Polish Economic Society

The Polish Economic Society (Polskie Towarzystwo Ekonomiczne, PTE) is an independent national association of economists. It was established in 1945 and continues the tradition of the Warsaw Association of Economists and Statisticians and Economic Societies operating in Cracow, Poznan and Lvov before World War II.

At present the Society has 6000 ordinary members and about 220 supporting members (firms, financial institutions, banks). It consists of 24 autonomous regional Branches, whose activities are co-ordinated by the National Board. The Polish Economic Society is a member of the International Economic Association and maintains broad international contacts. The Society's principle aim is to contribute by its activities to the development of economic thought and culture in Polish society.

This is reflected in the following statutory objectives:

1. To disseminate economic ideas and support the creation of favourable conditions for the development of the science of economics and the presentation of their achievements.
2. To promote economic knowledge and dissemination of economic culture in society.
3. To enhance the qualifications of economists in their various areas of professional speciality.
4. To initiate and support activities aimed at social, economic and regional development of the country in an environmentally friendly manner.
5. To seek the integration of economists representing academic science as well as business activities.

Institute of Economic Research

Institute of Economic Research is an independent institution involved in research and popularization of the results of scientific research in the field of economics.

The statutory aims of the Institute are:

1. promoting and supporting the socio-economic development of Poland;
2. Increasing economic awareness of the society and spreading economic culture in the Polish society;
3. Supporting the conditions for the development of Economics and promoting achievements of economists in Poland and abroad;
4. Supporting professional development of economists;
5. Promoting integration and cooperation between academic economists and business.

The Institute's work is focused on supporting scientific research by activities of scientific publishing house, collaboration in the publication of two scientific journals in Economics (*Oeconomia Copernicana* and *Equilibrium. Quarterly Journal of Economics and Economic Policy*), realization of research projects and organization of scientific conferences. In pursuing its objectives, the Institute collaborates with Polish and foreign universities and research centers.

**Economic Policy – State versus
Market Controversy***

JEL Classification: *E61*

Keywords: *economic policy; 'market-centric' model; role of the state; and economic governance*

Abstract: There was wide ranging debate in the 1950s and 1960s in the developing countries about the role of the state in their economy when these countries attained independence, with developing their economies and eradicating poverty and backwardness being seen as their key priority. In the post-World War II period, the all-pervasive 'laissez-faire' model of development was rejected, because during the pre-war period such policies had failed to resolve the economic crisis. Therefore, Keynesian interventionist economic policies were adopted in most of these countries.

This is a theoretical paper, which is based on review of published papers in the field of economic policies, especially about the debate of the role of the state and market. In this study a wide range of sources of data are presented, which includes statistics generated by a number of organisations that are not agencies of a particular government. This is useful since data are compiled by a wide range of organisation such as IMF, World Bank and WTO. Secondary data would help our study to answer the research questions. There seems to be greater potential for examining

* The author would like to thanks Anne White, Hugo Radice and Phil Armstrong for suggestions and comments on an earlier version of this paper. I also would also like to thank anonymous referee for helpful comments.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?

statistical data produced by various organisations that are relatively independent of the national government.

The study finds that more than two decades of pursuing neoliberal policies has reduced the progressive aspects of the state sector. The on-going crisis in terms of high unemployment, poverty and inequality provides an opportunity to critically reflect on past performance and on the desirability of reviving the role of the state sector in a way that will contribute to human development.

Introduction

This paper examines the role of the state and the market in the economic policy in developing countries. Following World War II, the all-pervasive ‘laissez-faire’ model of development was rejected, because during the pre-war period such policies had failed to resolve the economic crisis. Therefore, Keynesian interventionist economic policies were adopted, and North America and the western European countries witnessed a long, uninterrupted phase of growth, often referred to as the ‘Golden Period’ of capitalism. State intervention was seen as the only possibility way to avoid the market failures of the past.

During the 1970s and 1980s, as the economic crisis began to bite hard in the US and the UK, neoclassical economists gained new respectability. They advocated a greater role for the market by reducing the state’s role in areas such as the labour market, supporting privatisation of state enterprises, and the removal of price and interest rate controls (Harcourt, 2014; Little, 1982).

More than two decades of pursuing these neoliberal policies has reduced the progressive aspects of the state sector. The on-going crisis in terms of high unemployment, poverty and inequality provides an opportunity to critically reflect on past performance and to consider the desirability of reviving the role of the state sector in a way that would help contribute to human development.

This study will briefly examine the industrial policies previously adopted by developed countries in addition to their more recent experiences of state intervention. This issue merits discussion because the role which the state plays in setting economic policies impacts on levels of employment, income, education, the standard of living and, most importantly, national sovereignty. The major financial crisis of 2008 has generated conditions which prompt a reassessment and consideration of alternatives to the status quo.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

Throughout the years of the Great Depression, debate continued between Keynes and Hayek. During the post-war period of reconstruction, the Keynesian model was adopted by western governments but with the arrival of the economic crisis in the 1970s, neoclassical economists gained new importance and their recommendations were adopted by the US and UK governments as an alternative way out of the crisis.

Neoclassical or neoliberal economists such as Friedman, Hayek, Krueger, and Little, strongly opposed state intervention, on the grounds that the state was not an impartial agent but led by politicians and bureaucrats who faced constant pressure from interest groups. This led to the introduