatility may disrupt the natural rhythm of creating new solutions, or their transfer and implementation.

Based on the conducted studies, it can be stated that the business factor systemically illustrates the innovation behaviours of the industry in Poland, what is evidenced by the number of statistically significant estimated profit models. Although all areas of the discussed activity have been described, we can observe significant differences within the achieved probability values. High chances of phenomena are usually noted for the areas of financing (outside the R&D sphere) and implementation of new technological solutions, when the innovation cooperation in Poland is very rare, especially with the institutional R&D sphere. This demonstrates the low maturity of the national industrial system in the possibility of the broad entering into horizontal innovation interactions. Thus, this area in principle should not be temporarily supported by mechanisms of the innovation policy, both on the national and regional level, until it can independently systemically accelerate the innovation processes. Otherwise, the attempts to stimulate this type of relationships will be incidental, isolated and secluded in nature, without affecting the system as a whole. After analysing the existing main directions of the country's influence on the innovation activity in our country, it should be stated that unfortunately we are dealing with such mechanisms, and they constitute the core of the Polish innovation policies implemented on the national and regional levels. System changes according to the evolutionary time perspective, however, require time, so that it can be able to initiate the natural and adequate immanent systemic auto-dynamism, and consequently, obtain the base ability to accelerate innovation processes, which in turn will subject itself to the successful stimulation with mechanisms of the state policy.

The use of the probit type of modelling has in an interesting way illustrated the shape, as well as innovation mechanisms found in the national industrial system. According to the author, it can constitute an interesting alternative for the studies of the dynamics of phenomena. In terms of statistics, so far they have not reached satisfactory time series, and what goes with it, they do not allow the calculations and the appropriate inference. Therefore, it is an attempt of the systemic understanding of the discussed economic phenomena.

Taking into consideration the achieved study results, the support of innovation activity in Poland should be differentiated depending on the phase of the business cycle. Such a mechanism should contribute to a significant-

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

ly more favourable influence of the state policy and its individual support instruments on the system and research and developmental innovation activity of industrial companies.

**Income Inequality by Method
of Non-weighted Average Absolute Deviation:
case study of Central and Eastern European
Countries***

JEL Classification: *C13; D31; I32*

Keywords: *income inequality; index; comparison; method of non-weighted average absolute deviation*

Abstract: The presented article uses the method of non-weighted average absolute deviation for expressing income inequality in the 11 selected Central and Eastern European Countries. Specifically, the analysis of income inequality is done for Poland, Czech Republic, Slovak Republic, Austria, Slovenia, Hungary, Romania, Bulgaria, Latvia, Lithuania and Estonia. Based on the determination of income inequality in the article there is made an analysis of development of income inequality, including the subsequent inter-regional comparison in the context of the degree of income inequality in a given human society and economy. The text of this article is organized in 4 parts, after Introduction follows the analytic chapter where is primarily the method of non-weighted average absolute deviation explained. The third part contains the empirical analysis of income inequality and the

Conclusion highlights some major conclusions of detailed analysis made in chapter 3. The analysis of income distribution of 11 European households between years 2005-2013 and its order is made in deciles based on empirical data from the Statistics on Living Conditions and Welfare published by Eurostat.

Introduction

Income inequality was and also is a natural part of every economy and its society. Income inequality in essence means that different people or different groups of people will reach different income and this income dispersion determines how much the great range of individual income in society at the economy is. (Turečková & Kotlánová, 2014a, pp. 240-247) Phenomenon of poverty and inequality accompanies human society, almost from the very beginning of its existence. (Lapáček, 2007) By Samuelson and Nordhaus (2010) is the invisible hand of the market very effective at allocation of resources and production of goods and services, but can produce simultaneously very unequal distribution of income. Stiglitz (2007) also admits that between efficiency and equality, there is a substitution relationship and therefore to achieve equality is usually required to give up parts of effectiveness. There are many possibilities how to look on or measure standards of living in selected countries. One of the best known is GDP per capita. Despite the fact that this indicator could reach relatively large value, it does not predicate differences of incomes in society. Another indicator we could hear about very often is average wage. Not even its amount is guarantee of economic well-being. It is usual that over 50% of working population of the country cannot reach this amount. One of the best known and used measures of income inequality is Gini coefficient and its graphical representation through Lorenz curve. It could be supplemented by Robin Hood Index and S80/S20 Ratio which are used as other methods of comparison of income inequality. (Turečková & Kotlánová, 2014b, pp. 1063-1057)

The ability to measure and define income inequality is essential for the subsequent analysis of the determinants of income inequality which is given to the context. For example imperfect financial institution causes income inequality as well as inefficient capital allocation (Daisaka et al., 2014, p. 4) or technological changes are often identified as one of the driving forces behind recent rises in inequality. (Lemieux, 2008, pp. 21-48) This can be given in context of Rosen (1981, pp. 757-775) who take the view that one reason that impact of technological changes on income distribution is the well-known “economics of superstars” because technologies

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

enable the top talents to capture increasingly large share of the market. For more information about relationship between income inequality and the knowledge economy see Peng (2014).

Income inequality also resides on spatial dimension where an increase in regional integration associated with the amelioration of inequality at one level usually corresponds to a reproduction of inequality at higher geographical levels (Novotný, 2007, p. 575). For example you can also see Paredes et al. (2012, pp. 1 – 33). Williamson (1965, pp. 3-47) proposes that unequal initial endowments imply a spatial income disparity, but market mechanisms, mainly through labor and firm mobility, lead to the decline of any regional disparity in the long run. Also interesting is the impact of income inequality between households on the housing market. This is partly due to the spatial dimensions, which according to Dewilde and Lancee (2013) there is a positive relation between inequality and crowding and also higher income inequality is associated with lower housing quality.

This article is characterized by introducing and using alternative method for measuring, expressing and analysing income inequality in case of Central and Eastern European inhabitants in the period of years 2005–2013. Among well-known methods how to measure income inequality belong traditionally Lorenz curve, Gini coefficient, Coefficient of income inequality S_{80}/S_{20} (or Quintile share ratio or S_{80}/S_{20} Ratio), Atkinson index, Theil index, Robin Hood index and Variation coefficient. For more information about these methods see for example Atkinson (1970, pp. 244-263), Dalton (1920), Lapáček (2007), Litchfield (1999), Schutz (1951, pp. 107-122) or Wolff (2009). Analysis of income inequality is focused on method of non-weighted average absolute deviation that is not normally used in context of income inequality. The great advantage of using this method is its mathematical-algebraic procedure for calculating the coefficient expressing the degree of inequality directly adapted to the data format in which are data of income distribution provided by statistical organizations. In previous researches was proven extremely positive and high correlation between the results and evaluation of income inequality by here used method and standard methods, such as the Gini coefficient, index S_{80}/S_{20} or Robin Hood index. (Turečková, 2015b, 2015b) Analysis of income inequality through this mentioned method will be based on empirical data of Eurostat in the chosen period of time for 11 selected European countries, namely for Poland, Czech Republic, Slovak Republic, Austria, Slovenia, Hungary, Romania, Bulgaria, Latvia, Lithuania and Estonia.

The rest of the article is structured as follows: the next section provides same theoretical introduces and propositions of method of non-weighted average absolute deviation and its decomposition. Also discusses the advantages and disadvantages of using this method in the context of measures of income inequality. Section 3 contains the analysis of the income inequality in selected European countries using the method of non-weighted average absolute deviation. There is also mention the development of income inequality during analyzed period of time with evaluation of countries and their ranking. Finally the Conclusion concludes with some general comments.

Methodology of the research

Method of average deviation reflects the degree of variability, defined as the arithmetic average of the absolute deviations of individual values of observed indicators from the selected value (given point) (for more information about method of absolute average deviation see for example Tuleja (2009) or Babu & Rao (1990). This method can be also named as Method of mean absolute deviation. Generally, the deviation is reckoned from the ideal value, recommended value, central value that is constructed as some type of average, median, mean of the data set and other. This value chosen here understands the value for the ideal distribution of income in society, ie. the value of expressing absolute equality in income for each inhabitants. In general absolute deviation is constructed on the basis of this formula 1:

$$d_i = |x_i - (x)| \quad (1)$$

where: d_i presents the absolute deviation from i-th indicator,
 x_i presents the i-th indicator (data element, variable),
 (x) is the chosen given point.

Indicator (x) is the ideal percentage value of income which get in concrete the percentage of households in society, for example, 10% of households get precisely 10 % of total income ($(x) = 10\%$). Variable x_i presents real household's money income cumulated into relevant deciles, quintiles, quartile and other. Here we can give an example, that 30% of households got 16.7% of total income in Czech Republic in 2010 ($x_i =$

16.7%). Own value of non-weighted average absolute deviation we obtained from the formula 2:

$$\bar{d}_i = \frac{\sum_{i=1}^p |x_i - (\bar{x})|}{n_i} \quad (2)$$

where: \bar{d}_i presents the average absolute deviation from i-th indicator,
 n_i presents the number of values of i-th indicator that we have available,
 (\bar{x}) is the arithmetic mean of i-th indicator.

Particular form for using this method is to set the time integrated value of the index (3) for relevant evaluation of selected indicators during analysed period of time. Based on this calculated index we can determine the intertemporal ranking of the chosen regions or countries or identify differences between them. The value of intertemporal integrated index we compile by following formula:

$$INI_p = \frac{\sum_{i=1}^p |\bar{d}_i|}{n_i} \quad or \quad D_{ii} = \frac{\sum_{i=1}^p |\bar{d}_i|}{n_i} \quad (3)$$

where: INI_p is an integrated index calculated using the average absolute deviation, where $INI_p \in \langle 0, 100 \rangle$,
 D_{ii} integral index for income inequality (special label).

Integrated index (INI_p) express the average value of variable \bar{d}_i during analysed period of time. Integrated index in context of measuring income inequality will be marked as D_{ii} (deviation of income inequality). Both value of non-weighted average absolute deviation and amount of integrate index can have values from 0 to 100 and if value of non-weighted average absolute deviation and amount of integrate index is lower (the more close to 0) than less income inequality is between the richest and poorest households in society. Perfect income equality in the society would occur in a situation where both values would come out zero.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

The intertemporal integrated index based on methods of non-weighted average absolute deviation is useful for simple comparison of income inequality in large number of societies (communities) together during a long period of time. It is also much easier to use and apply the method of non-weighted average absolute deviation to express income inequality than count Gini coefficient because the results of both methods are essentially identical (Turečková, 2015a, 2015b). As it was mentioned in Introduction there were done another two studies. There were compared results of the level of income inequality measured through 3 methods, using new methods of non-weighted average absolute deviation and two standard methods: Gini coefficient and S80/S20 Ratio. The correlation between them was very high which means that there is a high significant dependence between selected variables. Since the correlation between the results obtained with the method of non-weighted average absolute deviation and Gini coefficient is significant, it is advisable to use the method of non-weight average absolute deviation to express the deviation in income inequality instead of Gini coefficient which calculation is considerably more difficult. The negative of using the intertemporal integrated index is that the value of this index does not tell us anything about the development (or the trend) of income inequality in the society during the time.

From a methodological perspective, the work is based on secondary data gained by Eurostat, concretely from the Population and social conditions, Living conditions and welfare, Income distribution and monetary poverty, Distribution of income by deciles as a share of national equivalised income for 11 European countries: Poland, Czech Republic, Slovak Republic (Slovakia), Austria, Slovenia, Hungary, Romania, Bulgaria, Latvia, Lithuania and Estonia. The covered period includes years 2005-2013 because of missing credible data which is not available for a longer period.

Income is understood as a total disposable income of a household that is calculated by counting personal income received by all members of the household plus income received at household level. Disposable household income includes all income from work (employee wages and self-employment earnings), private income from investment and property, transfers between households and all social transfers received in cash including old-age pensions. (Eurostat, 2015)

Calculations of value of non-weighted average absolute deviation and integrated index (D_{ii}) are based on calculations using formulas (1), (2) and (3). All these measures of income inequality were described in the text

above. The software used was MS Excel. All calculations and graphical analysis is author's own.

Empirical analysis and findings

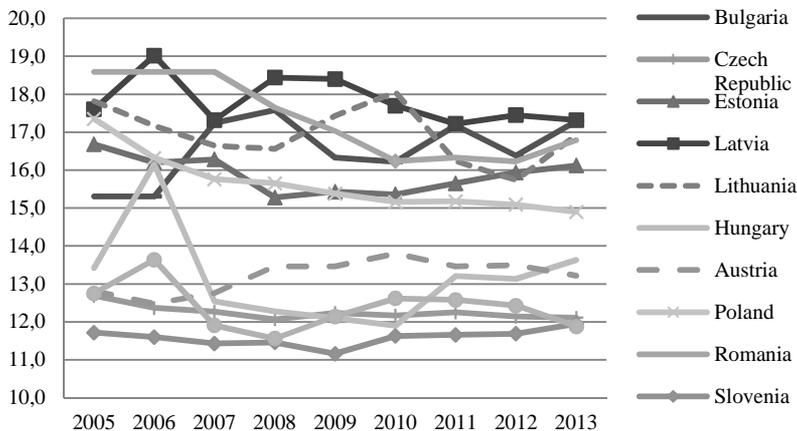

Empirical analyses were made on the basis of the share of national equivalised income of 11 Central and Eastern European countries household's data from Eurostat (2015). Subsequently on the basis of the data we compute through method of non-weighted average absolute deviation the values that by the set way characterize income inequality. We can also compare these values to determine the income inequality between countries or characterize development of income inequality in relevant country over the period of time.

Figure 1 is showing the development of values of average absolute deviation for selected eleven European countries for the years 2005-2013. It shows that the best income equality from analysed group of countries has Slovenia. Through the graphical interpretation of income inequality shown in Figure 1 clearly see the natural division of the countries analysed in two groups. Group of countries with higher income equality forms already mentioned Slovenia, followed by Slovakia, Austria, Czech Republic and Hungary, whose development in income inequality has a considerable dynamic, which is not desirable. Group of countries with higher income inequality, whose values of income inequality calculated by non-weighted average absolute deviation are higher than the first group, consists of all three Baltic States, Poland, Romania and Bulgaria.

The Figure 1 shows that only Poland achieved continuous decline in income inequality (by 2.5 point) during the period. How we can see also from this graph, there were not any significant changes in income inequality/income equality in other 9 selected countries (except Bulgaria, where its increased value indicating income inequality by 2 points) in the set period of time.

Source: own calculations based on Eurostat (2015).

Table 1 complements Figure 1 and presents a value of income inequality calculated by non-weighted average absolute deviation in analyzed European countries for years 2005-2013. Table 1 is supplemented with a multicolored range where the darker the tint value in the cell is given by the country for that year characterized by higher income inequality. Countries with a light tint are doing in the context of income equality better than those for which it is darker tint values.

Table 23. Values of income inequality calculated by non-weighted average absolute deviation (\bar{d}_i) in selected European countries (11) for each year supplemented with a multicolored range

Geo/Year	2005	2006	2007	2008	2009	2010	2011	2012	2013
Bulgaria	15.3	15.3	17.2	17.6	16.3	16.2	17.2	16.4	17.3
Czech Republic	12.7	12.4	12.3	12.1	12.2	12.2	12.3	12.1	12.1
Estonia	16.7	16.2	16.3	15.3	15.4	15.4	15.7	15.9	16.1
Latvia	17.6	19.0	17.3	18.4	18.4	17.7	17.2	17.5	17.3
Lithuania	17.8	17.2	16.6	16.6	17.4	18.1	16.2	15.7	16.9
Hungary	13.4	16.2	12.5	12.3	12.1	11.9	13.2	13.1	13.6
Austria	12.8	12.5	12.8	13.5	13.5	13.8	13.5	13.5	13.2
Poland	17.4	16.3	15.8	15.7	15.4	15.2	15.2	15.1	14.9

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

Romania	18.6	18.6	18.6	17.7	17.0	16.2	16.3	16.2	16.8
Slovenia	11.7	11.6	11.4	11.5	11.2	11.6	11.7	11.7	12.0
Slovakia	12.8	13.6	11.9	11.6	12.1	12.6	12.6	12.4	11.9
Mean	15.2	15.4	14.8	14.7	14.6	14.6	14.6	14.5	14.7

Source: own calculations based on Eurostat (2015).

There is also data about a mean value for each year. Comparing these values, we find that in the course of 9 years, income inequality across groups of countries as a whole declined (from 15.2 point to 14.7 point). If you simply compare values between year 2005 and year 2013 then there is an improvement in income equality in the Czech Republic, Estonia, Latvia, Lithuania, Poland, Romania and Slovak Republic. Deepening income inequality occurred in Bulgaria, Hungary, Austria and Slovenia.

The value of (intertemporal) integrated index D_{ii} representing the level of income inequality in society in each country is shown in Table 2. This index averages the values obtained by the non-weighted average absolute deviation for the whole analysing time series. Based on the amount of this index we can compile the ranking of countries based on their uniform distribution of income in the society.

Table 2. Amount of intertemporal - integral index for income inequality and the ranking of countries in context of income inequality for selected European countries (11), lined up

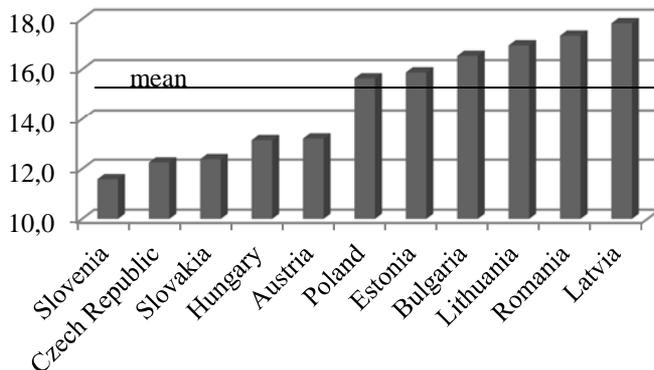

In- dex/Geo	Slovenia	Czech Repub- lic	Slovakia	Hungary	Austria	
D_{ii}	11.59	12.26	12.39	13.15	13.22	
Ranking	1	2	3	4	5	
In- dex/Geo	Poland	Estonia	Bulgaria	Lithuania	Romania	Latvia
D_{ii}	15.64	15.88	16.54	16.95	17.34	17.83
Ranking	6	7	8	9	10	11

Source: own calculations based on Eurostat (2015).

Graphs of the results (see Figure 2) of the index D_{ii} are more easily legible and complete Table 2. The income inequality was lowest in Slovenia during years 2005-2013, where the intertemporal integrated index was 11.59. About 0.67 points after Slovenia, in second place with the lowest income inequality, was Czech Republic and about 0.8 points, in third place was Slovakia (Slovak Republic) within the selected group of countries followed by other analysed European countries. Average value of the index,

mean, is 14.8 points. The worst situation in context of income inequality was in Latvia where the amount of integrated index was 17.83 points for time period 2005-2013.

Figure 2. Development of values of income inequality calculated by non-weighted average absolute deviation (\bar{d}_i) in selected European countries (11), (2005-2013)

Source: own calculations based on Eurostat (2015).

Figure 2 shows another interesting fact. From a geographic point of view, countries with higher income equality concentrated in the central European region while countries with higher income inequality make up the group Baltic countries, along with Poland, Romania and Bulgaria, it means the Eastern European countries acceding to the European Union at the end of the integration process and countries in transition problematic process. For further research, the question is whether that income inequality is not related to the geographic location, which in turn determines the other factors involved in the distribution of income in society.

Conclusions

There is a lot of methods, procedures and approaches to measurement and describing income inequality in our economy and our society. In this paper is paid attention to new (alternative) method of measuring and expressing income inequality through method of non-weighted average absolute deviation. It was used to map changes in income inequality of eleven Central and Eastern European countries, concretely of Poland, Czech Republic, Slovak Republic (Slovakia), Austria, Slovenia, Hungary, Romania,

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

Bulgaria, Latvia, Lithuania and Estonia between years 2005-2013. There was also assembling the ranking of these countries in context of a more equal distribution of income in a given society. It was done on the basis of intertemporal integrated index. The highest income equality reached Slovenia from the analyzed group of countries; the worst income inequality was in Latvia.

The second conclusion presented in this paper is that non-weighted average absolute deviation method can expand the existing portfolio of methods for measuring and expressing income inequality between households in society because of its comparatively simple feasibility while the results are comparable to standard and traditional methods of measuring income inequality.

**Dispersion of Inflation Expectations
in the European Union During the Global
Financial Crisis**

JEL Classification: *C33; C42; D84; E31*

Keywords: *inflation expectations; survey data; global financial crisis; European Union*

Abstract: Inflation expectations, both their median and dispersion, are of a great importance to the effectiveness of monetary policy. The goal of this paper is to examine the impact of the global financial crisis on dispersion of inflation expectations in the European Union. Using European Commission's survey data, we find that in the early phase of the crisis the dispersion dropped rapidly but then, after Lehman Brothers' collapse, the trend reversed and these fluctuations cannot be explained by movements of inflation rates and other commonly used factors. We also observe that, in the new European Union member states, the initial drop of the dispersion was weaker whereas the subsequent rise was stronger as compared to the old member states.

Introduction

The starting point of this paper is that inflation expectations underlie many consumption and investment decisions, price and wage setting, and thus determine inflation itself. Therefore, low, stable and well-anchored inflation expectations play a decisive role not only for maintaining price

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

stability over longer periods of time, but also for the effectiveness of monetary policy in case of such major shocks as the global financial crisis. Nevertheless, uncertainty brought about by the global financial crisis may have significantly modified the way economic agents formulate their inflation expectations. For instance, greater dispersion of inflation expectations might negatively affect the monetary policy environment and welfare in crisis-affected countries.

Dispersion (or heterogeneity) of inflation expectations seems to be an inherent feature of economic systems. There is a growing body of literature confirming the need to analyze this phenomenon. According to Mankiw et al. (2003), disagreement about future inflation is an interesting variable both for theoretical and practical considerations, because it may be vital for understanding macroeconomic dynamics. High dispersion of inflation expectations changes allocation of resources and implies significant adjustment costs for a large number of individuals if they realize that the actual inflation rate deviates from their initial expectations (Gerlach et al., 2011). Different opinions about future inflation can invite agents to speculate which in turn may delay or distort actions undertaken by the central bank. They may alter the term structure of interest rates and thus threaten fiscal discipline. They may also affect the distribution of income and wealth as persistence of forecasting errors implies making suboptimal decisions (Gnan et al., 2011). Besides, the dispersion of inflation expectations can be used as a measure success of inflation targeting countries (Capistrán & Ramos-Francia, 2010). Finally, dispersion of inflation expectations is of a great importance for monetary unions where persistent differences in inflation expectations among countries may create external imbalances, destabilizing trade and affecting the effectiveness of supranational monetary policy. Therefore, low dispersion of inflation expectations in a monetary union (such as the euro area) can be treated as one of indicators of convergence in terms of inflation rates (cf. Gnan et al., 2011).

There are several papers referring to the dispersion of inflation expectations in the euro area after the onset of the global financial crisis. For example, Badarinza & Buchmann (2009) observed that in the euro area the disagreement about inflation expectations started to rise in the second half of 2007 and rose further with the ongoing crisis. Galati et al. (2011) reported that in the euro area the cross-sectional dispersion of long-run inflation expectations increased in the beginning of 2009. Gerlach et al. (2011) found that the dispersion of professionals' forecasts of five-year inflation in the euro area reached its maximum in the beginning of 2009. Then it started

to decline, but it did not return to its pre-crisis level. Gnan et al. (2011) noticed that the dispersion of inflation expectations calculated for the euro area as a whole dropped sharply in 2007 and did not change significantly until the third quarter of 2008. Afterwards, disagreement increased again surpassing the level observed before the introduction of the euro.

However, none of these papers formally examine the impact of the crisis on the dispersion of inflation expectations controlling for factors that influence the expectations like the level of inflation and its variability. Here, we fill this gap and test empirically the hypothesis that uncertainty brought about by the global financial crisis increased the dispersion of inflation expectations in the European Union countries. Contrary to the previous papers, we focus not only on the euro area, but we also include the other members of the European Union. Therefore, we can highlight the important differences between the old and new European Union member states.

The remainder of the paper is structured as follows. In the subsequent sections, we present the data and the measures of ordinal variation that we use in our empirical analysis, and the methodology that we employ. Then, we estimate the impact of the global financial crisis on the dispersion of inflation expectations in the European Union and examine whether all countries observed similar developments. For comparative purposes we also conduct analysis of perceived inflation. We conclude in the final section.

Data on expected, perceived and actual inflation

Our choice of measures of dispersion of inflation expectations (discussed in the next section) is dictated by the character of available data. We use qualitative data on expected and perceived inflation taken from the European Commission's Business and Consumer Survey (European Commission, 2015). The survey is conducted monthly in the European Union member countries as well as candidate states. Each month about 300-2000 complete questionnaires are gathered in each country. We are interested in two questions for which respondents can give answers according to a five-option ordinal scale, i.e.:

Question 5: How do you think that consumer prices have developed over the past 12 months? They have: (a) risen a lot, (b) risen moderately, (c) risen slightly, (d) stayed about the same, (e) fallen, (f) don't know.

Question 6: By comparison with the past 12 months, how do you expect that consumer prices will develop in the next 12 months? They will:

(a) increase more rapidly, (b) increase at the same rate, (c) increase at a slower rate, (d) stay about the same, (e) fall, (f) don't know.

Our sample covers the period 2003-2014. We decided to start our analysis a year after the introduction of the euro because of significant disturbances associated with formation of inflation expectations in the newly established euro area. We consider the current members of the European Union, but because of data unavailability we have to exclude Luxembourg, Denmark, Ireland and Croatia from the sample. Besides, we do not analyze aggregate measures of inflation expectations, because they seem to mask heterogeneity observed across countries (cf. Gnan et al., 2011).

Furthermore, as the actual inflation rate is an explanatory variable in our models, we also extract monthly data on the HICP inflation (Eurostat, 2015) for the period 2002-2014 (with the first 12 observations being used to calculate the yearly changes of the inflation).

On the whole, we work on a balanced panel with 24 countries and 144 monthly observations.

Measurement of dispersion of inflation expectations

Empirical analyses of dispersion of inflation expectations are usually based on such measures as the standard deviation (e.g. Galati et al., 2011; Gerlach et al., 2011) or the interquartile range (e.g. Mankiw et al., 2003; Trehan & Zorilla, 2012). However, these both measures cannot be calculated directly for qualitative data as they require quantification. Therefore, following Badarinza & Buchmann (2009) and Gnan et al. (2011), we use the index of ordinal variation proposed by Lacy (2006) as the baseline measure of the dispersion of inflation expectations.

If f_1, f_2, \dots, f_k denote cumulative category shares, then the index is calculated as follows:

$$IOV_{Lacy} = \sum_{i=1}^{k-1} f_i (1 - f_i).$$

In our case, $k = 5$, because when calculating the dispersion measures, we always exclude the last answer (*f*) *don't know*, and adjust the remaining frequencies proportionally to keep the sums equal to 100%. For $k = 5$, the index coincides with the measure proposed by Berry & Mielke (1992).

Lacy's index is designed to measure an average difference between categories and has very intuitive properties: it takes values from the range

$[0, 1]$, where the value 0 is attained only when all respondents give exactly the same answer. On the other extreme, when $w_1 = w_5 = 0.5$, then the value of the index equals 1.

For the robustness check purposes, we also consider two other measures. The first is an alternative index of variation for ordinal variables introduced by Leik (1966). The index assesses an average deviation from the median and is given by the formula:

$$IOV_{Leik} = \frac{\sum_{i=1}^k w_i |i - m|}{0.5(k - 1)},$$

where by m we denote the median. It holds similar properties as the Lacy's index.

As for the second measure, we follow the standard practice from the literature and assume the normal distribution of inflation expectations. Then, we estimate the relative standard deviation σ/π^e of the distribution using the formula developed by Berk (1999):

$$\frac{\sigma}{\pi^e} = \frac{2}{z_1 + z_2 - z_3 - z_4},$$

where

$$z_1 = \Phi^{-1}(1 - w_a),$$

$$z_2 = \Phi^{-1}(1 - w_a - w_b),$$

$$z_3 = \Phi^{-1}(1 - w_a - w_b - w_c),$$

$$z_4 = \Phi^{-1}(w_e),$$

σ denotes the standard deviation, π^e is the expected inflation rate, $\Phi^{-1}(\cdot)$ stands for the inverse of the normal cumulative distribution and w_i is the frequency of answer i . In case of $w_e = 0$, we set $\Phi^{-1}(w_e) = -3$.

All three dispersion measures are conditional on the perceived inflation. Basically, this comes from the conditional nature of question 6 in which respondents are asked about their expectations relative to the perceived price change in the previous 12 months (question 5). (In fact, the answers (d) and (e) to question 6 are stated unconditionally, but, nonetheless, they

are rarely chosen by respondents.) Throughout the paper, we do not try to use unconditional dispersion measures, because it would inevitably involve estimating cross-section correlations between expected and perceived inflation which seems to be a demanding task without the survey microdata.

Methodology of the research

To assess the impact of the crisis on the dispersion of the inflation expectations we estimate following fixed-effects panel models:

$$y_{it} = \alpha_{0i} + \alpha_1 \pi_{it-1} + \alpha_2 (\Delta \pi_{it-1})^2 + \alpha_3 d_{ce,t} + \alpha_4 d_{cm,t} + \alpha_5 d_{cl,t} + \alpha_6 d_{euro,it}, \quad (1)$$

where y denotes the dispersion measure, π – the annual inflation rate, $\Delta \pi_t = \pi_t - \pi_{t-12}$ is the annual change of the inflation rate, d_{ce} , d_{cm} , d_{cl} – dummy variables representing phases of the financial crisis, d_{euro} – dummy variable for the euro adoption period.

We set the common dating of the crisis period for all countries, since we are unable to find any comparable criterion for setting the crisis time frames in all countries separately. As already suggested by equation (1), for the purpose of our study, we distinguish three phases of the crisis. The early phase (d_{ce}) that lasts from July 2007 to August 2008 is associated with a swift rise of inflation rates caused by the oil price rally. At the beginning of this period, the first worldwide shortages of liquidity occurred and stock market indices began to fall. The middle phase (d_{cm}) starts in September 2008 when Lehman Brothers collapsed and lasts 10 months, until June 2009. This phase is characterized by a severe recession and rapidly decreasing inflation rates. Finally, the late, or recovery, phase (d_{cl}) ends in June 2010, when GDP growth rates approximately returned to their pre-crisis levels and inflation started to accelerate again. That month, the European Central Bank also ended its first covered bond purchase programme, intended to support a specific financial market segment that had been particularly affected by the financial crisis.

Of course, the proposed phasing is somewhat arbitrary. However, establishing the exact time frames of the global financial crisis is a difficult task as far as expectations are concerned. The difficulties result from the interplay of two features of expectations: forward-lookingness and non-observability. Observed events as well as rich statistical data offer a sound guidance for the real-economy crisis dating, but are less useful if expectations are investigated. Unfortunately, there is no reasonable alternative to

them. Nonetheless, our phasing allows us to highlight the evolution of the expectations' dispersion during the whole crisis.

In our analysis we also include control variables to capture the correlations between the dispersion measures and the inflation rate as well as the trend in the inflation rate $(\Delta\pi_t)^2$. The dummy variable for the euro adoption period is equal one for six months before the euro adoption date and for another six months after the date and zero otherwise. It accounts for the changes of the inflation expectations caused by the euro adoption in some new European Union countries.

Results

In table 1, we present the main results of our analysis. The table contains the parameter estimates of the model (1) for the Lacy's measure of the dispersion of inflation expectations. We report the results for the panel of all studied countries, denoted by full sample, as well as the separate estimates for the panels of old and new EU members.

Table 19. Estimates of panel models for the dispersion of inflation expectations

As far as the full sample is concerned, in the first phase of the crisis, the dispersion was (on average) lower by 0.031 than the theoretical values predicted by other explanatory variables. Then, in the middle phase, the dispersion bounced back and on average was higher by 0.051 than the theoretical levels. Finally, in the late phase of the crisis, the dispersion also re-

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

mained high, although the difference was considerably smaller. Nonetheless, all effects are statistically significant at 0.01 significance level. To put the estimates into the right perspective, they can be compared with the unweighted average unconditional standard deviation of the dispersion measure for all panel countries that is equal to 0.065. From this point of view, the “pure” effects of the crisis do not seem impressive, but one has to keep in mind that they are accompanied by the nonnegligible effects of rapid changes in the other explanatory variables, especially the inflation rates.

Generally, a similar pattern is observed in the old European Union member states. Interestingly, the decline in the dispersion in the early phase of the crisis is almost exactly compensated in the middle phase. This, however, is not the case in the new member states. There, the initial drop is weak, just 0.018, but the subsequent rise is significantly stronger. Likewise, in the late phase, the “pure” effect of the crisis remains stronger than in the old members of the European Union. Finally, our results also confirm that the euro adoption by some new European Union countries was associated with the significant increase in the dispersion of inflation expectations.

To put more light on the differences between the old and new member states, we run country level ordinary least squares regressions of model (1). The results are reported in table 2.

Regarding the early phase of the crisis, the drop in the dispersion is observed almost in all old member states (with the only exception of the United Kingdom), whereas the new member states exhibit more heterogeneous outcomes. Particularly, the weak drop in that group reported in table 1 results mainly from the considerable increases in the dispersion observed in Latvia, Malta and Bulgaria.

On the other hand, there are fewer differences as far as the middle phase is concerned. The significant rise of the dispersion is observed in all countries, except from Spain, Italy, Hungary and Poland. Finally, the heterogeneity of the results becomes stronger again in the last phase. In particular, contrary to the general trend, the dispersion declined in almost all Southern Europe countries.

Finally, we also note that the general conclusions from table 1 do not apply to Poland. Interestingly, the dispersion in Poland was constantly lower throughout the crisis. This might reflect the relatively weak impact of the crisis on the Polish economy, although one has to bear in mind that similar drop was observed in the Southern Europe, where the crisis was by no means mild.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

For the robustness check purposes, we conduct a similar analysis with other measures of dispersion. The results are reported in table 3. As far as the Leik's index is concerned, we do not find any significant differences as compared with the findings already obtained with the Lacy's measure. The two indices differ mainly with respect to their average levels, but the results are correlated strongly.

On the other hand, we find more differences for the standard deviation of the normally distributed expectations. In particular, the “pure” effects of the crisis on the dispersion seem to be weaker in the early and late phase of the crisis. In fact, in the latter case, the effect is statistically insignificant, and simply absent in the new members of the European Union. Moreover, the size of the middle-phase effect is similar for the old and new member states. Nonetheless, the observed differences are generally mild and do not contradict explicitly the general findings reported above.

Finally, in a similar way, we examine the behavior of the dispersion of perceived inflation measured by question 5 of the survey (see table 4). As far as the full sample and the old EU panel are concerned, the results are virtually the same as for the inflation expectations. Surprisingly, we do not find the middle-phase impact of the crisis on perceived inflation in the new member states.

Conclusions

The results of the study document a clear pattern regarding the behavior of inflation expectations in European Union member countries during the global financial crisis. In the early phase of the crisis, the dispersion significantly dropped. However, after Lehman Brothers' collapse, the trend reversed and the dispersion exceeded the typical levels. Therefore, we confirm the findings of Gnan et al. (2011), but contrary to that study we show that the movements cannot be attributed to the behavior of inflation rates and some other commonly used factors. We also estimate the "pure" effects of the crisis on the dispersion in its three phases and show that they are not very impressive compared to the unconditional standard deviation of the dispersion values. Moreover, we highlight that the initial drop of the dispersion in the new European Union member states was weaker whereas the subsequent rise was stronger than in the old member states.

The country-level analysis reveals some interesting deviations from this pattern. In particular, the dispersion was constantly below the typical levels in the Southern Europe countries as well as in Poland and Hungary. The opposite results are obtained for Bulgaria, Lithuania and the United Kingdom.

Naturally, further research could focus on building more comprehensive models including a wider choice of economic and demographic variables. They could analyze not only the overall effect of the global financial crisis on dispersion of inflation expectations, but also more detailed issues such as possible changes in inflation expectations formation (including their unanchoring).

Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

Another possibly important avenue is related to measurement of the dispersion of inflation expectations. In the study, we use the dispersion measures conditioned on perceived inflation that do not take into account the dispersion related to the inflation perception. Employing unconditional measures would definitely put more light on the discussed topic.

**The Review of Theories of Mainstream
Economics on the Example of Economic
Models**

JEL Classification: *E10*

Keywords: *economic model; economics; economic theories; economy*

Abstract: Regardless of the fact that economics distinguishes itself from other social sciences by a high level of formal deductive modelling, it is a social science due to the essence of the economic process where a human is subject and object at the same time. In the recent years this issue has been more frequently emphasized by economists in ongoing discussions. In the discussions a good deal of time is devoted to economic models and, mainly, their relations with the socioeconomic reality and coherence of empirical evidence. The article presents a thesis that some mainstream economic theories have not always constituted the background to their practical applications, which led - and still can - to the dogmatic and inflexible use of model solutions for economic phenomena which are difficult to forecast in a non-variant rigid model. The aim is to critically analyse beliefs about usefulness of universal economic models in the economic reality advocated by mainstream economists and to prove that not all economic models have constituted the background to their practical applications.

Introduction

The necessity of reviewing or even redefining some previous economic theories arose earlier. Nevertheless, these processes have accelerated by the last global crisis. Then, practice visibly showed that some assumptions of theories of economics, including the mainstream theory, become invalid under the influence of the dynamically changing reality.

Mainstream economics (also called neoclassical synthesis) is an attempt to combine different economic theories, mainly the elements of Keynesian theory and monetarism. It is still the most common economic mindset in the world. However, the achievements of mainstream economics are being heavily criticized. The criticism comes down to objections to the methodological sphere and not noticing and omitting close relations between economy and other areas of social life, assumptions about extreme rationality of economic entities, simplifying model analyses, as well as accepting by its followers the axiom of a perfect information flow and unlimited possibility of using it. Meanwhile, market reactions of economic entities appeared to be different from what in the theory of mainstream economics concerns standard models of a competitive market. Thus, basic dogmas of mainstream economics were criticised severely because they diverged significantly from the economic reality. The negation of the doctrines of mainstream economics caused that, in the 1970s and 1980s, some of its assumptions were liberalized. As part of moderating the assumptions of mainstream economics, above all new theoretical tools were applied which made it possible to analyse imperfectly competitive market structures and, especially, to use in the analysis issues concerning the exchange of intermediate products, monopolistic competition, the meaning of economies of scales and activities of international companies.

L. Calmfors created a list of objections to economists, mainly followers of mainstream economics, among which there was a statement saying that these economists are not able to assess risks, their analyses are in general false, theories are not coherent and models break under their own weight or are incompatible with the reality (Walter, 2011, pp. 40-41). K. Juselius also treats economists, especially those being followers of neoclassical and mainstream economics, with a lot of reserve. In her view, econometrics is certainly a part of economics due to using tools of mathematics, statistics and informatics for studying relations between phenomena in economy, but it is also used to conduct analyses and prepare economic forecasts. However, according to K. Juselius, authors of econometric models attach more

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

significance to their mathematical and statistical precision (they are very often awarded the Nobel Prize for that) than to the reality in which they should be useful. What was mastered to perfection was creating a price index used to indicate an inflation index omitting such elements as a dramatic rise of stock and real estate prices or increasing exchange rates of Swiss franc and other currencies. In economic models, however, many other factors are not considered, e.g. the widening gap between rich and poor or the focus on results and maximum intensification of work, what causes stress and makes a circle of the excluded broaden. In consequence, they do not give answers to our questions which we need (Walter, 2011, pp. 40-41). The issue was emphatically raised by L.Calmfors mentioned before who claims that economists were the cause of the crisis and that: "(...) it is their extensive financial instruments, their policy of low interest rates and deregulation of the financial market that led to the collapse of the Lehman Brothers investment bank and, then, to the financial crisis of global economy in autumn 2008" (Walter, 2011, pp. 40-41).

D. Orrell treats economics, especially the assumptions of mainstream economics, very disapprovingly. D. Orrell identifies mainstream economics with the following ten assumptions (which, incidentally, are accepted by the majority of economists): economy can be described using economic laws, it consists of independent entities, it is stable, rational and effective, it does not favour any sex, the economic risk can be managed thanks to statistics, economic growth can last forever and it is always good and gives us happiness (Orrell, 2010). In should be added that these assumptions serve as the basis for neoclassical economics and other currently dominating theories, among others the efficient-market hypothesis. According to D. Orrell, economics is in such a bad state because mainstream economists are Pythagoreans¹ - from "an initiation" to an approach to forecasting. One becomes an economist through long and expensive (in the Anglo-Saxon countries) studies. There are strong mechanisms for extorting orthodoxy (in the main economic magazines, it is practically impossible to publish studies which challenge the aforementioned assumptions). Mainstream economists (as well as neoclassical ones) seek elegant numerical rationality. Just as

¹ To put it simply: the Pythagoreans thought that the whole world can be described by numbers. Some, no mean - there were to be smooth, perfect numbers. They believed that there is some profound order which special people - those like them - are able to encapsulate in refined theories. Initiation meant that the Pythagoreans were a very elite circle. To join them, one had to meet high requirements: dispose of all possessions, lead an ascetic life and study for five years having taken a vow of silence.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

Pythagoreans, they are willing to ignore inconvenient facts in order to sustain the belief that economy looks as they would like it to look like. The author claims also that mainstream economists try to imitate Newton (the fathers of modern macroeconomics - William Jevons Leon Walras or Vilfredo Pareto - were saying that straight), even though they deal with a completely different sphere of reality. Meanwhile, Newton understood that it is impossible to describe human behaviours in a way that physics does. He wrote: "I can calculate the motion of heavenly bodies, but not the madness of people." D. Orrell explains in an appropriate and accessible way why he criticizes the basic model of neoclassical economics, also accepted by mainstream economics. In his view, it does not correspond to human economy, but the god's, and he gives the following example: "If an economist knocked on your doors and asked you to create the plan of consumption for the rest of life, you could have quite a problem. (...) It would require unlimited computational capabilities" - he writes. Then, he points out that "Mainstream economics assumes that people are highly rational - superrational, and are not subject to emotions. They never overeat or get drunk, they save towards their retirement, the exact amount that is needed - first, they count how much they will need and then, they save money with a meticulous precision. Real people are not like that" (Orrell, 2010).

Many economists being followers of modern mainstream economics have presented the achievements of economics in such a way as if it was a part of applied sciences. Such an approach, however, involves different research methods since a greater precision and ability to forecast are expected from applied sciences than from social sciences. It provokes some reflection that if a degree of methodology of some economic articles is comparable to studies from applied sciences, then one should be prepared that it increases expectations concerning insight and accuracy of answers to many questions related to, among others the last crisis.

Summing up, it can be acknowledged that a big mistake of economic policy in the mainstream theory was universalism established a priori. As a result, mainstream economics has become excessively formalized. It limited economics to rigid and measurable dimensions which were very often included in economic models. Together with complex economic phenomena, such formalism led to mistakes involving a significant simplification of mechanisms functioning in economy. It is impossible to present essential qualitative features using algebraic formulas in economics. The next drawback of modern mainstream economics is assuming that in economy there are "optimal" solutions which can be easily found as a result of the analysis

of an adopted model. It is not possible because assuming that, from the real world one should exclude consumers' irrational behaviours, risk, speculations, enterprise and uncertainty connected with it, which take place in every real socioeconomic life.

The imperfections of mainstream economics presented above show awareness of the necessity for transformation in the theory of economics and socioeconomic practice, and, what is most important, support more extensive research and discussions on possible directions of changes.

Methodology of the research

The scientific aim of the article requires an adequate methodology of research, which will allow to define efficacy and research value of the presented analysis.

The modern economics in its main trends (including main-stream economics) employs a perspective basing on statistical or mathematical methods. In order to obtain data necessary for such a methodology the supporters of the main-stream economics introduce statistical methods in their modified form, i.e. econometrics. This formal approach to economics has lead to a divide between economists focused on direct, practical aspects and the ones who stressed the importance of models created by means of new analytical tools. One has to point out that more often than not many authors have underlined the danger of “mathematization” of economics due to the formal approach or the scientism, i.e. the simplified attempts to uncritically adapt certain methods from so-called “natural sciences” to human or social sciences.

Taking all the above mentioned errors of the main-stream economics into account the author based her methodological assumptions on the following axioms: the methodology employed in the research ought to include not only the research methods themselves (i.e. the choice and creation of the research acts) but also the conditions (psychological, sociological, technical) in order to obtain and formulate the knowledge and foremost the features expected from the knowledge worthy to be considered scientific. Therefore the methodology nowadays should be seen in a wider scope, as a field encompassing not only the methods but their results as well.

The methodology of economics, just as any other disciplinary methodology, has generated its specific methodological terms and criteria employed in the presented article. These criteria are mostly the following:

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

- Theoretical context/paradigm including the hitherto obtained research results (bibliography, social factors and individual motivations).
- The scope of the reality taken under observation, convergence with socio-economic reality.
- The perspective of the research.
- Methodology (such as critical analysis of the bibliography, confrontation of the existing hypothesis and economic laws with the reality, monographic method, inductive method).
- The form of assertions (the terminological apparatus, language).
- Social needs triggered by the research.

Controversies over economic models

Varied approaches towards issues concerning modelling in economics contributed to the development of numerous models, reasons for their divisions and types. In the Polish bibliography of economics, these issues were dealt with in a great deal of studies, parallel to papers in economics, econometrics, statistics and other fields close to economics.

"A model" from the perspective of economics is frequently defined as:

- "A simplified image, model of a part or a set of economic life" (Chodorowski, 1974, p. 81)².
- "A set of assumptions of the economic theory that is a set of conditions where abstract laws are true" (Lange, 1959, pp.123-124).
- "A theory describing a copy of the original which retains the original's properties" (Nowak, 1972, p. 136).
- "A simplified image of economy. With the use of, e.g. a drawing, mathematical equations, a mechanical device, a model shows relations of studied variables" (Czarny, 2011, p. 66).

Obviously, there are many other interpretations of the term "economic model" in Polish and also foreign literature on the subject, however, it seems that few quoted ones make it possible to state that an economic model is an ambiguously defined and relative concept. Since an economic model is explained as a simplified portray of a part of the economic reality, in such a case, in the structure of economics everything can be a model. Then, according to J. Semkow (1977, p. 152), a model is any economic concept because in its simplified form it shows key features of some elements of

² Many definitions concerning this point of view differ from each other because many of them equate the concept of a model with a theory.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

economic life. From this perspective, every economic theory is a model as well; this way some definitions of a model equate it with an economic theory. Despite this correct remark made by J. Semkow, a model in economics is frequently treated as a synonym of an economic theory, however, a model is more often a simplified schema of functioning of national economy or, in general, an economic phenomenon (Marciniak, 2007, p. 31).

Regardless of semantic disputes, an economic model always presents a narrowed image of the economic reality. It is impossible, however, to fully convey the economic reality through applying even extensive, complex and multidimensional models, since real economy undergoes constant evolution caused by social, cultural, political, technical and technological changes, and also by natural disasters. Therefore, a lot of economic models are of a static nature. However, economic laws and theories in static relations cannot be equivalents for reality, since they involve specific context which does not appear in reality. They only copy objective regularities. Thus, models - mainly macroeconomic ones - are based on knowledge from the past. Meanwhile, economy undergoes a constant transformation.

Nevertheless, an economic model helps to create a synthetic image of regularities appearing in economy. Adopting essential assumptions which simplify the economic reality, one can create a model of economy and analyse undergoing in it relations between economic entities. Then, from a nature of these relations and regularities between them, the behaviour of entities in the economic reality can be deduced (Rekowski, 2005, p. 32). The issue was similarly presented by E. Stiglitz who claimed that "in every analysis there are used models which have a form of simple hypotheses concerning reactions of particular units and companies to different changes in a country's policy and a total influence of these reactions on economy. In order to illustrate consequences of various country's activities, everyone use models - politicians as well as economists. However, as opposed to politicians, in their models, economists try to form hypotheses very clearly, in such a way that they are not contradictory to each other and they are in accordance with reality" (Stiglitz, 2004, pp. 22-23). Reality showed that J. E. Stiglitz overestimated prudence and pragmatism of many economists. Moreover, he altered the aforementioned statement. At the economic conference in Lindau in Switzerland in 2012, in which seventeen economic Noble prize winners took part, he stated that macroeconomists have been

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

ignoring undergoing changes for so long that they have lost contact with reality creating unreal economic models (Żakowski, 2011, p. 21)³.

According to J. E. Stiglitz (2004, pp. 22-23), economics, especially macroeconomics, for a few last decades has become a refined academic field, however not very useful in practice. Accuracy of this statement is proved by irregularities and even errors in the assessment of socioeconomic achievements (as the last global crisis revealed), both at the microeconomic (mainly in the evaluation of companies' assets prices and capitals value) and macroeconomic level (e.g. in the evaluation of the value of gross domestic product, GDP). The issue is described at length among others by R. Skidelsky who claims that the global crisis was a result of a wide range of irregularities and errors in the evaluation of assets by private banks and rating agencies. The consequence of these irregularities was largely illusory models (Skidelsky, 2011). This situation has one more alarming side, that is, it provides impetus to marginalizing ethical and moral values. Thus, it is worth emphasizing that it is mainly the lack of obeying ethical rules that led not only to irregularities connected with the system of assessment of socioeconomic achievements, but also to the outbreak of the last crisis.

The economic crisis, situation on financial markets, bankruptcy of many banks and changes in consumer behaviour have given rise to a fierce discussion among economists which focused on the problems related to the socioeconomic theory and practice. The criticism mainly concerned the utilitarianism of models constructed by economists. There were many negative opinions, especially among macroeconomists, on the belief that there is a possibility of devising universal economic models that completely reflect the economic reality. One of the sceptics is P. Diamond⁴ who claims that each individual situation requires a different model, while some economists erroneously believe that once a mechanism or a truth are discovered they should be treated as indisputable. G. Akerlof aptly encapsulated this problem stating that the letter "e" which symbolizes real human behaviour in macroeconomic models has been replaced by "e*" that symbolizes how people should behave according to the author. It is G. Akerlof's opinion that the asterisk should be deleted and replaced by knowledge that stems from research on real human behaviour. In most cases such research has not been conducted yet (Żakowski, 2011).

³ In the article, the author described a debate on modern economics which took place in Lindau and 17 economic Nobel prize winners took part in it.

⁴ Peter Diamond is considered one of the most eminent modern economists together with Stiglitz, Krugman or Roubini.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

T. Lawson (2009, pp. 757, 765) has also heavily criticised the relations between economic models and the socioeconomic reality and their coherence with empirical evidence. He completely negated the application of modelling as a useful method for assessment and recognition of the essence of the socioeconomic reality by claiming that such a reality has "depth or structure; the social relations, rules, positions, power structures and so forth that are typically immeasurable [...]. Social reality, in other words, is of a nature that is significantly at variance with the closed systems of isolated atoms that would guarantee the conditions of mathematical deductivist modelling".

In its nature, the construction of models that reflect the economic reality as accurately as possible is a difficult and complicated task. Many economists state that creating an economic model often verges not only on science but also on art. It is difficult not to agree with such a statement. Building a model that includes all indispensable features of the real world from the perspective of researched problems is not so easy, especially when at the same time it cannot include too many or too little details. An impressive number of variables and their interdependencies in the former case make the essence of the problems disappear in the swath of data. While, in the latter case the simplification will result in a general outline of the analysed aspect and, in consequence, it will not allow to accurately and comprehensibly present the researched problem. Incidentally, the term "art of economics" dates back to J.N. Keynes who divided economics into positive and normative and was later cited by M. Friedman. J. N. Keynes did not create such a division because in reality he divided economics into positive, normative and the art of economics. He emphasised that the art of economics is of a great importance as it is the branch of economics that also concerns economic policy. Therefore, the art of economics requires a judgement regarding reality as it introduces sociological and political variables. According to D. C. Colander, it is inevitable when we talk about economic policy. He elaborates on the topic saying: "the main objection I have to the majority of people in our profession is that they try to combine positive economics with economic policy and draw conclusions about it from models which are not realistic enough from the institutional perspective to be used for such aims" (Snowdon, Vane, 2003, pp. 284-285).

M. Friedman argued that the realism of assumptions is irrelevant and that, what is really important, is the prognostic value of a theory (Snowdon, Vane, 2003, p. 284). D. C. Colander absolutely rejects this notion and claims that everything is dependent on the level of deliberation. According

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

to D. C. Colander, there is no method in macroeconomics to unquestionably test all devised concepts at an empirical level. The author emphasizes that "[...] where you cannot test empirical theorems, the method based on "prognostic value" becomes problematic. There is no proven theory in macroeconomics. We only perceive reality in a general way. The realism of assumptions in such a general understanding of reality plays the main part as assumptions constitute a part of this understanding. The assumptions determine what is perceived. Thus, I believe that Friedman is completely wrong in his view of macroeconomics, however, in a wider sense, if we assume that economics was a science in which one can unambiguously test theorem, I would be more willing to approve of Friedman's views" (Snowdon, Vane, 2003, p. 284).

Considering the above deliberations, it appears there is a considerable group of modern economists that firmly emphasize the significance of qualitative factors in their final conclusions on economic models. Meanwhile, the neoclassical theory, and later mainstream economics, radically divided the quantitative and qualitative manifestations of phenomena, which in practice disregarded the role of qualitative aspects. Thus, the constructed econometric models omitted qualitative elements which could not be included as variables in a model because they were considered immeasurable. As a result, discerning cause and effect relations between individual elements of economy became more complicated as the qualitative manifestations of phenomena and economic processes were disregarded. Economics thereby moved away from real social problems while attempting to gain an image close to the one possessed by applied sciences. In consequence, quantitative analysis methods became of a great importance in mainstream economics as they allowed the balance of each particular element of the economic system to be accurately described. Economists started to be solely interested in aspects that were measurable, countable and could be mathematically expressed.

Naturally, neither theoretical concept nor economic model can ideally recreate the complexities of socioeconomic life. It is necessary to apply a simplified image that concentrates on recurring, representative manifestations of phenomena and processes. Thus, the purpose of a model is not to reproduce reality accurately but to retain the realism of its assumptions.

Conclusions

The conducted analysis of the theory of mainstream economics from the perspective of economic models allows a following conclusion to be formulated: the most often framed reproof of economic models concerned their inaccuracy with the reality of economy. The criticism was also aimed at too much theory in economic models, as well as at an excess of empirical knowledge. According to A. Wojtyna (2009, pp. 36-37), as well as other participants of this discussion, a major part of objections to mainstream economics would lose its strength [...] "if new findings of research conducted on human behaviour by other disciplines (mainly by psychology and neurophysiology) were taken into account to a larger extent." In other words, mainstream economics would be more receptive to behavioural economics⁵, which in recent years without doubt has become one of the most dynamically developing research areas in economics". It is a very accurate insight as behavioural economics is currently perceived as a mature research programme and a separate sub-discipline of economics. D. Fudenberg (2006) points out that the outcome of such research was not only attracting the mainstream economic followers' attention to the irregularity of human behaviour that deviates from a standard model, but mainly building formalized models which generate and explain these irregularities and may be incorporated into larger models. Nevertheless, behavioural economists realize that, on the one hand, their accomplishments cannot be questioned, but, on the other hand, they are aware that an unquestioned

⁵Inception or rather origins of behavioural economics can be dated back to the 1930s. John Broadus Watson and Burrhus Frederic Skinner are considered the founders of behavioural economics. In 1979, however, texts by Daniel Kahneman and Amos Tversky in *Prospect Theory: An Analysis of Decisions under Risk* were published. It was followed by Richard Thaler's *Toward a Positive Theory of Consumer Choice* a year later (Kahneman, D., Tversky, A. (1979). *Prospect Theory: An Analysis of Decisions under Risk*, „Econometrica” 1979, no. 47, p. 313–327; Thaler, R. (1980). *Toward A Positive Theory of Consumer Choice*, „Journal of Economic Behavior and Organization”, no. 1, p. 39–60.). Both of these publications triggered a rapid development of a new field known as behavioural economics. In their works, the authors explained economic theories in the context of psychological basis for human behaviour. Behavioural economics is not a homogenous school, quite the contrary, it consists of a set of different theories including the Michigan School (George Katona), psychological economics (Colin Camerer, Richard Thaler, Ernst Fehr), behavioural macroeconomics (George Akerlof), evolutionary economics (Richard Nelson, Sidney Winter), behavioural finances (Robert Schiller) or experimental economics (Vernon Smith). What all these concepts have in common is the negation of neoclassical convictions that equate a human with *homo oeconomicus* whose characteristics are absolute rationality, drive to satisfy only their own narrowly defined interest and complete self-control.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

introduction of their own research programme may lead to them being excluded from the discourse. This happened to heterodox economics which also presented different research methods and subject of analysis in comparison with mainstream economics, though in a more forceful manner. Mainly, but not only, due to those reasons, relations between mainstream economics and behavioural economics are still weak. In a long-term perspective, according to C. F. Camerer and G. Loewenstein, simplified models based on the assumption of strict rationality will be successively replaced by behavioural models. The assumption of strict rationality, which currently is perceived as an inherent part of economics, in the future will be treated as a useful, special case that stems from more general, behaviourally-substantiated theory (similarly to how the Cobb-Douglas production function or the expected value maximization principle are treated now). At the same time, they emphasize that their approach is not based on an idea of a complete rejection of neoclassical economics, which in general is very useful, but "on modification of one or two assumptions of the standard theory in order to achieve a higher psychological realism" (Camerer, Loewenstein, 2004; Wojtyna, 2009, p. 41). Table 1 shows the main characteristics of mainstream economics and behavioural economics.

Table 1. The main characteristics of mainstream economics and behavioural economics

MAINSTREAM ECONOMICS	BEHAVIOURAL ECONOMICS
Mainstream economics, also referred to as neoclassical synthesis, is an attempt to combine various economics theories, mainly the elements of Keynesian economics and monetarism.	Behavioural economics is a discipline that combines the accomplishments of classical economics and psychology. It is a field of an economic analysis that verifies the assumptions of neoclassical economics on the basis of sociological and psychological research findings.
Main research methods: econometric modelling, deductive and abstract methods, the analysis of economic phenomena from the static and dynamic perspectives, taking into account innovation in built models, devising microeconomic base for a macroeconomic analysis that guarantees internal coherence.	Main research methods: the theory of planned behaviour, experiments that employ more realistic psychological foundations.

Source: own work.

Thus, agreement, consensus or shared beliefs so much needed by modern economies are a procedural content of conditions on which the success of mainstream economics being receptive to behavioural economics depends. However, the success depends on whether the assumptions used in mainstream economic models will be supplemented with qualitative fac-

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

tors. This means that they will also include the ideas of behavioural economics mainly including assumptions that are based on sociological and psychological research findings, as well as the findings of research that apply a similar methodology. As A. Wojtyna (2009, p. 47) noted, this will support making “economic human” resemble “ordinary humans”. The future will show whether and to what extent these changes will be useful in practice. However, due to increasing criticism of models that are often defined as the standard models of mainstream economics, certainly there is a natural need to search for new solutions focused on the usability of economic models in real economy, especially in terms of their forecasting capabilities. This thesis is proved by the fact that none of the intricately built economic models forecasted the crisis. Although, more worrying is the fact that there have not been built any models that would show how to get out of it.

This article has presented the position which claims that for mainstream economics to assertively open up to behavioural economics there is a need for the advocates of the former to be always reflective, think critically and search, as well as to overcome their persistence of adhering to one right ideology, because it blocks the way to complementary changes in economics.

Institutional Determinants of Regional Diversity of Labor Market in Poland*

JEL Classification: *B15; B25; B52; J08*

Keywords: *institutional economics; labor market; institutional unemployment; labor market's institutions*

Abstract: The article will focus on regional diversity of the Polish Labor Market from institutional perspective. The Polish Labor Market is geographically diverse in terms of unemployment and employment rates, and also in terms of economic development. At the end of 2013 the difference between the lowest and the highest unemployment rate in the Polish regions was 12.1% (Wielkopolska located in the West Poland has unemployment rate of 9.6% and Warmia - Mazury in the East has unemployment of 21.7%). The question arises whether this difference comes from the structural or institutional sources? The paper will describe the character of Polish Labor Market whereas in the second part, it will trace the impact of institutional variables such as real wage, Kaitz index and Gender gap on the regional unemployment rate in 2002-2012 in Poland.

* This text was presented during the 26th Annual EAEPE (European Association for Evolutionary Political Economy) Conference 2014, Nicosia, Cyprus, which was held between the 6th-8th Nov 2014.

Introduction

The economic crisis that first broke out in 2008 has taken a tremendous toll on labor markets across the EU. Unemployment figures have increased, while employment rates continue to fall. It has been observed that the crisis has served to accelerate previously existing structural trends, generating increasing inequality, polarisation and atypical employment (Crisis takes its toll: disentangling five years of labor market developments, 2014, p. 27).

In this context, the Polish Labor Market is an interesting example of changing situation. On the one hand in terms of economic growth, Poland remained “green island”, but on the other hand Polish Labor Market remains highly diversified with some structural and institutional problems.

The aim of this paper is to present this regional diversity of Polish Labor Market from the institutional perspective. The intellectual background of this text is based on institutional economics. As North (1990, p. 3) put it: “Institutions are the rules of the game in a society or, more formally, are the humanly devised constraints that shape human interaction”. For labor market the most important are: benefits, participation-friendly schemes, labor taxation, wage setting, employment protection legislation, union density and active labor market policies (skills developments, youth employment and job creation). Such institutions affect the efficiency of an economy. An economy with good institutions is more efficient in the sense that it takes less inputs to produce the same amount of output. Moreover, bad institutions lower incentives to invest, to work and to produce (Sala-i-Martin 2002).

An important part of labor market are also informal institutions such human capital, social capital, religion, customs, norms and type of society. This institutions are especially important for the big labor market with diverse regional field, where cultural factors play a major role.

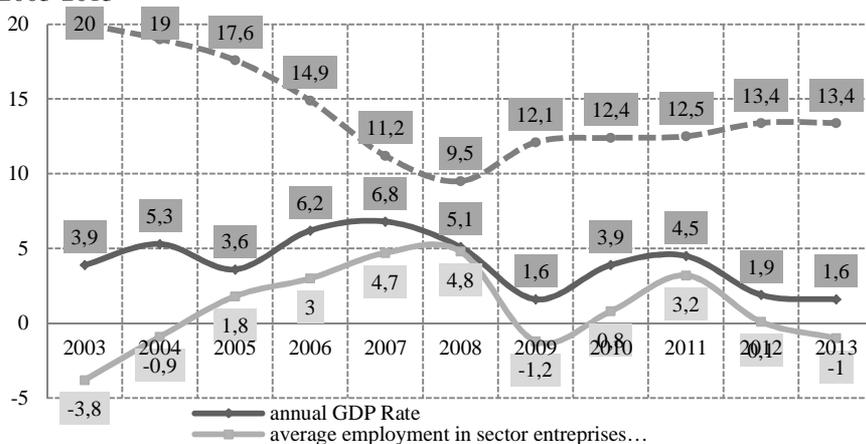

Nowadays problems of Polish Labor Market are geographically diverse - low activities of labor force, especially women and high unemployment. Most of the analysis of this problem is focused on the structural sources, but the interesting question is: how the institutions affect the unemployment and if this impact is the same in all regions of Poland?

In the first part of this paper, I describe the character of Polish Labor Market whereas in the second part, I trace the impact of selected institutional variables such as real wage, Kaitz index and Gender gap on the regional unemployment rate in Poland in 2002-2012.

Institutional characteristics of Polish Labor Market

Not a long time ago, in 2004, Poland was fighting very serious unemployment (20% in 2002-2003). The transformation process imposed a radical change regarding rationalization and restructurization of employment, which was carried out in Poland in two waves. The first wave of restructurization (companies before 1989) was overlapped by the second wave, based on the development of the new IT based economy. Moreover, new restructurization of social services appeared, for example in education or health care. These two processes led, especially after 2001 to employment rationalization, forcing rapid economic growth, generated mainly by increasing productivity and use of new technologies. The situation on Polish Labor Market also has changed after Poland joined the EU system. Common European Labor Market has helped to solve the problem of Polish unemployment. Unfortunately, after 2008 the latest global economic crisis has affected the Polish Labor Market as well and nowadays the rate of unemployment is still 13.4% (see Figure 1).

Figure 1. Annual GDP rate, employment and unemployment rate in the years 2003-2013

Source: own elaboration based on Statistical Yearbooks of GUS (GUS).

While analyzing the data presenting by Eurostat, we do not see a serious problem of unemployment and employment in Poland, but the problem with the overall level of economic activity for the age group 15-64 years (see Table 1). In the years 2003-2013, we observe even a significant de-

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

crease of difference between Poland and EU28 in terms of employment and unemployment. However, European statistics do not show the real situation in Poland, because are based on different definition of working force age (in Poland – 18/59-64 years¹, than in the EU – 15/64 years).

Table 1. Activity, employment and unemployment in Poland vs. EU28

Year	Activity rate (15-64 years)			Employment rate (15-64 years)			Unemployment rate (15-64 years)		
	Poland	EU(28)	difference	Poland	EU(28)	difference	Poland	EU (28)	difference
2003	64	68,9	-4,9	51,4	62,6	-11,2	19,7	9,2	10,5
2004	63,7	69,2	-5,5	51,4	62,7	-11,3	19,4	9,3	10,1
2005	64,4	69,7	-5,3	52,8	63,4	-10,6	18	9,1	8,9
2006	63,4	70,1	-6,7	54,5	64,3	-9,8	14	8,3	5,7
2007	63,2	70,3	-7,1	57	65,3	-8,3	9,7	7,2	2,5
2008	63,8	70,7	-6,9	59,2	65,7	-6,5	7,2	7,1	0,1
2009	64,7	70,9	-6,2	59,3	64,5	-5,2	8,3	9	-0,7
2010	65,3	70,9	-5,6	58,9	64	-5,1	9,7	9,7	0
2011	65,7	71,1	-5,4	59,3	64,1	-4,8	9,8	9,8	0
2012	66,5	71,7	-5,2	59,7	64,1	-4,4	10,2	10,6	-0,4
2013	67	72	-5	60	64,1	-4,1	10,5	10,9	-0,4

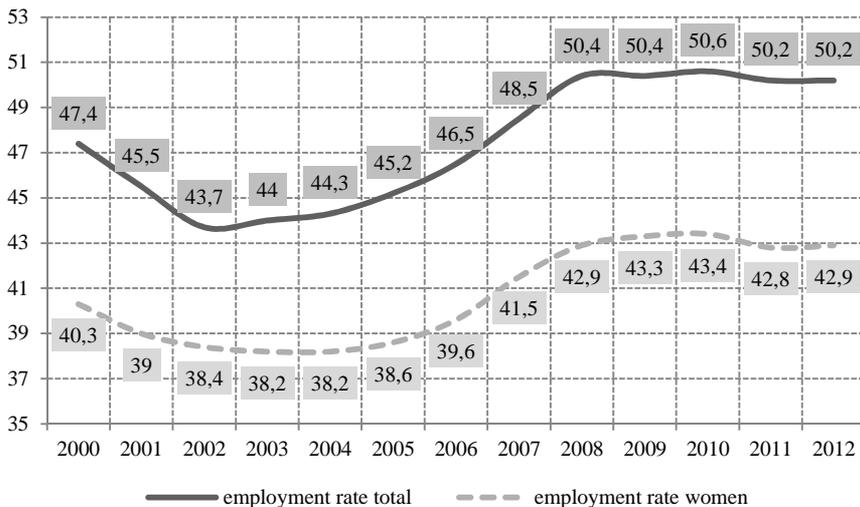

Source: (Rynek pracy w Polsce w 2013 roku, p. 16).

Thus, in Poland we have a lower activity and lower employment than in the EU - particularly of women (see Fig. 2). For example, in 2011 Poland was inhabited by 38.5 million people including 23.6 million people at the working age. Among people of working age – only 16.5 million people were economically active (including women - 7.4 million). In the fourth quarter of 2013, the most important reasons for inactivity were: a pension

¹ In 2013, the retirement age was raised in Poland to 67 years.

(indicated by nearly half of the economically inactive population), learning and raising qualifications, disease and disability (indicated by 13.9% of the economically inactive) and family responsibilities (11.1% of passive population) (Rynek pracy w Polsce w 2013 roku, p. 3).

Figure 2. Employment rate total and women (18-59/64 years) in Poland in the years 2000-2012 (%)

Source: own elaboration based on Statistical Yearbooks of GUS (GUS 2000-2014).

Low economic activity and low employment rates provoke questions about the institutional conditions of the labor market in Poland. Among the most important informal and formal institutions which affect the behavior of the labor market participants we can point out the following:

- a) In the employer's environment:
 - perception of the hierarchy and the distance worker-employer,
 - acceptance of change - the need of regulation,
 - tax system (labor costs, tax wedge),
 - employment protection system (rules for employing, dismissing, and wage setting, eg. the scope and level of wage negotiation and coordination, minimum wage system),

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

- social dialogue (including social goals and ways to achieve them by trade unions and employers' organizations, the level of unionization and wage bargaining system),
 - bureaucratic and financial obstacles for the development of entrepreneurship,
 - existence and size of the shadow economy.
- b) In the employee's environment:
- feminization vs. masculinization of social roles,
 - perception of leisure time and family (*work life balance*),
 - quality of social capital,
 - unemployment income protection (passive labor market policy) and assistance in finding and obtaining work (active policy),
 - social assistance, infrastructure of family support, educational policy, pension system,
 - professional and spatial mobility.

Institutional determinants of unemployment can be divided into those that affect the demand for labor and the supply of labor. The former ones include: employment protection legislation, labor taxation, the system of unemployment benefits, union density, system of wage bargaining. The latter ones - the factors affecting the changes in labor supply: demographic and family policy, earlier deactivation and migrations.

In institutional analysis, the most important problem is the choice of one indicator, which allowed a total assessment of institutional change. In most cases, existing indicators describe reality at the macroeconomic level for the whole country. Therefore they are useful to conduct regional analyzes. However, in order to illustrate national trends in institutional change we can use the following indices:

- Index of Economic Freedom in the labor market developed by the Heritage Foundation (published since 2005);
- Labor Market Efficiency Index published by the World Economic Forum (since 2006);
- Employment Protection Legislation Index (EPL) developed by the OECD.

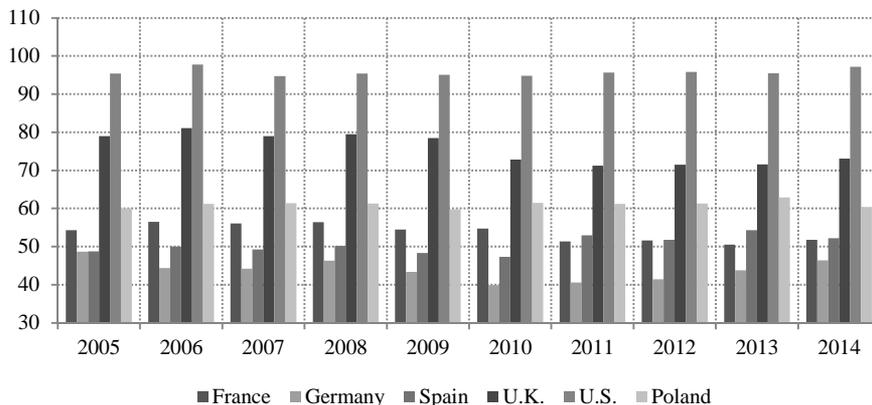

Referring to these indicators, it can be summarized that in terms of freedom in the labor market, Poland is classified among the countries with the average economic freedom (with a score of 60 points).

The best results are achieved by the United States (in 2014 - 97.2 points) and the U.K. (73.1 points). The vast improvement is observed in the Czech Republic (an increase from 57.7 points in 2005 to 84 points in 2014), and

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

the reverse trend - in the case of Slovakia (a decrease from 77.1 in 2008 to 53.6 points in 2014).

Figure 3. Index of Economic Freedom in the labor market in Poland and in selected countries of Western Europe and the U.S. in the years 2005-2014

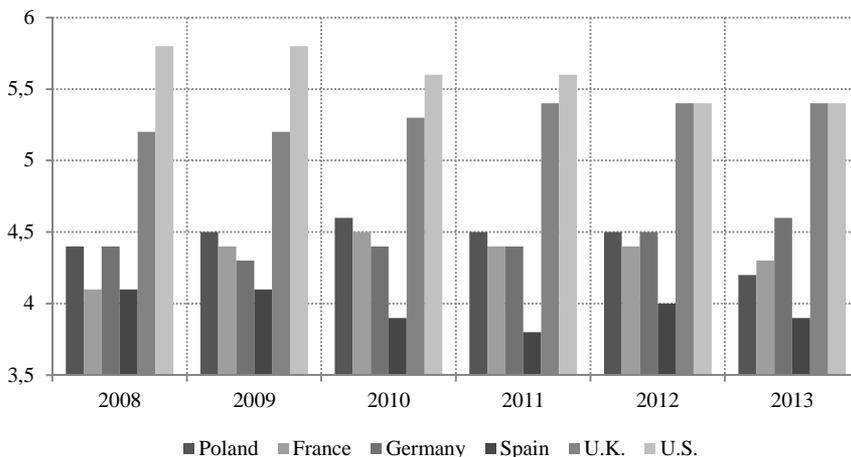

Source: own elaboration based on (Heritage Foundation).

Another institutional indicator is the Index of Labor Market Efficiency which is the component of Competitiveness Index published by the World Economic Forum. Competitiveness is understood here as “*the set of institutions, policies, and factors that determine the level of productivity of a country*”. The level of productivity, in turn, sets the level of prosperity that can be reached by an economy. The productivity level also determines the rates of return obtained by investments in an economy, which in turn are the fundamental drivers of its growth rates. In other words, a more competitive economy is one that is likely to grow faster over time (The Global Competitiveness Report 2013-2014, p. 4).

In comparison to selected countries of West Europe, Poland obtained results similar to the French market (France with a score of 4.31 in 2013 ranks 71 out of 148 countries, and Poland with a score of 4.20 ranks 80), and far better than Spain (ranks 115 with a score of 3.93). In contrast, in Eastern Europe, the Czech Republic and Slovakia reached a better result in 2008 (4.7), but currently indexes for Poland, Hungary, the Czech Republic and Slovakia remain at a similar level (in 2013, the Slovaks have achieved the result 4.24 and ranks 76, Poles and Czechs - 4.20 and rank 80 and 81, and the Hungarians - 4.18 and ranks 85).

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

Figure 4. Labor Market Efficiency Index in Poland and in selected countries of Western Europe and the U.S. in the years 2008-2013

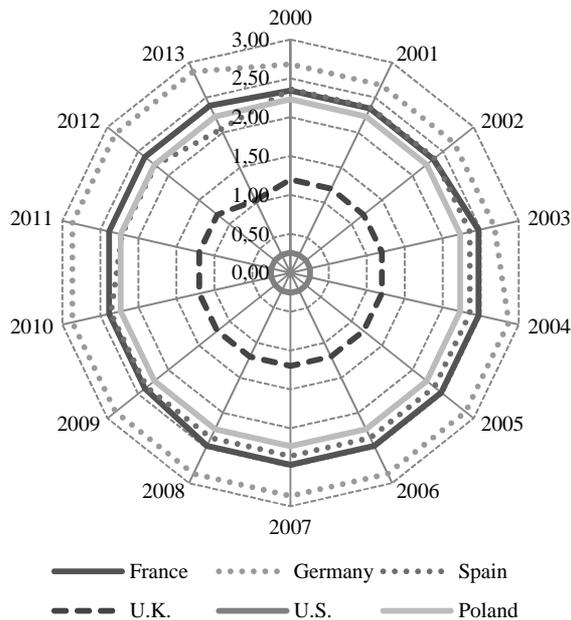

Source: own elaboration based on (The Global Competitiveness Report 2008-2009; 2009-2010; 2010-2011; 2012-2013; 2013-2014).

To evaluate the flexibility of the labor market we can refer to employment protection legislation (EPL) index applied by OECD. This indicator measures the procedures and costs involved in dismissing individuals or groups of workers and the procedures involved in employing workers on fixed-term or temporary work agency contracts. EPL index takes value from 0 to 6 (the higher the number, the bigger protection of the labor market) and concerns three areas: individual dismissal of workers with regular contracts, additional costs for collective dismissals and regulation of temporary contracts.

In general, Poland in the years 2000-2013 was characterized by a relatively liberal labor laws in comparison with other transition countries, both in terms of regular contracts, as well for collective dismissals. Meanwhile, in the case of regular contracts we don't observe changes in index of employment protection legislation for Poland (in contrast to the Czech Republic and Slovakia, where the EPL indicators are falling). The exception is the protection of employment for collective dismissals, where the rate fell from 3.38 in 2003 to 2.88 in 2004. We can therefore conclude that the labor market in Poland has been largely liberalized but the decline of employment protection mainly reflected in the development of atypical forms of employment. At the turn of the 20th and 21st centuries the workers with tem-

porary contracts counted 5-6% of total employment, while at the end of the decade, their share exceeded 25%. As a result, Poland has become the country with the highest ratio of fixed-term workers within the EU. In 2011, the percentage of fixed-term workers in Poland was 26.9, which was almost twice as much as the EU27 average - 14.1 (Bartosik, 2012, p. 35).

Figure 5. Employment Protection Legislation for workers with regular contracts in Poland and in selected countries of Western Europe and the U.S. in the years 2008-2013

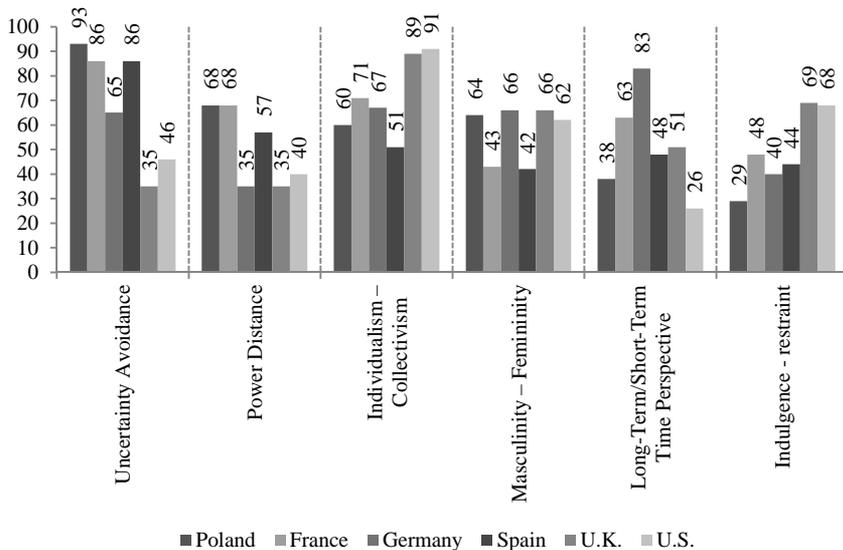

Source: own elaboration based on EPL OECD data (OECD 2014).

Finally to analyze the institutional fundamentals of labor market, we should refer also to informal institutions. Without going into detail of sociological research, we can quote only the research of Geert Hofstede, Gert Jan Hofstede and Michael Minkov, which shows the type of society and helps to understand the Polish character of labor market. G.Hofstede analyzed five dimension of culture which characterize each population (Hofstede 1991). The first was the distance to authority (distance of employees or citizens from superiors or leaders). In other words, this dimension assesses attitudes toward hierarchy. The second dimension is the level of

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

individualism - whether it is important to achieve the objectives of the individual, or of the whole group. It also draws attention to masculinity or femininity of society. A community which is more male define clearly social roles of gender and in the case of interests' differences seek confrontation. In contrast, more feminized society sets both sexes the same requirements and pays attention to the quality of interpersonal relations. In this society the conflicts are solved by negotiation. Societies which are more male are characterized by less professional activity of women. An important dimension is also avoidance of uncertainty - if we accept the changes. Society expecting predictability (avoiding uncertainty) protects itself by creating numerous laws and regulations. Therefore in the case of labor market they will not be willing to deregulation.

Figure 6. Dimensions of national cultures in Poland and in selected countries of Western Europe and the U.S.

Source: own elaboration based on (Hofstede G., Hofseted G.J., Minkov, 2011, pp. 70-72; 105-106; 150-151; 201-202; 260-262; 289-291).

The research of Hofstedes and Minkov based on *European Social Survey* and *World Values Survey* indicates that Polish society is still male with a medium level of individualism and a large distance to the authorities, pending predictability and avoiding uncertainty, with short-term oriented

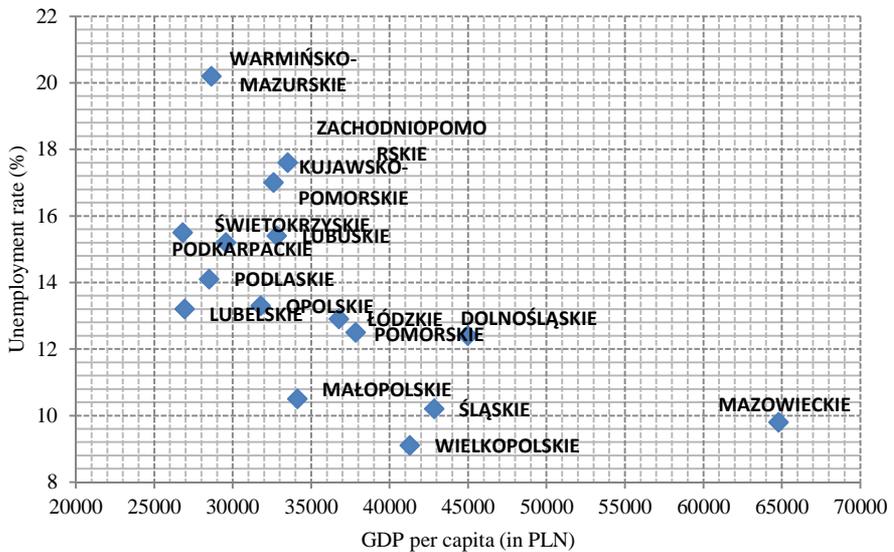

strategies and rather restrictive (Hofstede G., Hofseted G.J., Minkov, 2011, pp. 70-72; 105-106; 150-151; 201-202; 260-262; 289-291).

Regional diversity of Polish Labor Market

Having presented trends on the Polish Labor Market, I would like to answer the question whether this market is homogeneous? The question is: how the institutions affect the unemployment and if this impact is the same in all regions of Poland?

First, using the index of GDP per capita, which shows indirectly scale of household income and comparing it to the unemployment rate (data for 2011) we can show the placement of the Polish regions in terms of the regional markets development.

Figure 7. GDP per capita and unemployment rate in 2011 by region

Source: own elaboration based on regional BDL data (GUS 2014).

Figure 7 confirms the existence of the underdeveloped regions, such as Warmia-Mazury, Podkarpackie, Swietokrzyskie and Lubuskie (regions close to the eastern border – so called the Eastern Wall), but also Zachodniopomorskie (region at the western border) and Kujawsko-

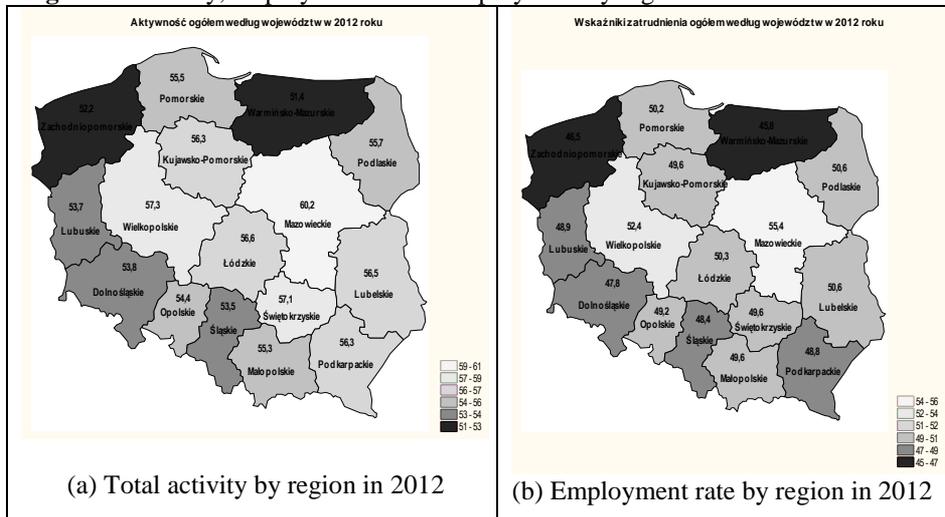

Pomorskie (central Poland). At the opposite extreme we have Mazowieckie with the capital Warsaw – standing out from the other regions, and further Wielkopolska, Silesia and Malopolska.

Such important developmental difference between regions in Poland is due to many factors, including long-term underdevelopment and civilization gap which lead to the threat of permanent marginalization of certain areas. This marginalization is supported by the structural and institutional conditions of local markets.

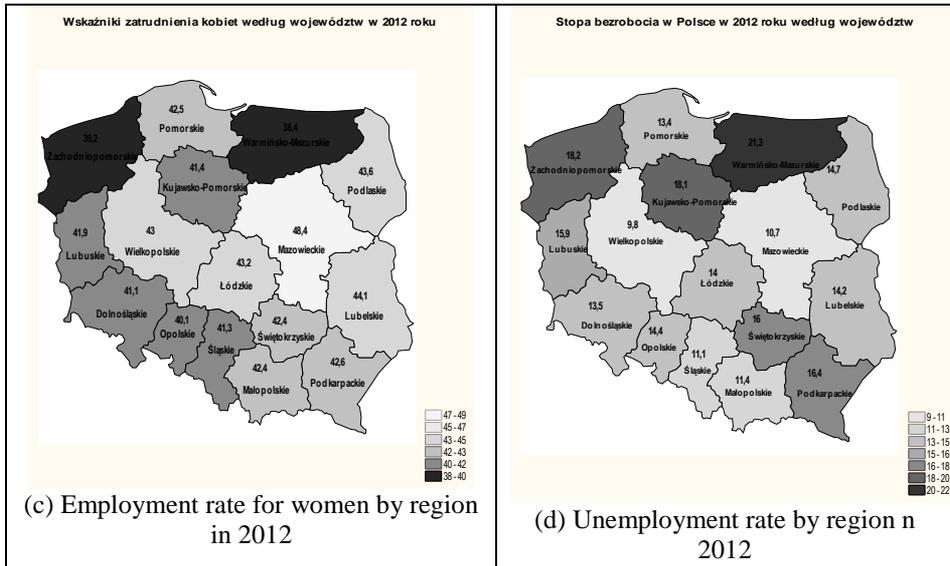

It should be noted that Poland is still a country with predominantly rural areas (93.1% of the country). In 2012, these areas had more than 15 million inhabitants (39.3% of the total population). That causes – contrary to trends in developed countries - still a high share of employment in agriculture (in 2013 in the Eastern Wall - Lubelskie - 26.5%, Podlaskie - 24.3%, Swietokrzyskie - 21.8%, Podkarpackie - 17.9%). In the eastern regions it is almost twice the national average (13.2%). Moreover, in Eastern Poland there is a large number of protected areas (almost 40% of the surface, in the case of Podkarpackie - even more than 60% of the Małopolska - more than 50%) (Boni 2007).

Thus, more than one third of the Polish population permanently living and working in rural areas and what is the problem for the Eastern Wall is the lack of large cities that constitute the metropolitan facilities for development (especially in Podkarpackie, Swietokrzyskie and Lubelskie).

Figure 8. Activity, employment and unemployment by region in Poland in 2012

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

Source: own elaboration based on regional data (BDL).

The scale of structural changes can be seen clearly on level of regional unemployment. As emphasized at the beginning - at the end of 2013 difference between the lowest (Wielkopolska with 9.6%) and the highest (Warmia-Mazury with 21.7%) unemployment rate in the Polish regions was 12.1%. Without the doubt such difference is the result of geographic location, socio-economic development, but also impact of institutions (formal and informal).

Methodology of the research

To confirm the significance of institutions' impact, I assumed that the selected quantitative indicators influence the changes in unemployment in regional labor markets. The indicators are the following:

- average real wage in the corporate sector,
- Gender gap defined as the difference in activity between men and women,
- Kaitz index calculated as the ratio of the minimum wage to the average wage.

I treat wages and Gender gap as manifestations of institutional changes in the labor market.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

In my empirical investigations I use separate panels for regions with good labor market and another for the regions with less developed labor market. The first group consists of Małopolskie, Mazowieckie, Pomorskie, Silesia and Wielkopolskie. The second group consists of Kujawsko-Pomorskie, Podkarpackie, Swietokrzyskie, Warminsko-Mazurskie and Zachodniopomorskie. I selected the regions on the base of unemployment rate in 2012.

In this section first I summarize the statistical properties of the labor market variables. To ensure stationarity the series is expressed in first differences. I present the descriptive statistics in Table 2. The mean value, median, standard deviation, skewness and kurtosis in the case of unemployment, highlights the heterogeneity of regional labor markets in Poland. The differences between regions can be seen also in the case of skewness for Gender gap.

Table 2. Descriptive Statistics of Variables Expressed in First Differences

	Unemployment		Real wage		Gender gap		Kaitz index	
	RD	RLD	RD	RLD	RD	RLD	RD	RLD
Mean	-0,055	-0,020	0,050	0,048	0,014	0,017	0,017	0,018
Median	-0,079	-0,011	0,051	0,049	0,014	0,007	0,002	0,004
Std. dev.	0,184	0,128	0,020	0,020	0,072	0,077	0,044	0,041
Skewness	0,372	0,110	-0,336	-0,573	0,616	-0,137	0,542	0,552
Kurtosis	-0,287	-0,535	-0,790	0,612	0,389	-0,324	-0,989	-0,799

RD – regions developed, RLD – regions less developed

Source: own elaboration based on BDL data.

In order to verify the research hypothesis that the institutions impact the unemployment rate I adopted two studies - Granger causality tests (Granger 1969, pp. 424-438) and impulse-response analysis . Justifying the choice of this method I should stress that both tests are well known. Moreover, the feasibility of regional research from institutional perspective is limited because of data availability. In the case of regional analysis I have to deal with a small number of observations with a large number of regions. Thus, the selection of panel methods. Furthermore, the analysis of the significance of the response function in the impulse-response method can be interpreted in a similar way to Granger causality test.

First, in the analysis of Granger causality tests I was used procedure Sargent (Sargent, 1979, pp. 8-15). In the procedure of Sargent in the first step:

$$y_t = \sum_{i=1}^k a_i y_{t-i} + \varepsilon_t. \quad (1a)$$

In the second run the regression residuals from (1a) with respect to the variable x:

$$\varepsilon_t = \sum_{i=1}^k \beta_i y_{t-i} + \sum_{i=1}^k \gamma_i x_{t-i} + \eta_t. \quad (1b)$$

Tested the hypothesis that the lack of Granger causality from x to y is:

$$H_0: \beta_1 = \beta_2 = \dots = \beta_k = 0. \quad (1c)$$

To test the hypothesis (1c) I was used likelihood ratio test.

Then I estimate a VAR model to perform the impulse-response analysis. The general form of the Vector Autoregression Model (VAR) can be written as (Kusidel 2000, pp. 15-17; Lütkepohl 2004, p. 88):

$$y_t = A_1 y_{t-1} + \dots + A_p y_{t-p} + \mu_t \quad (2)$$

where:

y_t – vector containing each of n variables of model: $y_t = (y_{1t}, \dots, y_{kt})$

A_i ($i = 1, \dots, p$) - matrices of parameters of lagged variables of vector y_t , without zero elements,

μ_t – vectors of stationary random disturbances having an independent Gaussian distribution with zero average and variance \sum_{μ} .

Results of empirical investigation

Table 3 summarizes the Granger causality tests and the signs of the response values.

Table 3. Summary of Granger causality tests and the Impulse-Response Analysis

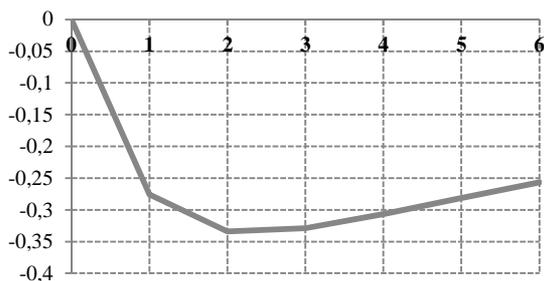

Variables	Regions with good developed labor market (RD)		Regions with less developed labor market (RLD)	
	Granger causality tests	Response	Granger causality tests	Response
Unemployment	Hypothesis rejected	negative	Hypothesis non-rejected	negative
Real wage	Hypothesis non-rejected	negative	Hypothesis rejected	positive
Gender gap	Hypothesis non-rejected	positive	Hypothesis non-rejected	positive
Kaitz index	Hypothesis non-rejected		Hypothesis non-rejected	

RD – regions developed, RLD – regions less developed

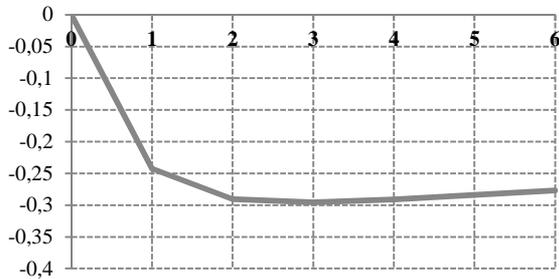

Source: own elaboration.

Summing up the results presented in Fig. 9-11, shock in real wages leads to a higher reaction of unemployment in developed regions than in less developed regions, although the results of Granger causality test indicate the significance of real wage for regions with less developed labor markets. On the other hand, the response of unemployment to shock in Gender gap is negative in developed regions and positive – in underdeveloped regions. In turn, the response of unemployment to shock in Kaitz index is positive in all analyzed panels, but reaction in developed regions is two times higher than in less developed areas. Therefore, in all tested panels we observed the positives responses of unemployment to shocks in Kaitz index, but in case of more developed regions Gender gap plays significant role, whereas, in case of less developed markets, it is real wages.

Conclusions

The efficiency and flexibility of the labor market are critical for ensuring that workers are allocated to their most effective use in the economy and provided with incentives to give their best effort in their jobs. Labor markets must therefore have the flexibility to shift workers from one economic activity to another rapidly and at low cost, and to allow for wage fluctuations without much social disruption. Efficient labor markets must also ensure clear strong incentives for employees and efforts to promote meritocracy at the workplace, and they must provide equity in the business environment between women and men (The Global Competitiveness Report 2013-2014, pp. 6-7).

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

The main goal of this paper was the description of the Polish Labor Market character and answer to the question if this market is efficient and flexible? For this answer I try to analyze how some institutions as real wage, Kaitz index and Gender gap affect the unemployment and if this impact is the same in all regions of Poland?

My estimations show that both magnitude and the direction of unemployment rate responses differ in developed and less developed regions of Poland. Changes in minimum wages are the most important factor affecting the regional labor market in Poland, but in case of more developed regions Gender gap plays significant role, whereas, in case of less developed markets, it is real wages. These conclusions seem to be particularly important from the perspective of creating recommendations for Polish Labor Market Policy.

**Welfare and Higher Education in EU Member
States – Comparative Analysis**

JEL Classification: *A11; H52; I25; I32*

Keywords: *welfare; higher education; social policy*

Abstract: This paper addresses issues related to higher education in selected EU Member States and its contribution to the creation of wealth. Special emphasis was placed on the shape of education policy in selected countries through an analysis of the main indicators characterizing the same. The paper raises a number of questions which are important from the point of view of social policy: these questions relate to the policy of higher education funding and attempts to isolate and identify the relationships between higher education funding and the situation of people with higher education on the labour market. In the first part of this paper, the author presents the phenomenon of welfare by taking into account its measurement, especially those measures that relate to education related elements. Then the author indicates the relationship between education, especially its availability, and the process of wealth creation in the economy. In the empirical part of the paper an analysis is carried out on the basis of available and comparable indicators for selected EU Member States and conclusions are drawn based on the indicators.

Introduction

Issues related to economic development and the creation of national wealth have long been the subject of scientific discourse (Smith, 2007). Wealth, which was primarily associated with material prosperity, is of in-

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

terest to researchers, especially in so far as it captures the essence of the phenomenon through its definition and appropriate measurement. Wealth creation is affected by numerous factors of a mixed character. One can look at wealth from the point of view of meeting an individual's different needs (Machaczka, 2001). In this approach, education occupies a major place because it meets the needs of the individual in the field of self-development and self-actualisation, talent development, desire to gain new skills, knowledge and understanding of the surrounding world and its underlying causes. In addition, higher education is seen as an important bargaining asset in the labour market, helping one find a well-paid and rewarding job. The massification of higher education has over the years contributed in EU countries to an increase in the number of university graduates. The market has experienced an over-representation of people boasting higher education, especially pedagogical, philological and economic (Drozdowicz-Bieć, 2014, pp.3-9). The consequences of this phenomenon can be felt in the labour market, where increasingly members of this group are faced with a lack of job offers consistent with their skills and abilities (Kocór, Strzebońska, 2014). The EU sees a steady increase in the number of unemployed people boasting higher education¹ (Dzierżek, 2014).

The paper highlights the impact of higher education in selected EU countries on the creation and multiplication of wealth. Its aim is to answer the questions posed in the paper about educational and social policies and attempt to isolate and identify the links between higher education funding and the situation of people with higher education on the labour market. The paper is structured as follows: the first part presents the phenomenon of welfare, taking into account its very measurement, especially those measures that include education related elements, and then the author presents the relationship between education, especially its availability, and the process of wealth creation in the economy. The methodological part describes hitherto research, including it describes the indicators used in the analysis of this phenomenon, methods and ways of their use. The final part presents conclusions from the analysis and indicates directions for future research.

¹ Mean value of the indicator for UE countries: 2008 -3.9%, 2009- 5.0%, 2010 -5.5%, 2011- 5.6%, 2012 - 6.2%, 2013 – 6.5%.

Welfare in economic theory

Welfare is a complex and multidimensional concept. Pertinent literature features the following alternative terms related to wealth: level of wealth, standard of living, quality of life (Kot, et al., 2004, p. 109). Level of wealth refers only to material values e.g. size of a person's property. Quality of life, in turn, is a category mostly considered from the point of view of happiness, resources and satisfaction of an individual's needs. Quality of life is a broad term spanning many complex issues. It can accommodate categories such as consumption, otherwise immeasurable individual states of a person's satisfaction, happiness deriving from consumption, use of natural resources, good health, an individual's education, prosperity in life, job satisfaction (Bywalec, 1991). According to Scanlon quality of life is the quality of the conditions in which life goes on, including protection from disease and danger, the possibility of good nutrition and education (Kot, et al., 2004, p. 111). The term "welfare" most often collocates with the "social" and "economic". "Socio-economic welfare" is another frequently used collocation. In economics, economic welfare is the utility of income and it underlies social welfare which means the state of meeting mainly health, education, leisure, place of residence and work related needs of the population. In the national economy, capital resources required for its generation, including physical, social and human capital constitute the basis for wealth creation. Economic welfare can be more broadly defined as a state consisting in the satisfaction of material and spiritual needs of the individual and society and as a trigger for a sense of self-actualisation enabling the attainment of happiness and shaping of individuals' ethical attitudes to the surrounding reality (Markiewicz, 2014, p. 7).

Social welfare has a broad meaning. This may be indicated by the broad array of its constituents, which according to E. Aksman (2010, p. 140), include: per capita GDP or GNP, level of total consumption, economic growth rate, productivity, technological progress, the level of public education, social security, population's health indicators, the degree of efficiency of administration and public safety, condition of the natural environment and the degree of development of the information society. All of the above descriptions of welfare feature education as an element leading to latter's improvement. Pertinent literature regards education as an important element of the welfare state.

The importance of education in creating prosperity is also corroborated by the fact that many of aggregate indicators measuring welfare contain

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

education related indicators. The aggregates include the HDI (Human Development Index)² which ranks countries on three levels: "long and healthy life", "knowledge" and "prosperous standard of living." HDI relies on the following indices: life expectancy, the average number of years of education received by the population aged 25 years and older, the expected number of years of education for children starting the education process, national expenditure per students in equivalent USD converted using PPPs for GDP (PPP \$)³. Another indicator used to measure economic welfare is called the Index of the Economic Aspects of Welfare EAW (Borys, 1999). It basically relies on the calculation of the level of individual consumption, additionally taking into account expenditure on education. In the Index of Sustainable Economic Welfare, among its many components is also education, including spending on education and education-related consumption. Quality of Life⁴ is a welfare measure proposed by Eurostat, which publishes separate reports on each of the following aspects of quality of life: material conditions, health, education, leisure, safety, work, family and friends. These give a comparable picture of prosperity across countries. Current welfare measurement methodology favours aggregated indicators used in ranking building. An interesting compilation of several rankings that describe welfare in most countries around the world is offered by the Legatum Institute. Its indicator of prosperity is dubbed the Legatum Prosperity Index (Legatum, 2012). This ranking was developed on the basis of the following eight aggregated indicators: economic development, opportunities for companies, quality of public administration, education, health, safety and security, personal freedom and social capital.

In all of the above indicators education features as one of their components. The level of a country's education depends on numerous factors, including the educational policy. Educational policy is regarded as one of the elements of social policy. In particular, the emphasis is on development of and access to higher education, even if only because of dependencies which are derived from the existence of people with higher education and the dynamics of economic growth (Turski, 2000, p.19). Wide access to the

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

general education smoothens up social inequalities, which is very important from the point of view of creating and multiplying wealth in society. Education forms a significant part of a person's life, indelibly shapes their personality, attitudes, skills and qualifications (Wronowska, 2012, p. 32.) Thus formed human capital is every person's unique resource which gives them a bargaining power in the labour market that distinguishes the person from other job applicants. Education plays a key role in shaping welfare, particularly in the area of meeting the needs of a higher order. Based on P. Spicker's theory of the welfare state (2005), one can point out two approaches to the creation of the theory the welfare state. The first one originates in the state's activities and programmes in the social sphere, and in the other, the welfare state is treated as an extension of mutual assistance and solidarity in the country. The author points out three basic assumptions on which the theory is based. They are as follows:

- People live within a society and have obligations and responsibilities to one another,
- Welfare is attainable and safeguarded through social activities,
- The welfare state is a means of increasing and safeguarding society' welfare.

In a narrow sense, the welfare state may refer to the state's tools to provide social services confined to health, education, housing and income maintenance (Pierson, 1998, p. 7). According to T. Marshall (1975) social policy is a government policy on the action that directly affects the well-being of citizens by providing them with services or income.

Given these above characteristics of the role of social policy in shaping welfare, one can reflect on the effects of educational policies on welfare, which is its element. The funding of higher education with public money fits in with the provision of education related social services by the state. Funding of this area with public money offers broad access for the public to such services, which demonstrates that education implements equality of opportunity. Higher education is a service craved for numerous reasons, including because of the prestige attributed to this level of education and the role it plays in the job search process. It is believed that education is an argument giving bargaining power in the labour market, in many ways allowing one to find a satisfactory job. Now, when higher education is more accessible to a wider audience than a dozen years ago, the massification of the process of acquiring knowledge at this level has its consequences, both positive and negative. The benefits include the fact that a larger percentage of the population taps into the opportunity to acquire

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

knowledge, skills and qualifications at this level of education. This is reflected in the growth of welfare in the society. Adverse effects of the massification of higher education relate primarily to developments on the labour market. The supply side predominates and the market cannot cope with it because it does not offer enough jobs consistent with acquired education and aptitude. There is stiff competition, which prolongs the process of entering the labour market and, consequently, increases demand for social policy programmes, in particular for unemployment benefits. Given the above interdependencies, i.e. on the one hand, broad access to higher education and, on the other, the impossibility of finding employment consistent with education, the paper poses the following questions: Are there any relationship, and if so, what is their nature, between higher education funding with public money and the level of unemployment among people with higher education? Can similar relationships be ascertained in all the EU countries under analysis or only in some of them? Can higher education spending be treated as a substitute for the demand for programmes implemented within the framework of social policy? Will higher education in the countries surveyed match the classical classification of welfare states as liberal, conservative and social democratic regimes⁵? (Esping-Andersen, 1990, p.44-45, Esping -Andersen, 2001).

Methodology of the research

The study covers 20 selected EU countries. The choice of countries was dictated by the availability and comparability of statistical data. Higher education in the selected group was analysed based on quantitative indicators including:

- Gross enrolment ratio in tertiary education⁶,
- Public tertiary educational expenditures as a percentage of GDP⁷
- Share of public expenditure on tertiary educational institutions (%)⁸
- Annual expenditure per students in equivalent USD converted using PPPs for GDP⁹.

⁵ Research into this area was conducted e.g. by: N. Willemse and P. de Beer, K. Czarnecki K.

⁹ Education at a Glance 2014: OECD Indicators, p. 249, http://appsso.eurostat.ec.europa.eu/nui/show.do?dataset=educ_fitotin&lang=en

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

The author also used a quantitative variable capturing the situation of people with higher education in the labour market i.e. youth unemployment by age¹⁰.

The author relies mainly on the following sources and databases: Eurostat, World Development Indicators 2014, Education at Glance 2013, Education at Glance 2014: OECD Indicators. The data is for 2011, with supplementary information from 2010 being used in just one case.

The analysis was performed relying on rankings developed on the basis of a mean value and standard deviation. This allowed for the creation of three sets ordering the examined countries into relevant groups. This in turn facilitated the inference of conclusions. In the case of indicators relating to higher education, ranks 1, 2 and 3 emerged, 1 being the lowest rank, and 3 – the highest. The higher the indicator value, the higher the rank. In the case of the labour market indicator, ranks 1, 2, 3 were also established, but here the lower the ratio, the higher the rank.

The summary table below presents the indicators and author's own calculations used in the paper.

By analysing the enrolment rate in higher education for the selected group of countries one can see that it is diverse and ranges from 55 for Slovakia to 95 for Finland, the latter being the maximum value in the sample. This indicator reveals the percentage of students at a given level of education in relation to the number of people of an age corresponding to that level of education. It shows the utilisation of the access to higher education. With regard to this indicator, the countries are arranged into three groups. Group 1, with the lowest level of the indicator, features: Slovakia, France, Germany, Hungary, Great Britain, Italy, Czech Republic, Portugal, and Latvia. Group 2 features countries with an average level of the indicator: Austria, Belgium, Denmark, Estonia, the Netherlands, Ireland, Sweden, and Poland. Group 3 consists on just three countries where the indicator is the highest – Finland, Slovenia and Spain.

* 2010 data.

The second of the indicators sheds light on the amount of higher education funding with public money in relation to GDP. This is one of the determinants of the social policy pursued in the field of the public funding of

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

education. The indicator reveals the existence of the following three groups: group 1, involving countries with the lowest level of the indicator, features: Hungary, Great Britain, Italy, Slovakia, and Slovenia. Group 2 consists of: Austria, Belgium, Czech Republic, France, Spain, Ireland, Latvia, Germany, Poland, and Portugal. Group 3 features Sweden, the Netherlands, Finland, Estonia and Denmark. As far as the level of this ratio is concerned, since 2000 it has been on a steady increase in all of the surveyed countries (Education at the Glance 2014, s. 231).

The third indicator is related to the percentage share of public funds in the financing of higher education in the overall sum of public and private funds allocated for this purpose. It seems to be the most important indicator in the set. The higher the share of state financing of higher education, the wider the audience availing itself of the service provided by the state in pursuit of social policy. This contributes to the creation of welfare, by creating an opportunity to satisfy higher order needs in the community and at the same time to enhance the quality of human capital in the economy. The legitimacy of public funding of education is related to the concept of the social investment state (Busemeyer, Marius (2013), which emphasises that activation through education of human capital and potential, which should be treated as an investment in the future constitutes the main purpose of public spending.

On the basis of this ratio the countries can be grouped as indicated below. Group 1 comprises countries with a low indicator level: Italy, Portugal, Latvia, the Netherlands, and the United Kingdom, which reveals the lowest level of the index at just 30.2%. Group 2 features Hungary, Slovakia, Poland, Germany, Spain, France, Estonia and the Czech Republic. Countries where higher education draws mainly on public funds are Austria, Belgium, Ireland, Slovenia, Sweden, Denmark and Finland, where the indicator reaches 95.9%. These countries constitute group 3.

The last of the indicators in this group shows the level of expenditure on higher education expressed as an amount per student. Countries that belong to group 1 are the Czech Republic, Estonia, Latvia, Poland, Portugal, Slovakia, Slovenia, Hungary, Great Britain, and Italy. Group 2 consists of Germany, the Netherlands, France, Belgium, and Austria. Group 3 countries are Denmark, Finland and Sweden. Statistics on Spain and Ireland were not available. In order to determine the status of implementation of education policies in these selected countries, the author created a collective ranking based on the four sub-rankings. The results are presented below.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

Table 2. Composite ranking

Rang	12	11	10	9	8	7	6	5	4
Countries	FI	DK	SE	AT, BE	SI, NL, EE	FR, IE, DE, PL	CZ	LV, PT, SK, HU	IT, UK

Source: author's own calculations based on table 1.

Based on the above, the countries can be ranked as follows. The highest possible rank is 12 and it is a rank that constitutes a benchmark of educational policy for the surveyed countries. Finland proved itself to be the benchmark and it is followed by Denmark at 11 and Sweden at 10. All three represent the social democratic regime. Countries with a ranking ranging between 9 and 5 represent the conservative regime, while countries with a ranking of 4 represent the liberal regime. This division is not final, and refers to a division proposed by Sam Yu (2012, p. 263) for other areas related to the welfare state and social policy.

Comparing the rankings in table 1 in the area of education with a ranking for the labour market (table 1) it can be said that there is no clear relationship between the phenomena discussed. However, one can see some relationships in the case of smaller groupings, notwithstanding the fact that caution should be exercised when drawing conclusions. In a few cases including Austria, Belgium, Finland, Sweden (ranked 3 and 3 respectively) a high share of public expenditure on higher education means the level of unemployment among people with higher education in the 25-29 age group is low. These cases may confirm the validity of the claim that educational policies can be substitutive in relation to social policy in these countries because a low unemployment rate is also indicative of low demand for social policy programmes. This dependence is not ascertained in Slovenia though, where high public expenditure on higher education (rank 3) is also accompanied by a high unemployment rate in the surveyed group of people (rank 1). In this case, universal access to higher education contributes to the massification of the phenomenon, whereby the number of university graduates increases and this, in turn, entails greater competition in the labour market. This phenomenon undermines the argumentation in favour of educational policy being a substitute for social policy. In the case of the Netherlands and the UK, a low share of public expenditure on higher education (rank 1) is coupled with a high unemployment rate in the age group studied. This dependence can confirm the claim that in those countries there may be

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

complementarities within social policy, between educational policy and social policy. The other surveyed countries do not permit one to draw firm conclusions. It would seem reasonable to extend the set of indicators to incorporate further indicators from the area of higher education and the labour market which would deepen the analysis.

Conclusions

The paper presents the phenomenon of welfare and ways of defining and measuring it, and underlines the importance of education in shaping it. As a result of analysis based on quantitative indicators, one can indicate the possibility of grouping countries implementing educational policy within the concept of the welfare state according to the type of their regime. One cannot clearly indicate a trend in the relationship between the level of higher education funding with public money and the size of the unemployment rate in the age group studied. The case of some countries may confirm the possibility of both substitutability and complementarities between educational and social policies in these countries. On the basis of the set of indicators used, one cannot draw clear-cut conclusions for all the countries surveyed. The research problem is more complex and the study should continue by expanding the analysis to other aspects, including aspects of the quality of social policy.

Prospects for the Development of Prosumer Energy in Poland

JEL Classification: *A11; E61; F50; H89*

Keywords: *prosumer; energy sources; renewable sources of energy; climate and energy policies*

Abstract: Renewable energy will play a key role in the transition towards a competitive, secure and sustainable energy system. In 2014 the Commission proposed an objective to increase the share of renewable energy to at least 27% of the EU's energy consumption by 2030. The European Council endorsed this target which is binding at EU level.

The Renewable Energy Directive (Directive 2009/28/EC of the European Parliament and of the Council of 23 April 2009 on the promotion of the use of energy from renewable sources and amending and subsequently repealing Directives 2001/77/EC and 2003/30/EC) was implemented in Poland on 20 February 2015 by the new renewable energy sources act.

The objective of this article is to analyse the current state of the Polish energy sector related to the prosumer energy industry. It also describes the future potential for the development of prosumer energy in Poland. The analysis was conducted in the light of the new EU climate and energy initiatives.

At the beginning, the article presents the current general state in EU's energy sector. European Union Climate and Energy Package targets up to 2050 and the state of renewable energy use gives the background to conduct an analysis of prospects for the development of prosumer energy in Poland. That is why the last part is devoted to the prosumer energy sector in Poland in the context of European Union regulations. The critical analysis of the current situation in that sector has

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

made it possible to evaluate prospects for the development of prosumer energy in Poland in the context of the recently introduced legal regulations.

Introduction

Energy is a vital factor in socio-economic development, seen by many countries as strategic to their future. It is a source of growth for competitiveness and the development of modern economies. The important role of energy stems from the fact that primary energy includes sources used by man in the process of the industrial production of electricity, heat and chemical products. The sources of energy include solid fuels, liquid fuels, nuclear fuels, and so-called renewable fuels (Niedziółka, 2010, p. 7).

Renewable energy will play a key role in the coming years in the transition towards a competitive, secure and sustainable energy system for EU as an international organization as well for the Member States. In 2014 the European Commission proposed an objective of increasing the share of renewable energy to at least 27% of the EU's energy consumption by 2030. The European Council endorsed this target which is binding at EU level.

The Renewable Energy Directive (Directive 2009/28/EC of the European Parliament and of the Council of 23 April 2009 on the promotion of the use of energy from renewable sources and amending and subsequently repealing Directives 2001/77/EC and 2003/30/EC) is one of the Climate and Energy Package document. The Directive established a common framework for the use of energy from renewable sources in order to limit greenhouse gas emissions and to promote cleaner transport. Each Member State has a target calculated according to the share of energy from renewable sources in its gross final consumption for 2020. That Directive was implemented in Poland on the 20th of February, 2015, by the new renewable energy sources act.

The objective of this article is to analyse the current state of the Polish energy sector related to the prosumer energy industry. It also describes the future potential for the development of prosumer energy in Poland. The analysis was conducted in the light of the new EU climate and energy initiatives.

Methodology of the research

This article is an attempt to find answers to the following question: - what the prospects for prosumer energy to be included in the recently intro-

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

duced legal regulations in Poland are, - whether the European Union regulations concerned Climate and Energy package will help the development of prosumer energy sector in Poland?

It seems that the development of prosumer energy in Poland is an opportunity for the Poland energy sector; however, it will depend primarily on attitude of prosumers, their energy needs and the state support for the microinstallations.

To realize the objectives of the article, the analysis is divided into four parts. At the beginning, the article presents the current general state in EU's energy sector. European Union Climate and Energy Package targets up to 2050 and the state of renewable energy use gives the background to conduct an analysis of prospects for the development of prosumer energy in Poland. That is why the last part is devoted to the prosumer energy sector in Poland.

Literature concerning European climate and energy policy is unusually extensive (see Wojtkowska-Łodej, 2003, 2014; Ważniewski, 2014; Michalski, 2013), however until now, there is a gap in the information available about the Polish energy sector related to prosumer energy (compare Nowicka-Skowron & Pachura, 2013).

The results of analysis are available for different countries and they concerned different issues. J. Rodriguez-Molina, M. Martinez-Nunez, JF. Martinez and W. Perez-Aguilar deal with emerging business models for smart grid prosumers, their strengths and weaknesses and puts forward new prosumer-oriented business models, along with their value propositions (Rodriguez-Molina & Martinez-Nunez & Martinez & Perez-Aguilar, 2014, pp. 6142-6171). GKH. Larsen, ND. van Foreest and JMA. Scherpen analysed a balance of power in a group of prosumers, based on a price mechanism (Larsen & van Foreest & Scherpen, 2013, pp. 828-836). A. Filipowska, K. Fabisz, TM. Hossa, M. Mucha and R. Hofman present a solution for managing the energy consumption and production in microgrids. They present challenges of managing such networks as well as functionalities of a system, that enables for e. g. preparation of forecasts, tracing the energy consumption or creation of recommendations for the microgrid prosumers, in order to deal with these challenges (Filipowska & Fabisz & Hossa & Mucha & Hofman, 2013, pp. 298-314).

The analysis in this article is based on the study of literature, the legal regulations and Eurostat's statistics.

Situation in the EU energy sector

As part of the regional economic integration in Europe, Member States took steps towards increasing integration of energy markets and creating common energy policy. These were accompanied by EC efforts aimed at protecting the environment, especially working against its degradation. Depending on the state of the world economy at the time, actions taken in the 70s, 80s and 90s of the previous century were varied in character. In the first decade of the 21st century a new factor in the discussions and strategies, were the attempts to link the issues of energy and climate change. This also finds expression in the policies of the Treaty on the Functioning of the European Union (Wojtkowska-Łodej, 2014, pp. 44-45). According to article 194 of the TFEU introduced in the Lisbon Treaty, „1. In the context of the establishment and functioning of the internal market and with regard for the need to preserve and improve the environment, Union policy on energy shall aim, in a spirit of solidarity between Member States, to:

- ensure the functioning of the energy market;
- ensure security of energy supply in the Union;
- promote energy efficiency and energy saving and the development of new and renewable forms of energy; and
- promote the interconnection of energy networks.” (see Zajączkowska, 2014).

These energy targets are an important factor in the EU’s Europe 2020 growth strategy (European Commission, 2010) based on the increase in competitiveness of the EU, as well as a roadmap for moving to a competitive low carbon economy in 2050 (European Commission, 2011).

In 2011 the European Union (EU-28) was the fourth biggest energy producer (6.1%), behind China (18.4%), USA (13.5%) and Russia (10%) (European Commission, 2014b, p. 10). In 2012, primary energy production in the EU stood at 794 million tons of oil equivalent and was 15% lower than in 2004. In the first decade of the 21st century the drop in energy production was gradual. An exception was the year 2009, when energy production dropped around 5% in relation to 2008 (Eurostat, 2013). This was partly the effect of the global crisis, and a drop in the demand for energy in certain Member States. An additional reason for the gradual drop in energy production could be ascribed to the industry, namely the problems faced by suppliers in the oil and gas sector.

The structure of the world’s energy sources has remained unchanged for decades. It is mainly based on the location of energy resources as well as

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

strategic political decisions, which have the biggest influence on the development of the nuclear and renewable energy sectors. In 2011, the part played by oil and oil derivatives worldwide stood at 31.3%, solid fuels 29.2%, gas 21.2%, renewable energy 12.9%, and nuclear energy 5.1%. Also noticeable is the steady increase in the consumption of oil, fossil fuels, gas and renewable sources since 1995. An exception to this is the part played by nuclear energy, which in 2011 dropped by 6% in relation to 2010 (European Commission, 2014b, p. 11).

In the European Union, the situation is slightly different. In 2012, the percentage of oil and oil derivative products used in the production of energy was 11.1%, solid fuels 20.7%, gas 16.5%, renewable sources 21.9% and nuclear energy 28.1%. Renewable energy sources and nuclear energy, therefore, constitute half of the energy production in the EU. It must be noted that 48% of the EU energy sector is dependent on fossil fuels, which produce the most CO₂ emissions, which is responsible for climate change. A major difference between the European Union and the rest of the world is the place of oil and oil derivatives (-20 p.p.), as well as nuclear energy (+23 p.p.) (European Commission, 2014b, p. 35).

Climate and Energy Package targets up to 2050

One of the key objectives of the current Climate and Energy Package is the reduction of greenhouse gas emissions by 20% compared with base year 1990. In light of the Kyoto Protocol, participating countries were responsible for the reduction of emissions of seven greenhouse gases: carbon dioxide, methane, nitrous oxide, fluorinated gases, including hydrofluorocarbons, perfluorocarbons, sulphur hexafluoride and ozone trifluoride (European Commission, 2014a, p. 3).

In January 2014, the European Commission has published the terms of the next Climate and Energy Package valid until the year 2030. Two main aims were introduced: the reduction in the emission of greenhouse gases by 40% and increasing the use of renewable energy sources to 27%, without precisely setting specific levels for each country. The debate on future EU strategy, which began in March 2014 (Green Paper to establish a 2030 framework for climate and energy policies), turned out to be difficult. Union aims for climate and energy policy until 2020 are set out clearly (known as the “20-20-20” targets or 3x20% targets). They are based on three main criteria: competitive economy, sustainable growth, and security of supply. At the start of the debate, a controversy arose on whether the European

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

Union should accept only one binding target – the reduction of greenhouse gas emissions, or whether all currently binding targets should be kept (Gawlikowska-Fyk, 2014, p. 1).

In October 2104 Union leaders gathered for the Brussels summit agreed that by 2030 the EU will reduce CO₂ emissions by at least 40 per cent compared with 1990. Additionally, under a new Climate and Energy Package it was established that free allowances for emissions will be applicable after 2020 and not only until 2019 as was established previously. Efforts will be made in Brussels concerning legislative solutions which will ensure this goal is achieved. The European Union will therefore introduce its obligations in the first quarter of 2015.

For 2050, EU has endorsed the objective of reducing Europe's greenhouse gas emissions by 80-95% compared to 1990 levels as part of efforts by developed countries as a group to reduce their emissions by a similar degree set for 2020 year.

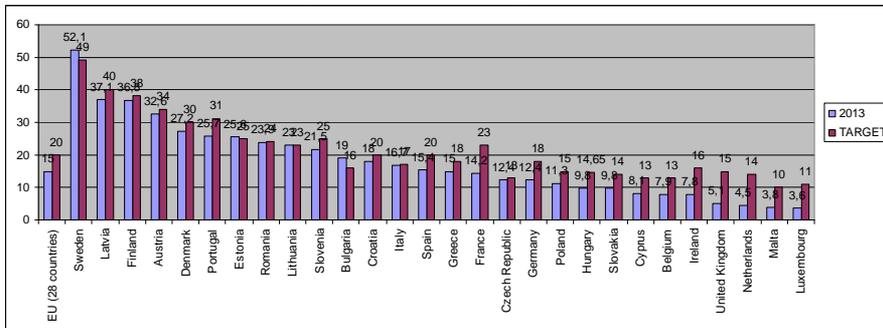

Renewable Energy Use

In the currently applicable 3x20% targets, the increased use of renewable energy sources has been set to at least 20% of overall energy production (in the electricity, heating and transport sectors), with 10% of biofuels to be used in transport, relative to 2006. The real capabilities of Member States were, however, taken into account, hence the application of the category of national plans, in which Member States set their own indication levels towards which they are striving. The ranges vary substantially across the Union.

Figure 1 shows the share of renewable energy sources in the final total energy consumption of EU Member States in 2012 against national plans for the year 2020.

Analysis of the data presented in the figure above, leads to the conclusion that quite early on, the plan to increase the usage of renewable energy has been successfully implemented in Sweden, Estonia, Lithuania and Bulgaria, with Sweden exceeding the 50% mark. The furthest from meeting their national criteria were Great Britain (9.9 p.p.), Netherlands (9.5 p.p.), France (8.8 p.p.) and Ireland (8.2 p.p.). Poland has a chance of meeting its target of 15%, because it achieved a level of 11,3% as early as 2013 (Eurostat, 2013).

Figure 1. Share of renewable energy in gross final energy consumption of EU Member States in 2013 compared with national plans for the year 2020 (in %)

Source: own calculations based on Eurostat (2013). Retrived from : http://ec.europa.eu/eurostat/tgm/table.do?tab=table&init=1&language=en&pcode=t2020_31&plugin=1 (26.01.2015).

From the above figure 1 it can be seen that the highest target in the usage of renewable energy as an overall part of country energy mix was set by Sweden at 49%, with the lowest being Malta at 10%.

Situation in Poland's energy sector

The energy situation in Poland seems challenging. Most electrical power and heating stations have old power units that should be taken off the grid in the next few years due to wear and age. Even if a decision is made to build a nuclear power station, it will only meet a small portion of the country's energy needs. Also, shale gas extraction will not be ready in the nearest future. Therefore every decision concerning the country's energy policy will play a vital role in securing Poland's energy as well as diversifying energy sources (Grzegorzczuk, 2014, p. 208). Creating small microgrids systems might become the solution that will help solve Poland's two basic energy problems: the necessity to modernize coal power stations; and support for building nuclear power stations. The simultaneous passing of legislation concerning renewable energy sources will meet European Union climate and energy policy targets while also fulfilling Poland's international responsibilities.

After a few years of work on the project, on 20 February 2015 the Sejm passed legislation concerning renewable energy sources (Ustawa o odnawialnych źródłach energii, 2015). The renewable energy resources act will come into force after 30 days and regulations concern an auction sys-

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

tem and feed-in tariffs on 1 January 2016. The new laws introduced new principles that support energy production from renewable energy sources. It is the sign of the Renewable Energy Directive implementation.

One of the fundamental changes to the currently applicable laws supporting renewable energy sources is the replacement of the guarantee green certificates with an auction system. The government is to decide how much renewable energy is needed, taking into account EU climate policy. Auctions are then prepared in which the lowest bidder wins. In exchange they are issued a guarantee of support for 15 years. Auctions will be separate for different technologies, as well as large and small installations. The support of renewable sources will be passed onto consumers, who will incur an additional renewable energy fee. In its first year this cost will amount to PLN 2.27 per megawatt-hour of electricity.

The legislation also foresees the requirement to buy energy and feed-in tariffs for the resale of electrical energy by prosumers. A constant price of PLN 0.75 per kilowatt-hour has been set for 15 years from sources up to 3 kW and for energy originating from hydroelectric, wind and solar sources. A constant price will also be applicable for sources between 3 kW and 10 kW – PLN 0.70 for one kilowatt-hour of energy from agricultural biogas, PLN 0.55 for biogas from storage, and PLN 0.45 from sewage works. A constant price of PLN 0.65 will apply for a kilowatt-hour of energy for hydroelectric, wind and solar energy. For these sources there is also an obligation to purchase for 15 years from when the installation goes into use.

Feed-in tariffs for home micro-installations of renewable energy sources is a chance for many people to lower their energy bills. This solution could in time improve the situation for all citizens, because it provides access to the energy production market even for the smallest home renewable energy source and lowers the cost of investment in distribution networks, which would be spread amongst all energy users. The government's earlier proposal would have meant that only wealthy people would be able to afford investing in renewable energy sources. Feed-in tariffs have leveled the opportunity of buying micro-installations, as well as limiting costs and distributing them in a fairer way. This change is important, but minor from the overall perspective of the whole renewable energy sector, as it only amounts to 1% of the whole electrical energy market. It is therefore not enough to solve the problems of renewable energy in Poland.

A valuation of the effects of regulation estimates the cost of the future legislation at ca. PLN 4 bn per annum. For prosumer installations, i.e. those up to 40 kW, no concession or formation of a business will be required. It

will also be possible to sell surplus energy back to the grid (compare Cyglicki, 2014).

Conclusions

Two of three treaties calling the European Communities into existence dealt with the energy sector. Over the last few decades the EU has accepted legislation amounting to numerous Energy, and later Climate and Energy Packages. However, specific regulations regarding energy were not written into primary law of the EU. The situation changed with the acceptance of the Lisbon Treaty. By the authority of this treaty, articles concerning Energy were introduced into the Treaty and the functioning of the European Union, whereby energy policy gained treaty backing. Next, these resolutions were included in the Strategy for smart, sustainable and inclusive growth, and in the Roadmap for moving to a competitive low carbon economy in 2050. These documents show the direction the EU will take in the next 30 years, which can be described as green growth and stable development. It should also be highlighted that the acceptance at the Brussels summit in October 2014 of goals regarding the reduction of CO₂ emissions by at least 40 percent by 2030 relative to 1990 requires further detailed legislative work, which will ensure reaching the target. Work on these will take place in parallel with the international agreement which will be reached at the COP20 summit in Paris in 2015 and will replace the currently used Kyoto protocol of 1997.

The dynamics of reform and real change in the energy sector in Poland differ from those found in the energy sectors of other EU countries and are mainly the result of historical factors. While preparing the framework for the next Climate and Energy Package, the European Commission should consider the specifics of the energy sector in each East-Central Europe country, including Poland. Failing that, the meeting of the interests of individual countries will become more important than the implementation of the common Climate and Energy Policy. The European Union should therefore increase the size of the European funds assigned to infrastructure investments in the energy sector of countries in East-Central Europe.

The energy-mix options available in each Member State are varied. Member States can focus on developing their own choice of energy sources, but it is also necessary to include European targets, especially renewable energy sources.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

It seems that, in light of the experiments conducted in different countries, prosumer energy presents an opportunity for the Polish energy market, because it could lower the cost of electrical energy and create new sector jobs. There are analysis that in 2020 aggregate heat and electricity power from microinstalations based on renewable energy sources will achieve 38,5 TWh (for electrical energy 2,9 TWh) and the number of prosumers will exceed 2,5 million in Poland (Instytut Energetyki Odnawialnej, 2013).

Moreover, the growth of prosumer energy supplies could have a positive impact on meeting the criteria of the Climate and Energy Package, specifically the 20% reduction of CO₂ emissions by 2020.

However, the final word on growth will belong to the prosumers, their local conditions, as well as individual preference and choice.

A Paradox of Reforming Pensions in Poland

JEL Classification: *P16; B52*

Keywords: *funded pensions; pension reform; public finance*

Abstract: Recent years see intense reforming of funded pensions sub-system in Poland. Actually, what are policy objectives like at which change in design introduced in 2013 (mandatory funding) and projected in 2014 (voluntary funding) is oriented? The article briefly reports what was contemporary re-designing of the pension system at different stages about and reconstructs objectives of reforming at each stage. It finds that interlocking streams of change aimed at two goals in fact which are i) relief to public finance ii) expanding pension funding by financial intermediaries. It argues that the two are in contradiction to each other, and this makes a paradox of pension reforming. The review of 2013- and 2014- design, unexpectedly enough, results in conclusion that at present reforming is focused on pension funding revitalization which may cause a recurring distress to public finance. Thus, the article identifies one of dilemmas of institutional-order development in Poland which can be probably also experienced in other countries where pension funding has been introduced.

Introduction

Funded pensions introduced in Poland in 1999 appear to be an issue which is intensively debated from time to time. In January 2015 the theme returned with the project of reforming pension funds created on voluntary basis. December 2013 saw relevant change in rules that govern mandatory funding. Mandatory funding was scaled down while voluntary funding can

18-19 June 2015, Economics and Finance**

see „pumping-in” both of public money and members. Understanding of the process at stake is in no proportion to the temperature of publicity provided. Are the privately managed tiers of pension system in Poland in demise or on rise? This is an attempt to understand reforming at recent stage thanks to taking broader perspective of Polish pension reforms.

The paper arrives at conclusion that subsequent waves of reforms demonstrated immanent flaw which are contradictory goals of the publicly- and privately managed tiers of the system. This paradox of the pension reforms has persisted since 1999 up to present, and seems to explain the policy inconsistency identified above.

Methodology of the research

The analysis of pension engineering and economic reasons for change is organized in historical order. The next section reports in brief what was contemporary re-designing of pension systems at different stages about. The major differences in shape divide the history of pension systems into three periods: pre-reform, the 1990s and beyond as well as 2008 and beyond. This calendar organizes contents of the major section that follows. Objectives of reforming at each stage are derived from announcements of officials who are either politicians or policy-makers or experts. The discussion differentiates between explicit and implicit goals, pointing apart of official announcements also to actual outcomes.

Changing design: the stages¹

The most widespread scheme for financing pensions is insurance where a benefit is conditioned on contribution. Apparently, universal old-age insurance is a very special branch of finance as far as its original social mission concerned. The traditional core idea of designing old-age insurance has been safety which is provided by an income (pension) to be paid to a person when in the retirement age; income high enough to protect from living in poverty has been at heart of the mission. The first wave of pension

¹ This section and the next section to some extent draw from my article: Institutional interests and institutional change. Poland on the second wave of pension reforms, *Equilibrium* 2014 No 4. However, their contents have been considerably extended by developments in Poland of the last quarter of 2014 with the scope broadened by funding on voluntary basis. Reforms in full-fledged market economies are left beyond the scope of this paper. For details and variety in design see the article mentioned.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

reforms in the 1990s and early 2000s eroded this founding principle in most countries, Poland included.

Originally, the initiative of old-age insurance developed in the private sector, and appeared in form of local mutual insurance (so called social insurance companies in Poland; Bratkowski, 2014). Then it was captured by the state. Under welfare capitalism universal mandatory pension systems became common; pension-system design in Poland after WWII got the same character. Governments mandated individual employees to participate in the pension systems which were normally publicly managed. Compulsion was considered to generate an implicit government guarantee of decent retirement benefits (minimum pension guarantee). "Decent" refers to levels meeting needs which are believed to be basic for living in the society (so called social minimum). This was a broad meaning of Defined Benefit (DB) formula relating benefit and contribution. Basically, public insurers were believed to afford benefits adequate to social minimum at least due to another founding pillar of pre-reform pension system which was financing on PAYG basis since this system of financing allowed for income redistribution.

At turn of the millenium as observed in Poland's country category the paradigm of pension systems was changed (Sarfati & Ghellab, 2012). By saying this we mean such basic features like ownership characteristics of major fund-managing agents, way of making records², and most of all contribution-to-benefit formula and system of financing.

Firstly, the basic relation between contribution and benefit was changed, namely Defined Benefit (DB) formula was replaced with a Defined Contribution (DC) formula in the system as a whole. Thus guarantees of social minimum were withdrawn from the pension industry and the risk of old-age poverty was shifted from managing agent to contributor with extremely low retirement benefit eventually being supplied up to minimal level from social aid resources. According to DB formula benefit may be based on the worker's final wage and length of service, however, it does not depend on the amount of assets accumulated in the person's name; instead, funds are adjusted to meet obligations; thus the risk of varying rates of return to pension assets falls on the sponsor. In traditional system the fund-managing public agency was backed by the state budget who was the sponsor. Under DC formula, on contrary, the benefit is determined by the amount of capital paid in toward a person's pension. A pure DC plan adjusts obligations to

² In Poland individual accounting of contributions was introduced in place of a central trust fund.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

match available funds; thus this is individual contributor who faces the portfolio risk (Barr & Diamond, 2008a).

Secondly, with respect to financing the PAYG system was supplemented with capital funded pension schemes. Pay-as-you-go (PAYG) pensions are paid out of current revenue that comes, basically, from contributions to the system made by the actually employed (the prospective pensioners) and/or their employers. Funded pensions use an accumulated fund built from contributions by or on behalf of its members which is invested in securities. In this tier of the system pension benefits are paid basically from paid in capital and investment outcomes, and no redistribution between current contributors and current beneficiaries takes place. Thus a multi-tier system was created. The law of 1997 allowed for pension savings to be channeled to the licensed agents for both voluntary and mandatory funded schemes to be created. The outcome of the reform in the shape of three "pillars" is presented in table1.

Around 1999 the reform engineering split the traditional pension system into publicly- and privately managed pillars, run by ZUS as well as by the PTEs and TFIs respectively. The the TFIs and the PTEs are private companies founded mainly by banks and some insurers. Thus the state has invited private firms into the area which traditionally was a domain of state compulsion and was managed by a public agency. Mandatory contributions raised by ZUS have since then been divided into funds run by ZUS and run by PTEs while funds run by TFIs enjoyed fiscal support in the shape of tax relief.

Years 2008 and beyond have seen intense reforming of privately managed sub-system of funded pensions. These developments can be regarded a new stage in contrast to reforming and splitting traditional PAYG system before. After 2008 numerous regulations referring to OFEs (II pillar) and new propositions referring to voluntary pension funds (III pillar) appeared³.

³ Historical report requires mentioning a relevant change introduced in the system as a whole in 2012 that is the shift of statutory retirement age on to 67 to be gradually completed in 2020 with regard to males and in 2040 with regard to females.

* The share was reduced to 3,5 per cent in 2011 r. and to 2,92% in 2013.

** Fully-funded pensions pay all of benefits from accumulated funds. Funded pensions use an accumulated fund built from contributions by or on behalf of its members (Barr, Diamond 2009).

***According to the law of 2013 ZUS is in charge of paying out the annuities from both pillars.

Source : developed by the author.

As far as mandatory pension funds concerned, the government scaled them down gradually since 2009⁴ with the law of December 2013 as a breakthrough. Since 1999 the mandatory contribution used to be automatically divided between I pillar and II pillar (see table 1) and thus in effect of state compulsion open pension funds (the OFEs) were created. Since 2013 the PTEs that is profit-making companies specialized in managing OFEs are sure of steady inflow of contributions no more. The new law opened opportunity for members to express their will in multi-years intervals. In defined periods they are allowed to declare whether they are going to stay in the OFE tier vel II pillar. In the event no declaration of insured person has been made his or her contribution remains under management of ZUS, undivided. The same procedure refers to persons who are just about to enter the labour market. In the event they have not explicitly chosen otherwise their contribution will be administered by ZUS since the random selection which used to distribute such cases among the OFEs was cancelled (Ustawa, 2013). The first such opportunity with the deadline for decision-making

⁴ There were reductions in fees in 2009 as well as in portions contributed to the OFEs in 2011.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

at end of July 2014 resulted in number of OFEs' members having shrunk from ca. 16 million to 2.5 million.

In result of the 2013 reform OFEs found themselves scaled down not in terms of number of contributors alone but also in terms of their share in the mandatory pension saving. Those members who still wish to contribute to an open pension fund can declare only 2,92 of their wage to be transferred to the fund. Thus, both number of contributors and value of transfers of individual contributions shrunk. Consequently, this means dramatic down-scaling of PTEs' incomes for which the value of funds accumulated is critical. According to OFE-tier regulations PTEs benefit from "transaction cost-covering" fees charged as percentage of contribution to OFE and from provisions charged as percentage of funds accumulated. The former was cut by half and reduced to 1,75 p.p., and revenues due to the latter fall automatically following the funds.

Independently, that is before the dramatic change in number of contributors could be included into calculus, in early February 2014 the OFEs found assets on their members' accounts reduced by 51.5 per cent due to obligatory transfer of treasury bonds and publicly guaranteed securities from their portfolios to a special account under ZUS management. The rest of accumulated assets, that is mainly shares remained with OFEs no matter whether pension savers declared "stay" either "exit", and is bound to new investment limits. This and a couple of other changes brought into mandatory pension funding by 2013 law will appear in commentary later on. What should be mentioned here is that these assets are going to leak out from the OFEs gradually due to special rule concerning those members who are close to the retirement age. Once a fund-managing company is informed by ZUS that a given OFE-member is aged 10 years below due retirement age it is obliged to default systematically each month a due part of accounting units on his or her individual account while these liabilities appear on his or her individual account in ZUS (Ustawa, 2013).

Year 2014 witnessed a new offensive with regard to voluntary pension funds. At that time at request of President's Bureau a project was prepared by the Association of Polish Economists and was officially presented in January 2015. Its general idea seems to be accommodating voluntary schemes by transfers of public money, as well as providing new members due to introducing by the state a peculiar automatism beside individual choice. The expertise suggests three options which are tax relief for the IKZE- and IKE-members, a quota of public money for prospective contributors, and universal automatic participation in PPE with opportunity to opt-

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

out. The first and second option are so designed as to expand TFI customers group including persons earning wages below the average in particular. This is to be achieved thanks to giving-up a part of budget revenues due to personal income tax (PIT) and/or via public donations to individual accounts run by the TFIs. The costs for state budget are estimated in the report at milliards of zlotys, varying from 2.2 milliard to 6.2 milliard per year for a single case (Dodatkowy...2014).

The third option of pension saving with the TFIs are employers pension schemes (PPEs) already in operation, however, with the reversed act of will of the insured persons as a novelty. Presently, a declaration of an employee is necessary to participate in the scheme. According to the new design, a declaration of an employee would be necessary in aim to opt out since under regulations proposed each employee and each newly-employed person would automatically become a member of a PPE chosen by the company. The project is a promise of rapid increase in number of contributors for TFIs and of an almost costless arrangement for employers. The latter is based on the idea that employer's part of contribution could be paid from company's social funds (ZFSS). The experts estimate these funds at ca 2 milliard zloty per year (Dodatkowy...2014). Thus, this option instead of public money makes company's social funds engaged and transferred in part to pension funds.

In sum year 2014 saw dramatic cuts in funds transferred to II pillar by public agency (ZUS) on the one hand and projects to transfer considerable amounts of public and/or social money to III pillar on the other hand. This policy inconsistency needs deliberation. For better understanding of the processes observed we must take perspective which is broader than pension engineering, and we have to trace objectives of reforming pensions which definitely can not be reduced to the traditional social mission.

Doing so, we will draw from/take advantage of this piece of analysis. This section has shown that dynamics of reforms in Poland can be measured by stages as reported above.

The starting point is the pre-reform shape of the pension system. Mandatory pension saving was managed exclusively by public agency then with implicit state guarantees of retirement benefits adequate to social minimum.

Years 1999 and beyond saw the architecture of pension system profoundly transformed due to shifting the risk of old-age poverty from managing agency to contributors in the system as a whole, with privately managed pension funding having been introduced.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

The 2008 aftermath, and 2103 law in particular, brought relevant reforms of privately managed pension funding with mandatory pension saving getting scaled down and with voluntary pension saving becoming eventually accommodated by transfers of public money and/or provided by new members to extraordinary extent.

The search for explicit and implicit objectives of change will be organized in accordance to these stages.

Changing design: objectives and outcomes

Contemporary rhetoric concerning goals of pension reform says about improved social safety, fiscal balance and solvency of the pension system, individualism and privatisation. Such rationalization is still present in political and economic debates. Actually, historical approach to dynamics of reforms reveals a departure from functions of mostly social and political nature to accounting and other issues related with private and/or public finance.

Pre-reform

Pension system as designed in Poland at pre-1999 stage can be said to have had counter-poverty and counter-social-exclusion functions. According to Barr and Diamond (2014, p.31) there are two basic functions of pension system. Pension funds are designed to "smooth down" the income along lifetime of an individual that is while employed and while retired. In social dimension pension-system function is also to redistribute income and wealth in aim to contain poverty of contributors after retirement. Obviously enough these functions declared by Barr and Diamond as their focus aim at economic safety and material-needs satisfaction of the pensioners. However, they are by no means entirely economic objectives but rather social and/or political ones. National pension systems had been designed with regard to improving social equity and, thus, preserving social peace.

The latter statements are supported by Polish pre-reform evidence. The heritage of the previous social and economic order was the pension system where one of the construction pillars was PAYG financing and income redistribution, and another was DB formula with state implicit guarantees regarding social minimum. The opening years of systemic transformation in Poland saw social peace broken and pension system used as a device of cooling down social riots. Those appeared mostly as going on strikes in

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

great state-owned enterprises where both real wages and jobs seemed to be affected by macroeconomic austerity and the set-off of privatisation. As a matter of fact, unemployment rate was on dramatic rise, and in aim to reduce social and political costs of mass unemployment early retirement was allowed as well as invalid rents became relatively easy to acquire. Thus, increased outlays from the pension system replaced to much extent social aid, and a number of people acquired status of early pensioners and official invalids instead of being unemployed. In the 1990s the publicly managed system of old-age insurance was used more apparently than ever to serve social and political goals⁵.

This early re-forming of the system, however, increased implicit pension debt to unprecedented extent⁶. One decade later at the turn of millennium pensions and rents were paid out to nearly 25 per cent of inhabitants, while people in retirement age constituted only 13 per cent (Zieliński 2003). Increased outlays contributed to public finance instability, current illiquidity and implicit insolvency of the pension system. At the turn of 1999 and 2000 statistics for Poland revealed significant pension spending and record implicit pension debt (Impavido, Tower, 2009, p.41, table 8). The latter is meant by the IMF as a rough indicator of the accrued value of the pension system liabilities where the government needs to bail out the pension system. According to the IMF among thirty five low and middle income countries Poland had 3-rd largest pension spending as share of GDP and 5-th largest implicit pension debt as share of GDP with public debt at that time being though relatively moderate (the 16-th position).

1999 and beyond

Improving the deficit of the public pension (and implicit pension debt) became an urgent objective of the 1999 reform. The related issue was constraining increase in public debt. Although public debt was rather moderate when 1999 reform gained shape it could be easily predicted to be on rise once the public pension was in deficit. As already said, DB means funds are adjusted to meet obligations, and when public pension system is unable to

⁵ Moreover, some professions of political relevance like police, army, judges, clergymen have enjoyed noncontributory universal pension financed from the governmental budget.

⁶ Other reason of implicit pension debt more widely publicized than that one was demographic change. While considering this argument to be rather controversial when applied to Poland we deliberately skip the discussion for the sake of maintaining line of reasoned discussion.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

make this adjustment then implicit benefit guarantees make the state to become the sponsor. Thus outlays from the state budget on behalf of public pension appear and, eventually, budget deficits increase. Under such circumstances, shifting from DB to DC means a relief to the budget. With the portfolio risk shifted to individual contributor there was a relief to the sponsor. Therefore, the change in the formula in 1999 should be seen as aimed indirectly at prospective problem of public debt.

Improving implicit pension debt can be regarded to be a goal while constraining rates of replacement to be an immediate objective. According to Nicolas Barr and Peter Diamond if a public pension is running deficit that is regarded as unsustainable, the only solution is to make it sustainable by increasing contributions, reducing benefits, or both (Barr & Diamond, 2008b). In Poland the relative benefit was radically reduced which means plummeting predicted pension benefit as related to average or last wage (Wiktorow 2008, p.36, table 3). In pension-engineering slang this index is called a rate of replacement. Diminishing values of the index meant roughly that planned outflows from the system were to be lower in relation to inflows to the system, and this was the way of constraining rise in the implicit pension debt⁷. One of the authors of the reform claimed in 2002: "The reform apparently was just aimed at diminishing this index. In the aging society this is requirement of systemic solvency." (Hausner 2002).

Thus the fundamental change in the contribution-to-benefit formula appears to serve a relief in public finance or, to be more precise, in general-government finance⁸. This means that accounting and financial goals won priority before social ones. The same observation can be applied as far as another fundamental change in design concerned which was emergence of pension funding. Investing part of savings accumulated in pension funds instead of paying them out immediately for pensions and current consumption as under PAYG actually means introducing financial logic into the system. Pension funding, however, was never chosen to be presented to the public in that direct way.

Foreseen constraint in rates of replacement needed to be somehow cushioned with regard to the public. The official concept of "security due to diversity" which was originally elaborated by UNFE (2000) said that a multi-tier system is to create more security for prospective pensioners. In-

⁷ Another way of reducing outflows from the system and postponing them as well was shifting a retirement age. It became politically feasible, however, only in 2012.

⁸ General government contains, beside the governmental budget also local budgets and other (extra-budgetary) public funds.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

cluding pension funding into the reform seemed to be of help along with the following rationale attached. Funded pension schemes will possibly increase their part of pension income, improve the sum of benefits originating from different pillars and effectively constrain a further risk of old-age poverty. This reasoning makes a multi-pillar approach for the pension system attractive thanks to suggestion of improving rather than deteriorating outcome of the system as a whole. Another argument extensively used said that funding in the pension system made pensions free from political abuse ("political risk"), to some extent at least.

Rhetoric pointing to social function of institutional design with pension funds constituting additional pillars provided a smokescreen. The point is that pension funding, and OFE in particular, was introduced not to secure future pensions but to invest pension savings (Szumlicz, 2002). As far as mandatory pension funding concerned expertise for decision-makers exposed saving-and-investment issues. It said about "profit-oriented investment regarding acceptable risk" being rather enigmatic on possible increase in retirement benefits (Grabczan, 1998). The supporters of introducing the OFEs added "fairness" of the deal (Góra, 2002) which is, however, a double-edged sword with respect to benefits since capital pension funding is subject evenly to losses and gains under *bessa* and *hossa*, and no insurance for mandated contributors against the loss of assets was introduced.

As a matter of fact, new pension system architecture introduced financial-market logic to where principle of social insurance had ruled. Financial markets development can be said another genuine goal of the 1999 reform. Pension funds channel domestic savings to financial operations being a vehicle of exchange of their contributors' savings into securities, so their rise meant increase in turnover of bonds and shares by definition. More, new opportunities of making profits on financial-assets turnover attracted foreign capital. We find expansion of pension funding by financial intermediaries and, consequently, financial markets development as another major goal beside relief to public finance.

To sum up, of the two major changes which the reform brought, the shift from DB to DC formula was a rather direct device of alleviating pressure on the pension and budget deficits. The shift from DB to DC means as already said that funds which can be found at the core of contemporary pension systems are to be adjusted to meet obligations no more. Thus public pension deficit can be constrained and subsidies from the state budget can be diminished. This is the non-questioned financial aspect associated with the Polish reform that is ultimately beneficial for public finance

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

(Łaski, 2010). The move to mandatory funding, however, had immediate adverse effect on both public pension and budget deficits. The price to be paid was the explicit budget gap due to transferring to OFEs "their" portion of contribution which increased deficits of the publicly managed pension fund (FUS) and enforced donations from the government budget thus contributing to fiscal deficits. Three concepts at least served to cut controversy about the move to mandatory funding from fiscal point of view. They were privatization fund as a cushion; supposition that the OFEs would be included into general government, with the EU approval; the premise that developed financial markets are good for economic growth. From retrospect all of them turned out to be weakly-founded. Fiscal cost of voluntary funding, mostly due to tax relief, can be neglected as far as now because of marginal size of this tier, however, it is potentially detrimental along with increasing both the size of the pillar and the scope of privileges of this tier.

Introducing funding into Polish pension system, however detrimental from fiscal perspective, was relevant for financial markets development. A part of mandatory pension savings is transferred out beyond the PAYG system and is bound to market rules. Transferring a portion of pension savings, voluntary savings included, to financial markets results in increases in securities turnover and means development of earning opportunities there. As a matter of fact the OFE project and introducing voluntary pension funding as well were an invitation for foreign capital groups to bring equity and go into business in Poland in the shape of the PTEs or TFIs. In 1999 foreign investors held directly or indirectly 75 per cent of the PTEs assets (Rymsza, 2002, p.265). The biggest open pension funds got under management of international banks and insurers or their subsidiaries, with ING Nationale-Nederlanden Polska, Unicredit and AIG among them. Under transition to full-fledged market economy development of financial markets as well as rules inviting for foreign capital inflows apparently gained in prominence. At turn of the millenium particularly OFEs could have been perceived as a helpful institutional device with these respects. However, such speculations if in place turned out to be exaggerated, and explicit public debt issue became a first-hand reason for 2013 policy turnabout.

2013 aftermath

Transfers of percentage of mandatory contributions to OFEs mentioned before which had added to fiscal deficits and, consequently, to public debt appear as the main reason of the reversal. According to the stance, con-

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

firmed definitely by Eurostat in 2004, OFEs can not be regarded as an institution of general government sector. If so, transfers made by ZUS to OFEs count as liabilities of the sector and add to public debt as related to GDP a couple of percentage points. "After having broken the EU budget deficit bench-mark, with the burden of public debt approaching another EU limit the government represented by minister of finance John Vincent Rostowski said the cost of maintaining OFEs in terms of public debt was too high". Thus, even more obviously than in the late 1990s the reform was induced by General Government accounting. The law of 2013 explicitly aimed at constraint of costs which the pension system had induced to the governmental budget and predicted numerous economic benefits due to that action (Uzasadnienie... , 2013, p.61-62).

However, one can argue that in spite of determination in following the fiscal line even after 2013 some other regulations were oriented on expansion of private pension funding. There are two arguments at least that seem to support such implicit goal. First, OFEs have never been eradicated and we are going to show now that they can still prosper fairly well after 2013. Second, we are just observing changing attitude on behalf of voluntary funded pillar. The ideas which founded the PTEs' business seem to find continuation in projects concerning the TFIs.

The reform of 2013 keeps mandatory pension funding still active. As already said, it has opened opportunity to shift membership out of the OFE tier and reduced significantly assets at OFEs' disposal. Thus, logics of doing business by the PTEs (and probably, their involvement as well) must have been changed. They are to rely less on amount of capital and due fees and they will probably strive for rewards based on the velocity of capital turnover. This supposition seems to be in accord with some other regulations introduced by the law of 2013. Fees charged as percentage of contribution were radically constrained and thus the due revenues were reduced⁹. However, since 2014, structural limits concerning OFEs' assets have been abolished and the maximum share of assets denominated in foreign currencies was impressingly increased from 1.27 per cent to 30 per cent (Uzasadnienie ..., 2013). This opens space for relatively risky operations on shares and in foreign stock exchanges in search of higher yields. The more so, since each PTE is free to point reference indices of their own to be used as a bench-mark to the rates of return of "their" OFE (Rutecka, 2014). With

⁹ As far as other factors of calculus concerned the maximum management commission charged by the PTEs on assets remained unchanged and fees paid due to transfers made by ZUS were cut down to 0,4%.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

equities share in assets increased up to 85 per cent mandatory pension funds are likely to turn into aggressive investment funds. The OFEs saw their assets, both those accumulated and those predicted, significantly reduced and the PTEs probably have to accept their record rates of return plummeting (Capital Strategy 2013). Nevertheless, simultaneously new opportunities of doing business in the mandatory funding tier appeared. Therefore the reform must be seen as a struggle to constrain public deficits and debts rather than a battle against privileges in the mandatory privately managed tier. The OFEs have been not eradicated, and fund-managing companies have still a chance to be handsomely rewarded, becoming far more aggressive investors in capital markets.

As far as pension schemes managed by the TFIs concerned an idea of universality is on top as expressed explicitly in the motto of the 2014 project and repeated in the declared objectives of three proposals discussed above in section 2 of this article. Pension funding in III pillar is meant to acquire a universal dimension in the sense of mass membership, the pre-2013 II pillar alike. Respectively, thanks to tax relief "as many persons as possible" from low-income groups are to be included into the IKE and IKZE schemes which are to be attractive for both full-time workers and self-employed persons as well (Dodatkowy....2014, p. 57). This is also the target group of the second proposal referring to public donation for individuals as a "carrot" which would result in "universal individual extra old-age insurance" (Dodatkowy....2014, p.65). Similarly, the last proposal aims at "universal participation in employers' schemes" (Dodatkowy....2014, p.70). This option is most likely to result in mass membership due to automatic inclusion of persons employed in the public and private sectors. This "automatism" would be achieved thanks to respective change in law. Therefore it can be regarded as a "stick" or a discreet introduction of state compulsion into III pillar (Oreziak, 2015). Opting-out which would be allowed in strictly defined periods of time seems to be far not enough to call this form of insurance a voluntary one. The explicit goal of the projected reform is to make membership to pension funding run by the TFIs as large as once the one to pension funding run by the OFEs was; the implicit intermediate objective with regard to this option is to change its voluntary nature into mandatory saving in fact thus following the OFE pattern again.

To sum up, however the claim regarding expansion of privately managed pension funding may appear paradoxical in the face of down-scaling the OFEs under law of 2013 the PTEs may become more aggressive investors in capital markets, and thus they are given new opportunities of doing

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

business and money. More, the first year under new law concerning OFEs saw change in thinking in favor of funds managed by TFIs. The project of 2014 just discussed may be regarded as an attempt to compensate the dramatic down-scaling of mandatory pension funds with channeling savings to voluntary pension funds even if it was to be made with use of "stick".

Putting findings in this section together:

- The pre-reform pension system had been oriented at functions of mostly social and political nature.
- The 1999 reform initiated a departure to accounting issues related with private and/or public finance. The socially-sensitive pre-1999 system was split into three parts, with pension funding in II and III pillar governed by principles definitely different than counter-poverty and counter-exclusion functions. Improving the deficit of the public pension (and implicit pension debt) and developing capital market with help of pension funds more accurately describe objectives of this reform.
- The explicit objective of 2013-turnabout was of accounting and financial nature as well. Reformers' endeavours have been aimed at cutting systemic costs in the sake of reduction in the budget deficits and public debt on the one hand and at revitalization of privately managed pension funding on the other hand.

Conclusions

Historical approach reveals a departure in Polish pension-system designing from functions of mostly social and political nature to goals related with private and/or public finance. Since 1999 the reforms seem to constitute two interlocking streams of change aimed at i) relief to public finance ii) expansion of pension funding and financial market development.

After several decades under new circumstances publicly managed system of mandatory pension saving was said to be implicitly insolvent. Political consciousness of this development induced reforms in the 1990s that were believed to constrain the financial consequences of state implicit guarantees and, thus, public pension debt. This was achieved by shifting from DB to DC which did not, however, improve situation in general government sector. Introducing pension funding and privatisation of the pension industry was of help in the sense of dispersing responsibility for diminishing rate of replacement. However, mandatory funding is controversial from perspective of the general government finance due to transfers of a percentage of contribution raised by public agency ZUS away to OFEs. In

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

spite of this structural flaw which actually compelled the state budget to provide donations to ZUS mandatory pension funding was introduced and maintained.

Although pension funds are neither solution to the implicit insolvency problem nor source of fiscal relief (Chełchowski, 2001) this institutional arrangement has found support at every stage of contemporary pension reforms in Poland. Taking this under consideration, introducing and expansion of pension funding can be seen as an end in itself which is tightly related to financial market development. As a matter of fact, the OFE project as well as pension funding on voluntary basis meant inviting foreign capital to emerging market economy of Poland. Last paragraphs of the previous section provide arguments that this finding remains valid however impressed we could be by recent radical change concerning OFEs.

The two goals, however, are in contradiction to each other, and this makes a paradox of pension reforming in Poland. On the one hand, there is a strain to improve public finance. On the other hand, expansion of pension funding by private agents requires allowing real tax money and contributions to outflow from general government sector to the privately managed tiers.

The analysis that has helped us to identify the two contradictory policy objectives makes the picture of recent reforming more clear. There is some logic in recent thinking on and reforming of the pension funding in II pillar and III pillar. The OFEs became a victim of reforming along fiscal lines in the sake of relief to public finance. The Rostowski's reforms were a blow against expansion of pension funding and financial markets due to down-scaling of the OFEs. However, the review of 2013- and 2014- design, unexpectedly enough, resulted in conclusion that at present reforming is focused on revitalization of pension funds. It was argued that both some 2013 regulations and the 2014 project as a whole constitute to some extent the compensation and act in favour of financial market development, with new opportunities of doing business given to OFEs and mass membership in funded voluntary pension plans projected.

The recent focus on pension funding may make distress in public finance recurrent. Are the contemporary pension reforms more about expansion of the financial sector than anything else then?

**The Role of the Level of Development,
Geographical Factors, and Culture for
the Efficacy of Economic Freedom**

JEL Classification: *H10; O10; P50; P51*

Keywords: *economic freedom; institutions; economic development; geopolitics; culture*

Abstract: There are many studies focused on the role of economic freedom in creating conditions supportive for economic growth. Most of the recommendations in this area are based on the observations of the highly developed countries. But is it reasonable to generalize these findings to the other countries, independently from their conditions? Contemporary the number of the research conducted for the countries outside the world's forefront rises. Results are varied – some elements of economic freedom seem to be effective unconditionally, some of them bring different results. The aim of the paper is to examine the role of such factors as a stage of economic development, geographical location, and culture in the context of the efficacy of economic freedom. The study was conducted with usage of regression models for panel data and based on the indicators connected with economic freedom and economic growth.

Introduction

A discussion on the optimal level of public regulation has a long history among the economists. Many researchers indicate economic freedom as important determinant of achieving a high level of welfare. But, not all research bring the same results – it is still questionable which elements of economic freedom are important and whether economic freedom is required in all spheres of economy and works for each country. Most of the research are usually based on the highly developed countries. Western world however has its specific, as a result of the history, culture, geographical conditions etc. The question that can be raised is if the results true for western developed countries are also true for the rest of the world. The aim of the paper isn't set that widely. The research is focused on the diversification of the results of analysing the impact of economic freedom on GDP pc when the level of domestic product, geographical location and culture are taken into account. The purpose of the research is to examine the role of such factors as a stage of economic development, geographical location, and culture in the context of the efficacy of economic freedom. The study was conducted with usage of regression models with fixed effect for 178 countries in period 1995-2015. The indicators used in the analysis are the Index of Economic Freedom elaborated by Heritage Foundation and GDP pc (data form International Monetary Fund). Countries were analysed in three cross sections: economic (the level of GDP pc), geographical location (continent), and cultural (on the basis of Huntington's classification known as "the clash of the civilization theory").

Literature review

Economic freedom is one of the aspects considered as a resource of the socio-economic welfare. Studies on the capability of provision of the most effective solutions by market mechanism have accompanied economics from the beginnings, but also advocates of the public intervention have important place in the history of economic thought. It is possible to speak about market mechanism, when there are settled rules of exchange, communication, transferring of property rights, establishing the means of payment. Otherwise making rational decisions wouldn't be possible. From the other side the state is considered as the one responsible for delivering an institutional order (Stankiewicz, 2005). Both regulators – market mecha-

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

nism and state – are burdened with imperfections, and optimal level of public regulation is still under consideration of the economists.

Provision of empirical evidences for theories needs concrete measures of the phenomenon – in case of economic freedom such attempts began in 80s. Earlier efforts in measuring freedom were concentrated on political and human rights rather than on economic liberty. Economic aspects in measuring of freedom appeared in studies published in 1982 and provided by L. M. Wright in collaboration with Freedom House in form of indicator of property rights (Wright, 1982, pp. 51-90; Leblang, 1996, pp. 5-26). The possibilities of measurement of economic freedom were also the subject of the public debate since 1984, when the meeting of Mont Pelerin Society (the society founded by F. A. von Hayek) took place in Cambridge (Konratowicz, 2013, p. 29). Contemporary the most popular and complex indicators for measuring economic freedom are: Economic Freedom of the World – EFW (by Fraser Institute), and Index of Economic Freedom – IEF (by Heritage Foundation). First one is based on 5 main components (Size of Government: Expenditures, Taxes, and Enterprises, Legal Structure and Security of Property Rights, Access to Sound Money, Freedom to Trade Internationally, Regulation of Credit, Labor, and Business), and is published since 1996, currently for almost 150 countries (Gwartney, Lawson, & Hall, 2014). The second one covers 4 main areas (Rule of Law, Limited Government, Regulatory Efficiency, Open Markets), and is available for over 180 countries since 1995 (Miller & Kim, 2015). Except of EFW and IEF there are also such measures as Doing Business (published by World Bank), Product Market Regulation Index (included in OECD statistics), some elements of economic freedom (mainly connected with property rights, and barriers for entrepreneurship) are also present in other measures of institutions, quality of governance, in so called coordination indices developed under theories of varieties of capitalism (Hall & Gingerich, 2009, pp. 449-482; Zielenkiewicz, 2014, pp. 21-37), in measures connected with competitiveness, innovations (e.g. Global Competitiveness Index, Global Innovation Index) or knowledge based economy (Balcerzak, 2009, pp. 713-742).

Simultaneously with works on developing the measures of economic freedom publications with empirical evidences appeared. J. C. Hall and R. A. Larson (2014, pp. 1-19) made wide meta-analysis of over 400 research based on EFW. As authors conclude, from 198 articles, where EFW was an independent variable, “over two-thirds of these studies found economic freedom to correspond to a “good” outcome such as faster growth, better

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

living standards, more happiness, etc. Less than 4% of the sample found economic freedom to be associated with a “bad” outcome such as increased income inequality”. In 28% of cases results were mixed (Hall & Larson, 2014, pp. 1-19).

In the research, where Granger causality test was used, results show that elements of economic freedom are usually causal for economic outcomes (e.g. Far, Lord, & Wolfenbarger, 1998, pp. 247-262; Vega-Gordillo & Alvarez-Arce, 2003, pp. 199-215, Piątek et al., 2013, pp. 267-288). However, results are often diverse for different areas of economic freedom in terms of significance and even direction of relationship (Sturm & De Haan, 2000, pp. 215-241; Carlsson & Lundström 2002, pp. 335-344; Dawson, 2003, pp. 479-495; Berggren, 2003, pp. 193-212).

An important issue connected with research on impact of economic freedom on economies' prosperity is that earlier studies are usually focused on western, developed countries, so results may be biased and not necessary true for the countries in other conditions. D. Rodrik, A. Subramanian, and F. Trebbi (2002, pp. 131-165) claim that the impact of institutions has primacy to geopolitical factors for economic growth. While the level of economic freedom is an element of institutional framework, the question about independency of effects of economic freedom from factors connected with geography and political conditions can arise. Historically, geographical issues played an important role: such factors like costal location, climate, natural resources had an impact on development of cities and countries. Contemporary transport system and agricultural technologies are developed, sources of comparative advantages have changed, but does it mean that geographical factors don't matter anymore? There still are the issues connected with costs, availability of technologies, and proximity of developed countries (Sachs, 1995).

Another important factor is the culture. A wide research on the determinants of government performance was published by team from Harvard University and The University of Chicago. Authors conclude: “These results present clear evidence of systematic influence of historical circumstances, as captured by ethnolinguistic heterogeneity, legal origins, and religion, on government performance. Governmental performance is surely in part determined by economic development, but it is also shaped by systematic variation in the histories of individual countries.” (La Porta et al, 1999, pp. 222-279)

As measures of economic freedom became available for more and more countries, it is possible to verify results with taking into account different

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

circumstances. Last years brought an increase of the research based on data from countries other than the “world’s forefront”. Some results suggest the great impact of the other factors than institutional framework. E. g. studies conducted for economies in transition show that initial conditions matter and are more important than regulation changes (Heybey & Murrell, 1999, pp. 121-137). Regression analysis conducted by M. Brycz (2013, pp. 211-232) for European Union shows some diversity of results between old and new member states as regards to property rights – in second group relation was negative, what can be a result of mistakes in privatization as well as of some benefits that less innovative countries can get from not respecting the intellectual property. Similar benefits can be observed also in case of so called Asian Tigers. From static point of view such countries might not have reasons for applying property rights. But in long term the problem of “average-income trap” may appear. The research conducted for developing and transition countries with usage of Bertelsmann Stiftung Transformation Index shows that property rights change statistical importance and direction of relationship with economic growth dependently on the level of development (Zielenkiewicz, 2015). Summing up, the results of previous studies justify analysing economic freedom with taking into account factors such as the level of development, culture or geographical aspects.

Methodology of the research

The research was conducted for 178 countries on the basis of the Index of Economic Freedom (IEF) developed by Heritage Foundation, and data published by International Monetary Fund and World Bank. The analysis covers years 1995-2015 (the period where data were available). The evaluation of economic performance (to measure the effects of economic freedom) was based on GDP per capita. The aim of the research was to verify whether the relationship between different areas of economic freedom and the level of income depends (in terms of its direction and importance) on factors connected with the level of GDP pc, geographical location, and culture. For this purpose firstly the countries were analysed together (in order to check general relationships), then were divided into groups on the basis of the following criteria:

- the level of GDP pc;
- continent where the country is located;
- culture (with usage of Huntington’s classification).

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

The analysis conducted for groups of countries was focused on the goodness of fit of the models (in order to test whether the variability of characteristics do explain variability of GDP's level, when factors listed above are taken into account), statistical importance of the variables, and the direction of the relationship. Data were analysed with usage of linear models of regression with fixed effect:

$$Y_{it} = \beta X_{it} + \alpha_i + \varepsilon_{it}, \quad i = 1, \dots, n,$$

where:

Y_{it} – explained variables (GDP per capita),

β – vector parameter,

X_{it} – matrix of explanatory variables (ten components of IEF),

α_i – time-invariant component,

ε_{it} – idiosyncratic error,

n – number of countries.

Fixed effect allows to remove the effect of assumed time-invariant characteristics from the predictor variables and to assess the predictors' net effect, when each entity (in this case – a country) has its own individual characteristics that may have impact on the predictor variables (Cameron, Trivedi, 2010, pp. 237-238). The choice between models with random and fixed effects was based on the Hausman test.

GDP used in the research is GDP based on purchasing-power-parity per capita in current international dollar published by IMF. It is important to mention that in case of poorer countries the quality of the data is always a questionable issue (often GDP isn't calculated precisely but only estimated by the government or statistical institutions), therefore a risk of some bias in the results exists.

Index of Economic Freedom used in the research was elaborated by Heritage Foundation and published for first time in 1995. The index covers ten components divided into four groups presented in the table 1. For each category countries are evaluated in range from 0 to 100, where 0 means lack of freedom, and 100 full freedom. The original version of IEF didn't include Labor Freedom – it appeared as a component of IEF in 2005.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

Table 24. Construction of Index of Economic Freedom

Index of Economic Freedom	Rule of Law	Property Rights (PR) Freedom from Corruption (FC)
	Limited Government	Fiscal Freedom (FisF) Government Spending (GS)
	Regulatory Efficiency	Business Freedom (BF) Monetary Freedom (MF) Labour Freedom (LF)
	Open Markets	Trade Freedom (TF) Investment Freedom (IF) Financial Freedom (FinF)

Source: Heritage Foundation (access form March 2015).

Additional explanation is needed in case of Government Spending. This component is based on the level of government expenditures (including consumption and transfers) as a percentage of GDP, and inverted, so the higher level of government expenditures results as the lower level of the index. However, zero does not mean that there is no private consumption in the economy, because expenditures (GE) are corrected with accordance to the formula: $GE_i = 100 - \alpha (\text{Expenditures}_i)^2$, where α is a coefficient to control for variation among scores (set by Heritage Foundation at 0,03). Therefore $GS = 0$ means that government expenditures exceeded the level of about 57 percentage of GDP (Heritage Foundation, 2015).

IEF was chosen due to its complexity (it contains 10 areas of economic freedom), relatively long period of calculations (index is available since 1995), and availability for many countries (nowadays it is published for 186 countries; not for all of them GDP was available, so number of countries in the research is 178).

Regression analysis of the relationship between components of IEF and GDP

Table 2 shows results of estimation for models (coefficients, standard errors, and statistical importance of the variables) without dividing countries into any groups.

Source: Own study.

First model includes all variables, the second one only these which are statistically important. In both cases coefficients of determination (R²) are similar and suggest that approximately 40% of variability of GDP pc can be explained by variability of the level of economic freedom. The factors that occurred as statistically unimportant are: Property Rights, Government Spending, and Financial Freedom. With the exception of Monetary and Labor Freedom, components of IEF are positively related with GDP pc. The highest coefficient among positively related variables can be noticed in case of Fiscal Freedom, and – at the second place – Trade Freedom. These two factors, as well as Business Freedom and Freedom from Corruption are usually positively correlated with economic growth, independently from the diversity of the countries.

Tables 3-5 contain results (direction of relationship, statistical importance of variables, measures of goodness of fit) of the analysis for countries divided into groups by income (table 3), continent (table 4), and culture (table 5). Models are again with fixed effects.

In order to test, whether the results are going to change, when the level of domestic income is taken into account, countries were divided into

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

groups dependently on the level of GDP pc. Most popular classifications of countries in terms of development come from World Bank, International Monetary Fund, and United Nations (Nielsen, pp. 7-18). World Bank recognizes four main groups: Low income (\$1,035 or less); Lower middle income (\$1,036 to \$4,085); Upper middle income (\$4,086 to \$12,615); High income (\$12,616 or more). UN's classification is based on Human Development Index and divides countries also into four groups: low-, medium-, high-, and very high-human development. IMF uses main division on Advanced economies (Euro area, Major advanced economies (G7), Other advanced economies (Advanced economies excluding G7 and euro area), European Union) and Emerging market and developing economies (Commonwealth of Independent States, Emerging and developing Asia, Emerging and developing Europe, Latin America and the Caribbean, Middle East, North Africa, Afghanistan, and Pakistan, Sub-Saharan Africa). Because the analysis is based on other unit than classifications mentioned above, and due to the comparison of results for different versions of division, countries were divided into six groups by GDP pc. In case of countries in the range from \$1000 to \$2000 there are two models presented – the first one with all variables which occurred as statistically important, and the second one without these variables where probability was under 0,1 and with higher R².

As can be seen in table 3, coefficients of determinations are relatively low, but also diverse. In case of countries with GDP pc below \$1000 the variability of GDP cannot be explained by variability of IEF's components. In this group such results were predictable: these often are countries in conflicts, located in hard climate, with large mortality rate, diseases, and hunger burden, without access to the basic sanitation and clean water. A bias due to the quality of data in case of the poorest countries also cannot be ruled. The highest level of R² (33,11%) can be observed in the \$4000-\$7000 group, which isn't a robust result. Thus, what can be seen, is that direction of the relationship of some variables and their statistical importance change across groups. Property Rights, and Government Spending in three groups appear as negatively related, Financial Freedom – in one case (\$2000-\$4000). In all groups a statistically important and positively related element of economic freedom is Trade Freedom. As relatively independent from the level of income can be also considered Freedom from Corruption and Fiscal Freedom (positive relation in five groups).

For the analysis of geographical location simple continental classification was used. It is more common to divide Africa onto at least two parts: northern and southern, but in groups based on culture such division was made, hence groups would be duplicated. North America was omitted because of too low number of countries to perform the analysis.

According to the results (table 4), only in case of Oceania R² was nearly 40%, in other cases models based on IEF do not explain the variability of GDP. That means that other factors must play role, and IEF is not a good descriptor of changes of income, when countries are analysed in respect of location.

The analysis based on culture (table 5) refers to Huntington's classification of civilizations (Huntington, 1993, pp. 22-49), related to cultural identity (mainly religion). Countries are not internally homogeneous in this respect, but were classified due to the majority present in the countries and historical background. African culture covers Southern, Middle, and Eastern Africa. Islamic culture include countries of Northern Africa, Middle East, Southwestern continental Asia, and Asian islands at the South. Latin civilization refers to Central and South America. Orthodox group includes mainly the former Soviet Union, the former Yugoslavia (without Croatia and Slovenia), and also Bulgaria, Romania, Greece, and Cyprus. Eastern

culture in Huntington's classification is differentiated: Japan is considered separately; Sinic civilization describes mainly China, but also Singapore, Taiwan, both Koreas, and Vietnam; Hindu group besides India also contains Nepal, and partly Bhutan; Buddhist countries are: partly Bhutan, Cambodia, Laos, Mongolia, Myanmar (Burma), Sri Lanka, Thailand (also Tibet which is not included in public statistics due to Chinese occupation). In the analysis these groups were taken as one. Western world includes mainly North America, Australia and Oceania, and most of Europe.

Coefficients of determination are highest in case of Islamic (36,5%) and Sinic/Hindu/Buddhist group (31,58%), what means that in these groups impact of economic freedom on income's variability is noticeable. In other cases again other factors than IEF must be more important. Trade Freedom seems to be the most independent from cultural circumstances factor – it is

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

positively related with GDP pc and statistically important in five groups. Similarly – Freedom of Corruption and Fiscal Freedom in four groups. Business Freedom and Investment Freedom are rather positively related, with an exception of one group in case of each of the indicators, where relation was negative, but with low statistical importance. Property Rights appear as negatively related in four group, and positively related in one case (Islamic culture). Mixed results can be observed in case of Government Spending (positive relationship in one group, negative in two groups), Labor Freedom (positive – one, negative – one), Monetary Freedom (positive – one, negative – two). Financial Freedom was statistically important only in one group.

Conclusions

The research conducted in the paper does not allow for rejecting the hypothesis that the analysis of the influence of economic freedom on countries' economic performance requires to consider also factors such as the geographical, cultural and related to the level of development circumstances. When countries are analysed in sections related to these factors, models based solely on components of the Index of Economic Freedom most often poorly explain the variability of the countries' economic outcome. Some of the elements of economic freedom seem to work regardless of the circumstances of the countries – that is freedom connected with trade, fiscal policy and control of corruption. But results for other areas of economic freedom are mixed. Such results are in line also with the observations of other researchers who indicate the importance of a number of components in the selecting of the model of public regulation. The study presented in the paper is preliminary. Institutional changes often bring effects many years after the implementation, which requires an analysis of the lag effect. This is going to be examined in the future research. Future research also are going to be expanded to include other aspects associated with affecting the effects of changing the level of economic freedom.

**Unemployment and Labor Market Policy
in Visegrad Group Countries***

JEL Classification: *A11*

Keywords: *unemployment; labor market policy; discrimination; Visegrad Group countries*

Abstract: In the recent years, an economic crisis has appeared in most economies. It affected the labor market situation. This article refers to changes in the labor markets of the Visegrad Group countries. The analysis concerns the relations between the economic crisis, the level and structure of unemployment (taking into account the situation of women and young people as the groups strongly exposed to unemployment), and the level and structure of expenditures within the labor market policy. The article is based on data published by Eurostat, using the tools of descriptive statistics, and statistical indexes, in particular. The research period covers the years 2007-2012, which is dictated by the availability of comparable statistical data. An analysis of the data indicates that the economic crisis increased the economic activity of the population, which contributed to an increase in unemployment. There is no discrimination against women in the labor market, but there has been a serious increase in unemployment among young people. With the increase in unemployment, the expenditures on the total labor market policy have increased, as have those on passive labor market policies and labor market service. Expenditures on active labor market policies (ALMPs) grow relatively more slowly, which may be especially evident in the case of expenditure on training.

* This article is the output of the research grant BK/216/ROZ1/2014.

Introduction

The level of unemployment and its structure mainly depend on the economic situation. A period of an economic crisis is characterized by a reduction of labor demand and a rising level of unemployment, whereas a period of economic recovery entails the opposite phenomenon. With higher levels of unemployment, one may access the additional resources for labor market policy activated by the state in order to avoid turning this situation into a phenomenon of long-term unemployment. In the context of labor market policy, the state has a range of instruments at its disposal, which, in various ways, support the unemployed in the job search process.

Instruments of the labor market policy should be tailored to the current situation and trends in the structure of unemployment. The labor markets of individual countries do not always respond to changes in the economic conditions in a way presented in theoretical studies. Labor market reactions are dependent on many factors, the most important of which seem to be the level of economic development and structure of the economy (the structure of employment by the sectors). To avoid these sources of differentiated labor market situations, the subject of the analysis in this article is the countries of the so-called Visegrad Group. These countries may be treated as operating at a similar level of economic development and are characterized by a similar structure of employment.

The evidence-based theoretical model hypothesis in this article states that the economic crisis has caused an increase in unemployment, a rise of discrimination in the labor market (e.g., on women and youth) and a change in the level and structure of expenditures in the labor market policy (LMP) adapted to the changes in the labor market.

To verify the hypothesis above, an analysis of the data related to the situation in the labor market, published by Eurostat for the Czech Republic, Hungary, Poland, and Slovakia in the years 2007-2012, has been carried out.

Methodology of the research

An objective of this work is to verify how the labor markets of the Visegrad Group countries respond to changes in the economic conditions in accordance with the literature model and, therefore, to what extent they may use the resulting recommendations to reduce unemployment. The selection of countries is dictated by their similarity in reference to the level of

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

economic development. It allows for a reduction of the factors other than the economic situation that have an impact on unemployment and the methods of its prevention. The research problem determines the methodology that has been applied. First, the analysis of the literature describing the model of the labor market response to the changes in economic conditions has been carried out, which enabled us to state the hypothesis of this article. This model has been updated with the results published in other publications, which are related to the particular problem (on the changes of activities and the presence of discrimination in the labor market).

The analysis of unemployment and prevention methods in the Visegrad Group countries was based on the data published by Eurostat. The year 2007 was chosen as the beginning of the analyzed period when positive economic trends were still visible. The end of the research period is the year 2012 because until this year, the data on the labor market policy were available. The article analyzes the changes in the level of economic growth and the accompanying changes in the level and structure of unemployment, as well as changes in the level and structure of expenditures on labor market policy. The method of statistical analysis has been applied in relation to the particular changes in the various quantities characterizing the labor market, mainly using the index method.

Unemployment and labor market policy in theory

Economic fluctuations, which usually appear first in the financial market, cause changes in the goods market and the labor market (in the form of changes in the level and structure of employment and unemployment). The economic crisis causes a decrease in the demand for work reported by employers (Neumeyer & Perri, 2005, pp. 545-580; Andolfatto, 1996, pp. 112-132; Zieliński & Jonek-Kowalska, 2011, p.46). This situation may be partly balanced by the response to the supply side of the labor market, which may go two way. On the one hand, the supply of work falls because of the appearance of the so-called “discouraged unemployed” (people who have lost their jobs and do not register in labor offices or the ones who resign from the status of the unemployed), who will return to the labor market when the employment prospects have substantially improved (Blundell et al., 2008, pp. 421–453; Pissarides, 2000, p. 172; Góra, 2005, p. 29). On the other hand, the supply of labor increases, thanks to the effect of the so-called “additional employee”, that is, the emergence of workers who thus far, have been professionally inactive in the labor market, as they have come

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

from families whose incomes have decreased due to the loss of employment by the “main breadwinner” (Cahuc & Le Barbanchon, 2010, pp. 196-205). In the literature, it is assumed that the effect of the “discouraged unemployed” is usually greater than the effect of the “additional employee” thus, the economic downturn entails the reduction of professional activity (and vice versa) (Pissarides, 2000, pp. 170-174; Kwiatkowski, 2002, p. 32; Coile & Levine, 2007, pp. 1902-1919).

An analysis of the statistical data on the labor markets in six largest EU countries during the recent economic crisis, contradicts the theoretical assumptions, unfortunately. In most of the countries the years 2008-2010 brought an increase in the professional activity of the population, and in half of them (France, the UK, and Spain), the increase in unemployment outmatched the decline in employment. Thus, the effect of “additional employees” was higher than the effect of “discouraged unemployed” persons (Zieliński et al., 2014, pp. 765-766).

The period of economic crisis is characterized by deterioration in the structure of unemployment in the form of increased participation of the so-called “problem groups” in total unemployment. The “problem groups” are classified as those with unfavorable socio-demographic characteristics, which result in a worse situation in the labor market. Among these problem groups, we may distinguish the following: women, young people, low-skilled persons, older workers, workers in declining industries, those working part-time, the disabled, etc. (Maksim, 2001, pp. 5-7). The increase of participation of these groups in total unemployment contributes to the growth of long-term unemployment and decreased professional activity (groups of discouraged unemployed) (Góra, 1994, p. 212). An economic downturn reduces the liquidity of the labor market because employers often protect their employees from dismissals, and one of the first measures to reduce the scale of the necessary reduction in employment is to suspend the inflow of a new workforce. Such a strategy adopted by employers particularly affects young people, including school graduates, who are also perceived by employers as being low-skilled, because they do not have any professional experience. Staying outside the group of employed leads to the depreciation of human capital concerning graduates and causes perturbations in their careers (Wincenciak, 2010, pp. 859-860). The situation of young people in the period of accelerating economic growth usually improves, when new businesses are created and the existing ones usually want to increase and supplement their staff.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

Empirical studies confirm the discrimination of problem groups on the labor market, which is reflected in higher unemployment and lower wage levels. This occurs in relation to women (Kraal et al., 2010; Shortland, 2009; Bardasi, Monfardini, 2006; Rutkowski, 2006), the youth (Verick, 2011; Rutkowski, 2006; Golsch, 2004), low-skilled workers and low levels of education (Belan et al., 2010; Tomé, 2007; Charlot & Malherbet, 2013), immigrants, and ethnic minorities (Sa, 2011; Pereira, 2012).

The basic instrument of the state intervention aimed at reducing the level of unemployment is the labor market policy. Through it, a given country tries to adjust the structure of labor supply to the demand and to counter the imbalance in the specific segments of the labor market. Among the objectives of the labor market policy, different purposes may be listed, such as the purpose of employment (increase in employment and decrease in unemployment), structural purpose (reducing a mismatch of supply and demand for labor), production purpose (increasing workforce productivity), and social purpose (ensuring social security and leading to professional integration of the unemployed) (Wiśniewski, 1999, p. 20; Jarmołowicz & Knapińska, 2005, p. 95).

The instruments of labor market policy are usually divided into the passive and active ones. The passive instruments are of a protective nature, and their goal is to reduce the risk of a sudden drop in incomes and the associated threats (e.g., extending the scope of poverty, social exclusion). The passive labor market policy instruments including benefits for the unemployed, early retirement, and severance pay for the dismissed. The active labor market policy instruments are designed to increase the chances of permanent employment of the unemployed (Jarmołowicz & Knapińska, 2005, p. 97). In addition to the prevention of deactivation of the unemployed, they are aimed at activating the inactive people. Among the activities in the field of an active labor market policy, the following are most often mentioned (Kluve et al., 2007, pp. 27-28):

- labor market services (job search assistance) – job agency and counseling conducted by the public employment services (labor offices), which decrease the exploration costs on the labor market (both for employers and employees),
- training programs – improving the qualifications of the unemployed through courses in training institutions, as well as apprenticeship and professional training at the headquarters of employers,
- supported employment and job creation – financial support for the employers of people who were previously unemployed, activation allow-

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

ances for the unemployed who are about to take jobs, subsidy and advisory assistance provided to the unemployed setting up their own businesses (start-up incentives),

- supported employment and rehabilitation – initiating special programs designed to promote employment of people with disabilities (supported employment, financing of trainings, additional job search assistance for the disabled),
- direct job creation – creation of temporary jobs in the public sector entities and non-governmental organizations, and
- special programs for young people – trainings, supported employment, job search assistance.

Job centers and career guidance counselors encourage the increase in the transparency of the labor market and the mobility of workers in reference to their qualifications and territory. The system of trainings and development of employees contribute to growth of their skills, mobility, and professional activity (Kukulak-Dolata, 2003, p. 185; Kryńska 2001, p. 57). The state, through employment services, may also decide to intervene in the labor market by subsidizing some of the costs connected with employment of the unemployed. Supported employment may take a form of organizing public works, intervention works, and preferential loans to employers who create new jobs or to the unemployed who are setting up their own businesses (Kukulak-Dolata, 2003, p. 185; Wiśniewski, 1999, pp. 27-30).

The effectiveness of activation of the unemployed depends on the economic situation. It decreases along with the increasing levels of unemployment, a decline in the labor market liquidity, and prolongation of the period of labor market imbalance (Wiśniewski, 1999, pp. 20-21; Kryńska 2001, p. 42). In addition, in the conditions of an economic crisis, the state operates at a strong reduction of the budget, and the transformation of supported employment into stable jobs is much less likely than in the conditions of prosperity.

The labor market policy is an essential tool for reducing the level of unemployment among the problem groups. Without the help from the state, these groups are exposed to long-term unemployment, resulting in professional consequences (reduction in qualifications), as well as psychological and health ones (Maksim, 2001, pp. 6-7; Góra, 1994, p. 212). Reducing long-term unemployment fosters the launch of special programs, which, in weak economic conditions, are often effective only temporarily. After they have finished a return of people taking part in these programs to the pool of the unemployed may be observed.

Unemployment and labor market policy in the Visegrad Group countries in the years 2007-2012

To illustrate the factors influencing the level and structure of unemployment, besides the changes in economic conditions, other factors have been taken into account; these factors include the population of people aged 15 to 65 years, the level of employment, and the professional activity rate, which are considered the quotient of the sum of the employed and unemployed and the total population aged 15 to 65 years (Table 1).

Table 1. The basic factors characterizing the situation of the labor market in the Visegrad Group countries in the years 2007-2012

Count-ry	Year	Real GDP growth rate	Population aged 15 to 65 years (1,000 persons)	Employment (1,000 persons)	Unemployment (1,000 persons)	Professional activity ratio
Czech Republic	2007	5.7	7346.7	4922.0	276	70.8
	2008	3.1	7410.4	5002.5	230	70.6

Source: Eurostat, economy and finance/annual national accounts/real GDP; population and social conditions/labor market/employment and unemployment (1.12.2014)

In the first year of the research, the analyzed countries were characterized by a very good economic situation, apart from Hungary, which reported economic stagnation in 2007. In the following year, there was a deterioration of economic growth, which, in 2009, took the form of a recession in

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

three of the analyzed countries. The recession did not occur in Poland, but the year 2009, in this case, was characterized by the lowest level of growth. It may be noticed that the two consecutive years brought an upturn, but in 2012, there was a “second downturn” of the economic situation in the Czech Republic and Hungary, where a recession appeared again.

When analyzing the changes in the level of employment and unemployment in response to changes in the economic conditions, it appears that their direction is consistent with the literature model. An economic slowdown was usually accompanied by a decline in employment and a rise in unemployment, but each of the analyzed countries shows some specificity. In the Czech Republic in 2011, there was a simultaneous decrease in employment and unemployment along with economic growth at the level of 1.8. The next year brought both employment and unemployment increases in the conditions of the recession. Hungary was characterized by an increase in employment in 2011-2012 when economic growth was at the level of 1.6 and recession at 1.7. The level of employment in Poland grew steadily (except for the year 2010), but there was a certain shift in the time of employment response to the economic situation (in 2010, the decline in employment at the economic growth of 3.9 occurred more as a reaction to the economic growth of 1.6 from the previous year). Since 2008, employment growth in Poland has been accompanied by an increase in the level of unemployment. The Slovak economy has been steadily losing jobs since 2008, and only a slight improvement was recorded in 2012, but it was actually a result of the economic recovery in the previous years (economic growth in 2012 was only 1.8). This phenomenon was accompanied by a gradual increase in unemployment, and in 2011, a decline was reported.

By analyzing changes in the population of people aged 15 to 65 years, its drop may be noticed in the first three of the analyzed countries, respectively, by 1.6% in the Czech Republic, 1.2% in Hungary, and 2.3% in Poland. Only Slovakia recorded an increase in the number of the working-age population by 0.2%. Despite this, the pressure on the labor market was growing as a result of an increase in the professional activity of the population, which was treated as a quotient of the sum of the employed and unemployed and the total population aged 15 to 65 years. Most strongly, in the years 2007-2012, the professional activity ratio rose in Poland (3.5%), and it may have been caused by a relatively low input level, and the best economic situation of the analyzed countries. In other analyzed countries, the professional activity ratio rose by 2.5% (Hungary), 1.9% (Czech Republic), and 1.4% (Slovakia). Similarly to the large EU countries men-

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

tioned in the introduction, in the period of 2008-2012 in the Visegrad Group countries, the effect of additional employees was higher than the effect of the discouraged unemployed. This may cause serious problems when it comes to the effectiveness of the labor market policy, as the previously unemployed people looking for work in a situation when the employers reduce the demand for labor, and, if necessary, they may complement their staff with the unemployed who have relatively high qualifications.

To investigate whether, in the labor markets of the Visegrad Group countries, one may notice deterioration in the situation of problem groups (women and youth) in response to the economic downturn, a compilation of change indexes in the number of the unemployed in the analyzed sections who were characterized by unemployment rates was prepared (Table 2).

When analyzing the unemployment rate, the rate for women differs little from the unemployment rates for the entire population. In the Czech Republic, the unemployment rate of women in the analyzed period was higher than the average by 1.0% to 1.4%, in Poland from 0.3% to 0.8%, and in Slovakia from 0% to 1.6%. In the case of Hungary since 2009, the unemployment rate of women was lower than or equal to the unemployment rate for the entire population. Between the years 2007 and 2012, the relative situation of women in the labor market, as measured by the proportion of unemployment rates in the Visegrad Group countries, improved, and the only exception was Poland where the difference in the disadvantages between the women's unemployment rate and the total unemployment rate grew by 0.1%.

Similar conclusions may be drawn based on the change indexes in the number of the unemployed. In the years of the worst economic situation (2009 and 2012), in only three cases out of eight, increasing indexes in the number of unemployed women were higher than the index for the entire population. For the whole period of 2007-2012, the index of increase in the number of unemployed women was significantly lower than the index for the population in the Czech Republic (by 9.5 points), Hungary (by 8.7 points), and Slovakia (by 12.2 points). This index grew more quickly only in Poland, but its growth was minimal (0.6 points). The above data allow us to conclude that the period of economic crisis (slowdown) did not contribute to the increase in discrimination against women in the labor market; in fact, in most of the countries, their situation in the labor market has relatively improved.

This situation is different in the case of young people. The observed unemployment rates of people aged up to 25 years in all countries strongly deviate upward from the average. In absolute terms, the worst situation of youth present in Slovakia (where the unemployment rate since 2010 has exceeded 30%), whereas the lowest unemployment rate of young people is reported in the Czech Republic (the unemployment rate throughout the whole period did not exceed 20%). Comparing the increase in the youth unemployment rate between the years 2007 and 2012, the highest increase occurred in Slovakia (13.4%), whereas the lowest occurred in Poland

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

(4.9%). Analyzing the changing relationship between the youth unemployment rate and the total unemployment rate in the years 2007-2012, it may be noticed that it deteriorated in all countries, respectively, in the Czech Republic, it increased from 2.0 to 2.8, in Hungary from 2.4 to 2.6, in Poland from 2.3 to 2.6, and in Slovakia from 1.8 to 2.4.

The deterioration of the situation of young people in the labor market is not as clear in the case of the analysis of change indexes in the number of the unemployed. On the one hand, in the worst economic years (2009 and 2012), in six cases out of eight, the index of increase in the number of the unemployed in the age group up to 25 years old was higher than the index for the entire population. On the other hand, for the entire 2007-2012 period, the increase in the index of the number of the unemployed in the group up to 25 years old was significantly higher than the index for the entire population only in the Czech Republic (by 25.7 points). In the other countries, the index of increase in the number of the unemployed in the group up to 25 years old was lower than the index for the population. The above data allow us to conclude that the period of economic crisis (slowdown) contributed to an increase in discrimination against people under the age of 25 years old in the labor market (as indicated by changes in the unemployment rate). Furthermore, the absolute level of unemployment in this group is growing relatively more slowly than in the total population in three of the analyzed countries, probably due to a delay of introduction into the labor market and / or a reduction in the size of this group because of demographic reasons (as indicated by the increase index in the number of the unemployed).

The most recent data on the expenditure on the labor market policy (LMP) are available for the year 2012 (in the case of Poland for 2011). To facilitate the analysis, the expenditures on LMP may be divided into three groups: labor market service (column 4 of Table 3), passive labor market policies (in Table 3, column 9), and active labor market policies (in Table 3, columns 5 to 8).

*1- labor market service; 2- training; 3- employment incentives; 4- supported employment and rehabilitation; 5- direct job creation and start-up incentives; 6- out-of-work income maintenance and support and early retirement

Source: Eurostat, population and social conditions/labor market/employment and unemployment/labor market policy/public expenditure on labor market policy (1.12.2014).

When analyzing the total LMP, it may be noticed that their highest levels of expenditure on LMP occurred in all analyzed countries in the year 2010, two years after the first downturn of the economic situation. It was also the year with the highest level of unemployment in the Czech Republic and Slovakia, as well as almost the highest in Hungary (about 1,000 more people were unemployed in 2012). Having high expenditures on LMP in 2010 was probably one of the reasons for reduction in the level of unemployment in the following year (in three of the analyzed countries) and the slowdown in unemployment growth in Poland.

The structure of expenditures on the LMP varied in the particular countries in different ways. In the Czech Republic, the amount of spending on passive labor market policies ranged from 44.1% in 2007 to 59.8% in 2009,

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

and then in subsequent years, it gradually fell. Therefore, the relation of this group of expenditures with the unemployment rate can be noticed. Expenditures on the labor market service were relatively stable, and the fluctuations of their share were mainly due to changes in the level of total LMP. As part of active labor market policies (ALMPs), an increase in total expenditures in 2010 can be observed, as well as a further increase in spending in 2011 in the group of supported employment and rehabilitation. The Czech Republic stands out among the examined countries in respect to an increase in spending on training during the growth of unemployment. This is probably because the unemployment rate in the Czech Republic is clearly the lowest among the examined countries (the highest level reached 7.3%). Further, at a low level of unemployment, the effectiveness of training as a way of reducing unemployment may prove to be successful.

Hungary shows very serious fluctuations in expenditures in passive labor market policies, which reached 59% in 2009 and 64.4% in 2011 and fell to 36.5% in 2012. Very serious fluctuations also occur in the context of labor market service, the shares of which fell sharply in 2011 (to 1.6%) to grow even more rapidly in the following year (to 10.5%). As a part of ALMPs, Hungary has not listed a group of expenditures for supported employment and rehabilitation. Throughout the whole period, the expenditures on training decreased to achieve a share of 0.3% in 2012. The Hungarian labor market policy focused on the expenditures in the group of direct job creation and start-up incentives, whose participation was by far the highest among the analyzed economies, and in 2012 even surpassed spending on passive labor market policies. The expenditures on employment incentives were relatively stable, and fluctuations in their share were mainly due to changes in the level of total LMP.

In Poland, the amount of expenditures on passive labor market policies in total LMP was the lowest among the examined countries during the first downturn, which is strongly linked to the fact that Poland managed to avoid the period of recession and associated mass dismissals of workers who were entitled to unemployment benefits. Just as in the Czech Republic, expenditures on labor market service were relatively stable, and their fluctuations were mainly due to changes in the level of total LMP. Since 2009, the share of expenditures on training gradually declined. Other groups of expenditures on ALMPs grew in the years 2009-2010. The growth in supported employment and rehabilitation was recorded in 2011, whereas shares of the other expenditure within ALMPs in 2011 significantly decreased.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

Slovakia was hit by the highest level of unemployment among the countries analyzed, even though it has spent by far the largest amount of resources on passive labor market policies, the share of which in 2009 reached 72.4%. In absolute terms, as well as relative ones, after the downturn in 2008, the expenditures on labor market service in Slovakia dropped. In terms of expenditures on ALMPs, the least was spent on trainings, approaching zero in 2011-2012 (the reasons for this may be low effectiveness of this instrument at the time of a high rate of unemployment). Among the most important ALMPs in Slovakia since 2010 are those for employment incentives. Significant resources are also spent on direct job creation and start-up incentives.

Conclusions

The statistical data analysis conducted in this paper allows us to draw the following conclusions:

1. In the Visegrad Group countries, there was a trend to increase the professional activity of the population, which were treated as the sum of the number of the employed and unemployed during the time of the last economic crisis. This results in a deepening of the labor market imbalance, and it reduces the effectiveness of the labor market policy (due to the fact that it activates people who, so far, have stayed away from the labor market, most of whom are low-skilled).
2. In the labor markets of Visegrad Group countries, the economic crisis did not lead to an increase in discrimination against women (in Hungary, since 2009, the unemployment rate of women was even lower than that of men), while the situation of young people deteriorated significantly. For young people the unemployment rate in all countries was more than twice as high as for the total population.
3. Expenditures on LMP are positively associated with the level of unemployment, and in most countries, there is also a positive relation of unemployment and spending on passive labor market policies.
4. The relation between spending on training and the level of unemployment was identified. These expenses are rising in the period of economic downturn with a relatively low unemployment rate, and they are falling with high rate of unemployment.
5. Priorities within ALMPs are varied. The Czech Republic and Poland, in recent years, have spent the most resources on supported employment and rehabilitation, while Hungary has spent the most resources on direct

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

job creation and start-up incentives, and Slovakia has spent the most on employment incentives.

6. The least stable labor market policy, from the perspective of changes in the share of expenditures within LMP, is supported by Hungary, whereas the most stable one is that of the Czech Republic.

These conclusions allow us to partially confirm the hypothesis stated in the introduction. The economic crisis increased the level of unemployment, and it also led to an increase in discrimination in the youth labor market and the rise in the level of LMP expenditures, which was caused by changes in the labor market. However, the part of the hypothesis about discrimination against women on the labor market was not confirmed. The variability of the changes in the structure of expenditures on ALMPs in the individual countries cannot provide any reliable reason to believe that they are responsive to the changes in the labor market.

The results of the analysis of the statistical data presented in this article may be treated as a prelude to further extended research. First of all, it would be advisable to study, for a longer period of time, to what extent the observed relations are statistically significant, especially to what extent the structure of LMP expenditures translates into the reduction of the level of unemployment. This would allow us to propose some adjustments of the labor market policies in an attempt to increase its effectiveness.

**Accession to the Eurozone as Lithuania's
Exit Strategy From the Currency Board
System**

JEL Classification: *E31; F31; F36*

Keywords: *Currency Board; Inflation; Euro Adoption; Lithuania*

Abstract: In the years 2004-2014 the Lithuania's exchange rate policy was based on a rigid currency board system. After a period of uncontested success in the fight against inflation in the first decade of the transition and economic growth, entering the ERM II in 2004 and efforts to adopt the euro were treated as an optimal exit strategy from the currency board system. However, the consequences of this exchange rate system in the following years (until 2014) prevented Lithuania from meeting the economic convergence criteria.

The starting point for the research is based on the theoretical analysis of literature studying benefits and risks associated with the use of the currency board system by the monetary authorities. The empirical analysis refers to the case of Lithuania and covers the years 2004-2014. The purpose of this analysis is to look at the effects of the use of the currency board system from the perspective of the convergence criteria of monetary nature and the extent of their implementation in the absence of opportunities for autonomous monetary policy.

Introduction

One of the modern varieties of the rigid exchange rate systems is the currency board system. It was used during the systemic transformation in the Baltic States - Lithuania and Estonia. While the use of the currency board system largely contributed to the stabilisation of the economy and the effective suppression of inflation in the first decade, after the accession to the European Union in 2004 it also began to show the negative consequences of this exchange rate system. In the Baltic States - in contrast to other economies in Central and Eastern Europe - after reaching the macroeconomic stabilisation no changes in the exchange rate system into a more flexible system were introduced. Both in Estonia and Lithuania rapid adoption of the euro was treated as an exit strategy from the currency board system (see Gulde et al., 2000; Brixiova et al., 2010, p. 222). However, despite the accession of these economies as early as June 2004 to the ERM II, in the subsequent years there were serious problems with meeting the convergence criteria, especially the inflation criterion. In addition, under the impossibility of carrying out an autonomous monetary policy as a result of the global financial crisis, these countries experienced a very deep economic downturn. Finally, Estonia was incorporated into the Eurozone on 1 January 2011, while Lithuania only on 1 January 2015. A particularly interesting case is the Lithuanian economy, which in 2006 ran less than 0.1 percentage point to meet the inflation criterion, and because of the limitations associated with the currency board system this criterion was possible only in 2014.

The purpose of this article is to confront the theoretical risks of a currency board with the experience of Lithuania. The conclusions from the analysis are universal as they permit to describe the consequences of the situation when it is not possible to run an autonomous monetary policy, both in good economic times and in the face of the global financial crisis.

Methodology of the research

The starting point for the research is - based on the studies of the specialist literature - the theoretical analysis of the benefits and risks associated with the use of a currency board system in the economy, particularly the consequences of renunciation by the monetary authorities of conducting autonomous monetary policy.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

The empirical analysis refers to the case of Lithuania and covers the years 2004-2014, i.e. the period within the ERM II. The purpose of this analysis is to look at the effects of the use of the currency board system in good economic times and in the crisis conditions through the prism of the extent to which the convergence criteria of the monetary nature were realised. What will also be taken into account is the experience of other economies that used the currency board system in modern times and moved away from the pursuit of such an exchange rate policy. This will enable answering the question whether the risks associated with the use of a currency board system are due to the specific conditions of a given economy or whether they stem from the essence of a rigid exchange rate system.

Benefits and risks of a currency board - theoretical analysis

Currency board (CB) is defined as a monetary institution that provides the exchange of the monetary base only in exchange for foreign currency representing foreign exchange reserves (Enoch & Gulde, 1998; Williamson, 1995, p. 2). The theoretical basis of the currency board system dates back to the year 1800; it was first introduced in 1849 in the British colony of Mauritius, and then widely used, mainly in the British colonies. It was most common in the 1940s and 1950s but then there was a shift from this exchange rate solution in favour of the independent national currency. Renewed interest in this system appeared in the early 1990s, when the currency board was introduced by the governments of Argentina, Estonia and Lithuania (see more Williamson, 1995, pp. 5-11; Wolf et al, 2008, pp. 7-18).

Theoretically, the institution of the currency board can replace the central bank or it may function besides the existing central bank. Foreign exchange reserves held by the CB correspond to 100-110% of the monetary base and are maintained in the currency which the national currency is linked to in the form of deposits of high liquidity and safety in reputable institutions. Only the currency of a country of high stability and low inflation, which is also the most important trading partner (see Gulde et al., 2000, pp. 5-6), can be selected as a currency anchor. In the currency board system there is a full convertibility of the national currency into the reserve currency, which means that at each request the central bank allows an exchange of the national banknotes and coins into foreign currency at a fixed rate. It does not exercise control over commercial banks and it does not function as the lender of last resort. The central bank cannot finance the

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

budget deficit and the monetary authorities are independent of political decisions. A commitment to the long-term use of the CB by appropriate legislation helps to enhance the credibility of the system (compare Hanke, 2002, pp. 204-206). Stronger commitment to maintain the currency board would entail greater benefits from the introduction of this exchange rate solution.

The main advantages of the introduction of the currency board include (see Imam, 2010, p. 20; Gulde et al., 2000, pp. 2-6; Wolf et al., 2008, pp. 27-30):

- increased macroeconomic policy discipline and its credibility (i.e. the disciplining effect);
- eliminated exchange rate risk in trade;
- lost ability of the central bank to conduct monetary policy aimed at achieving short-term goals, which is a message to the outside world of the strict observance of the rules;
- imported credible monetary policy from the outside (i.e. credibility effect);
- ‘anchored’ inflation at the level of the inflation occurring in the country which the currency exchange rate is tied with.

However, alongside the benefits of using a currency board system, related to the possibility of limiting inflation, the use of the exchange rate regime also involves certain risks for inflation trends from the outside. This is because the supply of money in the monetary system is dependent on the money issued by the reserve country (see Antas, 2001; Jakubiak, 2000). The reason for the creation of inflation in the currency board system can also be an increase in the money supply as a result of the influx of foreign capital and development of a positive balance of payments. Sławinski (2007, p. 289) sees renunciation by the monetary authorities of the ability to influence the level of real interest rates as the main source of threats to the currency board system. This is because it means the inability to conduct monetary policy, which cannot counteract the pro-cyclical changes in real interest rates, and could lead to a rapid accumulation of imbalances in the economy. In the event of any adverse external shocks the high rigidity of prices and wages may be associated with a decline in the competitiveness of the economy and hinder economic growth. In the currency board system automatic control of the money supply by matching at the level of the interest rate simultaneously causes significant fluctuations in interest rates. It is particularly fierce in a situation of declining confidence of foreign investors and capital flight. A developed and strong banking sector, which is well

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

able to cope with significant fluctuations in interest rates (Enoch & Gulde, 1998) is mentioned as a condition for the effective application of the currency board, and thus achieving the goal of curbing inflation.

**Currency board system in Lithuania before entering
the ERM II - historical overview**

In Lithuania the currency board (CB) system was introduced on 1 April 1994, after almost two years of the floating exchange rate regime. The Lithuanian litas (LTL) was pegged to the US dollar in the relation of 4 LTL = 1 USD (Alonso-Gamo et al., 2002, p. 5). The dollar served as the reserve currency since January 1994. Initially, Lithuania based its currency board model on the Estonian system. Two departments were part of the central bank: Foreign Department and Monetary Policy Department. The primary objective of the Bank of Lithuania, determined in the legislature, was to achieve monetary stability. The central bank was responsible for the monetary policy of the country, managed the foreign currency reserves, as well as monitored the use of the currency board system. In addition, it was responsible for the banking supervision. It could make loans to commercial banks and other financial institutions at risk of losing liquidity (the credit value, however, could not exceed 60% of the commitments of the assisted institution) (Bank of Lithuania, 1994). The change in the nominal exchange rate in Lithuania by the central bank could take place after the consultation with the government, and only in the case of extraordinary circumstances threatening the stability of the economy (Jakubiak, 2000, p. 10). This meant less restrictive protection of the currency board system in comparison with the countries in which the change is subject to the consent of the Parliament. The level of foreign currency reserves provided 100% coverage of the monetary base and liquid liabilities of the central bank. The scope of the obligations of the central bank, however, did not include loans, mainly from the International Monetary Fund.

The prerequisite for the decision to introduce the CB system in Lithuania was to quickly build full confidence of its own citizens and foreign investors in the domestic currency. The litas, pegged against the US dollar, also acted as an anti-inflationary anchor. The use of the CB system was designed to communicate the financial markets the lack of experience in the conduct of monetary policy will be compensated for by the observance of strict rules to ensure price stability. In 1997, after the crisis of the banking system in Lithuania, there was an attempt to change the currency board

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

system into a more flexible exchange rate system before joining the ERM II. In 1998, the Bank of Lithuania became a lender of last resort, but finally in 2000 the Bank officially resigned from conducting open market operations. The remaining strategic objective of the bank was to take care of price stability. In October of 1999, in connection with the growing ties between the Lithuanian economy and the European Union as well as the future Lithuania's accession to the Eurozone, the decision was taken to change the reserve currency from the dollar to the euro starting from February 2002 (see more Alonso-Gamo et al., 2002, pp. 4-11). The effect of this action was the phenomenon of 'dedollaring' of the economy in 2001-2002. After applying these changes, the dollar weakened significantly in relation to the national currency, although it was officially announced that the litas would not be devalued or revalued against the new currency anchor. Finally, the course was set at 1 euro = 3.4528 litas.

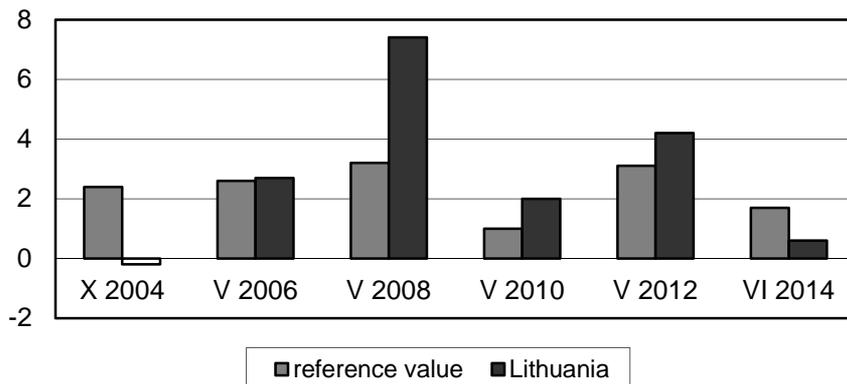

Along with the use of the CB system Lithuania enjoyed a lot of success in reducing inflation. Average annual inflation rate gradually declined: from 39.66% in 1994 to 24.62% in 1995 to 8.88% in 1996 and 5.07% in 1997. Even during the turmoil in global financial markets in the late 1990s (effects of the Czech, Asian and Russian crises), despite small fluctuations in individual months, the inflation rate persisted at a very low level - the average inflation rate was 0.75% in 1998 and 0.99% in 1999. In 2000-2003, the average annual inflation rate did not exceed 1.36%, and the country even experienced a temporary deflation (-1.13% in 2002). The fixed exchange rate and rapid liberalisation of capital flows contributed to the development of foreign trade and economic growth. Since 2000, Lithuania entered the path of rapid economic growth, recording the annual changes in the GDP volume from 4.23% in 2000 to as much as 10.25% in 2003. At the same time the exchange rate policy forced the authorities to conduct prudent fiscal policy (Sławiński, 2007, p. 280). In the first decade of using the currency board system, thus, many benefits revealed, especially in terms of suppressing inflation. In 1999-2004, the average annual inflation rate was the lowest among the economies of Central and Eastern Europe. However, the string of economic success of Lithuania - referred to as one of the "Baltic Tigers" - after joining the European Union in 2004, and later to the ERM II, symptoms began to appear indicating the existence of significant limitations associated with the use of such a restrictive exchange rate.

Monetary convergence in Lithuania in the conditions of the currency board

In connection with the strategy adopted by the monetary authorities of Lithuania - from the currency board to the euro (see Gulde et al., 2000, pp. 16-18), on 28 June 2004 the litas was included in the ERM II. Lithuania maintained its commitment to the use of the currency board and unchanged litas pegged to the euro. So restrictive exchange rate policy thus guaranteed meeting the first of the monetary criteria - exchange rate stability after two years in the ERM II, which was in June 2006. At the same time, however, it had a significant impact on the implementation of the other two monetary criteria – of price stability and of convergence of interest rates. It should be noted that the experience of other economies of Central and Eastern Europe showed a clear imperfection of the convergence criteria for the countries aspiring to join the euro zone, especially the inconsistency of the exchange rate and inflation criteria (see more Źuchowska, 2011, pp. 8-25).

The price stability criterion means that the rate of inflation, observed over a period of one year before the examination, does not exceed the inflation of the three EU member states with the most stable prices by more than 1.5 percentage points. Figure 1 shows the degree of meeting this criterion by Lithuania in the periods preceding the publication of the consecutive convergence reports. It is clear that this criterion was met in October 2004, that is, in the initial period in the ERM II, and then only in June 2014. In other reference periods the differences ranged from 1% to as much as 4.2%.

Figure 2. HICP in Lithuania against the Euro area average between January 2004 and November 2014 (monthly data y/y)

Source: Eurostat (27.12.2014).

The analysis of the historical data shows that the inflation in consumer prices in Lithuania remained at a relatively low level until mid-2006 (see Fig. 2). However, the problems of the rising inflation started already in May 2004 and were associated with the accession shock. In 2006 Lithuania minimally did not meet the criterion of the price stability and did not enter the euro area (12-month average rate of HICP inflation was 2.7%, which was just above the reference value stipulated in the Treaty, which was 2.6%). What should be noted while assessing the level of inflation in Lithuania during this period are the restrictions on the formation of the money supply by the central bank resulting from the application of the CB. The interest rates in the country were in fact related to the interest rates of the euro area, and the rigid link of the litas to the euro entailed a limited ability to respond to the short-term fluctuations in the inflation rate (Baran 2007, p. 42). Threats of rising inflation in Lithuania, which were then pointed out, include: harmonisation of excise duty to the EU level, dynamic output growth fueled by strong credit growth and low interest rates, as well as emerging bottlenecks in the labour market, which carry a risk of increasing unit labour costs and - consequently - domestic prices (ECB 2006, p. 20). The HICP inflation continued to rise sharply in 2007, reaching a record level of 11.6% in June 2008. At the same time the Lithuanian economy

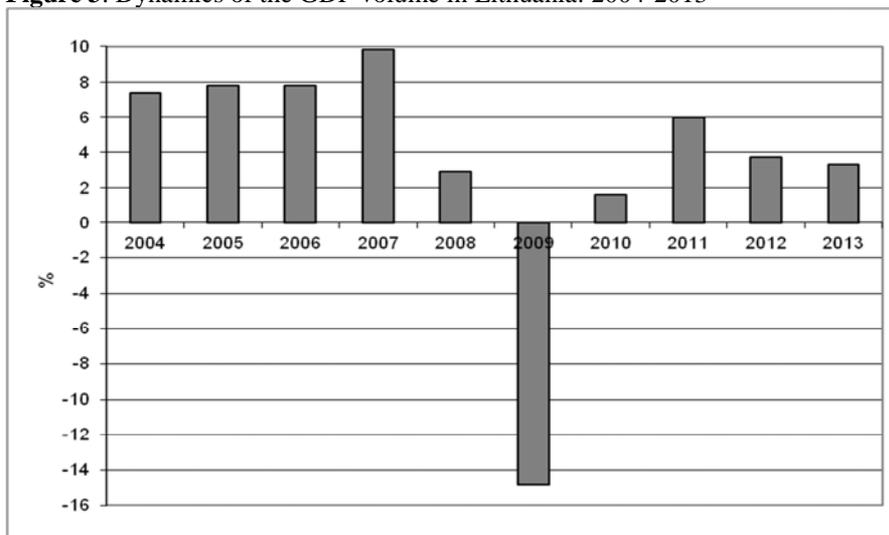

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

showed growing signs of overheating and emerging significant imbalances. In 2004-2006 the real GDP growth remained at a level above 7% and reached 9.8% in 2007 (see Fig. 3). It was mainly stimulated by the high domestic demand. While the economy rapidly hastened, after joining the EU there was an outflow of human resources, so unemployment fell to the historically low levels; as a result, unit labour costs increased significantly. The domestic demand boom ended abruptly in 2008, which was due to the weakening external demand as a result of the outbreak of the global financial crisis. Just as in other CEE countries, due to the crisis of confidence there was a rapid outflow of foreign capital from Lithuania. In view of the fact that the currency board system does not allow to run an autonomous monetary policy, the monetary authorities could not actively resist the deteriorating economic situation of the country (see more Purfield, 2010). For most of 2008 Lithuania - as the only Baltic economy - stood firm against a strong economic slowdown, but in the fourth quarter the GDP decreased by 2.2% y/y. In 2009, the GDP declined at a record high level of 14.8% y/y (see Fig. 3). The economic downturn during the global crisis caused a rapid disinflation process in the Lithuanian economy, which turned up into a periodic deflation. In the second half of 2008 there was a downward trend in inflation (see Fig. 2). In 2009, the HICP inflation fell sharply, with the June level of only 0.6% (y/y), while the period from July 2009 to August 2010 was characterised by a negative growth rate of consumer prices (deflation ranged from -0.3% to -4.3% (y/y)). This allowed Lithuania to regain price competitiveness of its economy. As noted in the Convergence Report of May 2010, such a situation in the field of inflation should be analysed against the background of a strong reduction in domestic spending and reduction of the price dynamics shaped on the global markets (ECB 2010, p. 46). The return of the GDP growth was associated with an increase in the inflation process in September 2010. The monthly inflation (y/y) increased steadily, in May 2011 reaching the level of 5% and then keeping up at a level above 4% until November 2011 (see Fig. 2). This was also associated with the increases in the global food and energy prices (ECB 2012, p. 83). In 2012, the inflation rate fluctuated around 2.4-3.6%. As a result of the favourable changes in the global commodity prices as well as a decline in food and administered prices, the downward trend in inflation continued in 2013: it fell from 2.6% in January to just 0.5% in December. By 2014, the ratio of consumer prices fluctuated around zero (see Fig. 2). The dynamics of inflation remained at a very low level; temporary deflation was also reported. In contrast, during the reference period - from May 2013 till April

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

2014 - the 12-month average rate of the HICP inflation in Lithuania was 0.6%, which was significantly lower than the 1.7% reference value for the criterion on price stability (ECB 2014, pp. 83-84). After 10 years in the exchange rate mechanism of ERM II Lithuania met the inflation criterion.

Figure 3. Dynamics of the GDP volume in Lithuania: 2004-2013

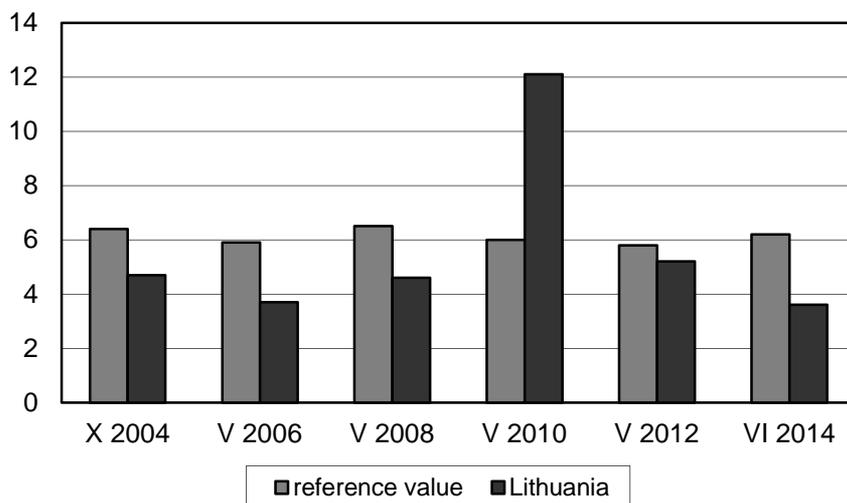

Source: Eurostat (25.12.2014).

The criterion for the convergence of interest rates means that within one year before the examination the Member State had an average nominal long-term interest rate that does not exceed by more than 2 percentage points that of the three EU member states with the most stable prices. As shown in Figure 4, Lithuania met this criterion, with the exception of the reference period after the global financial crisis from April 2009 to March 2010, when the long-term interest rate was above the reference value by 6.1%. This was due to the turmoil in the global financial markets, a downgrade of the country and a decrease in liquidity resources (ECB 2010, p. 47). Also in the field of meeting this monetary criterion there revealed negative consequences of the currency board. When economic growth fell below the potential rate, the monetary authorities of Lithuania could not lower the short-term interest rates to counteract their pro-cyclical changes and reduce the risk of recession. What is more, the more the pace of economic growth got reduced, the more the risk of default of domestic enterprises grew. There was an increase in the long-term interest rates and the likeli-

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

hood of a recession was growing. These consequences were especially pronounced during the global financial crisis (see Fig. 5). While between January 2004 and August 2008 the differences in the long-term interest rates did not exceed 1 percentage point, in the following months they increased to more than 5 percentage points in December 2008, and then exceeded 10 percentage points until November 2009 (long-term nominal interest rates in Lithuania were then as high as 14.5%). At the end of 2010, the nominal interest rate stood at 5.15%, which was slightly lower than before the onset of the turmoil in the global financial markets. In contrast, the differences between the Lithuanian long-term interest rate and the average for the euro area ranged only from 0.41 to 1.31 percentage points from January 2011 to the end of 2014 (see Fig. 5).

Figure 5. Nominal long-term interest rates in Lithuania against the euro area average

Source: Eurostat (25.12.2014)

After the period of success in the fight against inflation through a currency board system, serious problems arose in the Lithuanian economy from the excessive use of this exchange rate solution. The case of Lithuania showed that the country took the risk unnecessarily, just after the defeat of inflation. Such a restrictive policy led to a significant deterioration in the trade balance and current account balance in this country. The severity of the inflation process in the first years of the participation in the ERM II prevented the Lithuanian economy from a quick meeting of the inflation criterion and by the adoption of the euro - benefitting from a safe exit strategy. At the same time it deprived Lithuania of tools for a flexible response to the economic situation, which was particularly acute during the global financial crisis. The slowdown in inflation was recorded only during a deep economic recession. The inflation criterion and all the other convergence criteria were met only in the conditions of favourable changes in the world commodity prices and a decline in the food and administered prices between May 2013 and April 2014 (see Table in Appendix). On 1 January 2015 Lithuania was the last of the Baltic economies incorporated into the euro zone. However, in a monetary union, similarly to the terms of the currency board system, the monetary authorities will not be able to pursue independent monetary policy and thus the permanent maintenance of low

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

inflation in Lithuania can be difficult due to the continuation of the process of economic convergence (convergence of incomes and prices).

Lessons from the experience of Argentina and Estonia

The focus of this section is the experience of the economies which applied the currency board system since the early 1990, and then moved away from this restrictive foreign exchange solutions, i.e. Argentina (currency board in 1991-2001) and Estonia (currency board in 1992-2010).

The use of the currency board in Argentina and establishment of a fixed exchange rate against the US dollar, after unsuccessful attempts of introducing consecutive stabilisation programs in the 1980s and the loss of credibility of the monetary policy, brought success in the form of a permanent elimination of high inflation, which had been oppressing the country for decades. Additionally, the banking and public sectors were reformed. In a short time, Argentina transformed from a country with a high degree of regulation and protectionism into a liberal market economy (Sotomska-Krzystofik, 2003, p.48-49). However, the cost of this solution proved to be very high - the economy became vulnerable to external shocks. In the 1990s the economic growth was twice halted as a result of external factors. In 1995, the currency crisis in Mexico led Argentina to a currency crisis (due to the outflow of foreign capital), and the recession – the GDP fell by 2.8%. The country managed to survive the crisis with the help of the International Monetary Fund and in 1997 an economic growth of 8.1% was recorded. However, the effects of the strong devaluation of the Brazilian real in 1999 (a decrease by 40% in relation to the US dollar) were much more severe for the Argentine economy and led to a long-term economic recession. The fall in the GDP began in 1999; it was 3.3% and lasted until 2002, when the Argentine economy contracted by 10.9% (IMF, WEO 2014). In the context of the currency board system the monetary authorities did not have the opportunity to carry out the devaluation of the peso or lowering interest rates in order to stimulate economic growth. There was a loss of price competitiveness of the economy, the deterioration of the balance of trade and growth of external imbalance. In 1999-2001 Argentina also recorded deflation. After the initial successes, the currency board system itself became a cause of the erosion of the creditworthiness of Argentina. The investors showed rising concerns about how the monetary authorities - unable to conduct an autonomous monetary policy - would cope with the rising external debt (Sławiński, 2001, pp. 57-67). At the beginning of

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

December 2001, there was an escalation of the crisis – the deposits were completely frozen, foreign exchange reserves fell to 14.5 billion UDS (from 32.2 billion in 1999), and the government suspended the foreign debt service. As an exit strategy from the currency board system Argentina adopted a gradual transition to a floating exchange rate system. Initially a dual exchange rate system was introduced - in the settlements of foreign trade and capital flows the official parity was adopted by performing 29% devaluation, and in the remaining transactions the market rate was in force. The government was forced to intervene in order to prevent the deep depreciation of the peso against the US dollar. It was not able, however, to prevent it, even after the official introduction of the floating exchange rate system (Torre et al., 2003, pp. 20-21). As a result, the Argentine economy suffered the high cost of the application of the currency board.

Estonia's experience with the currency board system was very similar to that of Lithuania. In assessing the effectiveness of the currency board in Estonia in the 1990s we are definitely entitled to the conclusion that during this period the system performed its function well and - by a significant reduction of the inflation rate - contributed to control hyperinflation and achieve financial stability in the economy. In annual terms, in 1999 the inflation rate reached the lowest level (3.29%) since the introduction of the currency board system. Serious problems with inflation emerged in May 2004, after joining the European Union, and then the ERM II (see more Brixiova et al., 2010, pp. 204-205). In the coming years this prevented Estonia from meeting the inflation criterion in a time when all the other convergence criteria were met. One reason for the creation of inflation in the currency board system is an increase in the money supply as a result of the inflow of foreign capital. It was also influenced by increased lending in foreign currencies observed in Estonia after the accession to the European Union. This was due to the lack of exchange rate risk in the conditions of the currency board and constant persistence of lower interest rates in the euro area. In 2004 credits for the private sector accounted for 63.1% of GDP, and in 2006 for 86% of the GDP. This resulted in an increase in the foreign debt of Estonian banks. With a disturbingly low level of reserve assets (at the end of 2006, the state of the Estonian official reserves amounted only to 45% of the short-term foreign debt, which is the level of security), and a high level of deficit in the current account, it constituted serious threat symptoms to the economic balance of the country. In the period when the economic growth rate exceeded the potential rate, the monetary authorities of Estonia were unable to raise interest rates in order

18-19 June 2015, Economics and Finance**

to reduce the risk of inflation. Furthermore, the increase in inflation caused a decrease in real interest rates, which further intensified the economic expansion. However, in the situation of the recent financial crisis and economic downturn, which Estonia had to deal with, the monetary authorities of the country were deprived of the possibility of lowering interest rates to reduce the risk of recession. Therefore, the economic collapse occurring in Estonia from the third quarter of 2008 to the first quarter of 2010 was largely compounded by limitations of the monetary policy related to the use of the currency board system. The Estonian economy experienced the deepest economic crisis since the early 1990s. The decrease in the GDP volume reached more than 15% in the first, second and third quarters of 2009.

One of the most important consequences of the crisis - as it turned out, paradoxically positive for Estonia - was the decline in inflation rates. In Estonia, which had a two-digit rate of inflation before the crisis, i.e. one of the highest in the region, as a result of the global economic downturn observed a rapid disinflation process, sometimes turning into deflation. The drop in the general price level in Estonia continued from May 2009 to February 2010, which enabled the country to meet the criterion of price stability. Meeting this convergence criteria, which could not have been achieved in a period of high economic growth, was only possible due to the deep economic slump (Żuchowska, 2011, pp. 23-25). The situation of the public finances in Estonia was highly stable and despite a significant decline in the economic activity during the global crisis, the country had the lowest level of domestic debt of the agencies of the central and local governments throughout the EU. The public finance discipline enabled Estonia to meet the remaining economic convergence criteria in 2010.

Conclusions

The conducted analysis enabled to draw the following conclusions:

Firstly, the experience of the analysed economies show that the currency board system is effective in the early years of its use, helping to control hyperinflation and stabilising the economy. In the longer run, however, it turns out to be inefficient. This is related to the problem of time inconsistency, i.e. the solutions which are optimal in a given time, at a certain moment become a source of serious problems themselves in the economy.

Secondly, all the analysed economies suffered the risks associated with the use of a currency board system, as indicated in the theory. Thus, these

18-19 June 2015, Economics and Finance**

concerns do not arise from the specific conditions of the economy, but the essence of the solution of the rigid exchange rate.

Thirdly, as shown in the analysis of the case studies, the biggest cost of the implementation of the currency board system is losing the ability to run an autonomous monetary policy, which allows the central bank to act counter-cyclically. This is a disadvantage in both good times and in the times of the GDP drop. In the case of external shocks it prevents the recovery of the competitiveness of the economy through its impact on the level of real interest rates. It is because in the conditions of a rigid exchange rate regime, it is not possible to adjust the side of the exchange rate, so costly adjustment on the side of the labour market and GDP follow.

Fourthly, the experience of Argentina and the Baltic states have shown that the adopted exit strategies from a currency board system were very expensive. Argentina suffered a very high cost of floating exchange rate. Lithuania and Estonia took the risk of the transition from the currency board to the monetary union, without the introduction of more flexible intermediate exchange rate solutions. These economies had serious problems with meeting the convergence criteria, especially the inflation criterion, the source of which was the currency board system.

Appendix

Table 1. Meeting the convergence criteria by Lithuania

Criterion	Date of the convergence report	Reference value	Lithuania
Inflation rate (HICP) (%)	X 2004	2.4	-0.2
	V 2006	2.6*	2.7*
	V 2008	3.2*	7.4*
	V 2010	1.0*	2.0*
	V 2012	3.1*	4.2*
	VI 2014	1.7	0.6
Long-term interest rates (%)	X 2004	6.4	4.7
	V 2006	5.9	3.7
	V 2008	6.5	4.6
	V 2010	6.0*	12.1*
	V 2012	5.8	5.2
	VI 2014	6.2	3.6
Budgetary situation (% of GDP): deficit (-), surplus (+)	X 2004	-3.0	-2.6
	V 2006	-3.0	-0.6
	V 2008	-3.0	-1.7
	V 2010	-3.0*	-8.6*
	V 2012	-3.0	-3.2
	VI 2014	-3.0	-2.1
Public debt (% GDP)	X 2004	60.0	21.4
	V 2006	60.0	18.9
	V 2008	60.0	17.0
	V 2010	60.0	38.6
	V 2012	60.0	40.4
	VI 2014	60.0	41.8
Stability of the rate		At least two years of the ERM II; No devaluation to the euro	ERM II since 28.06.2004

* unmet criterion
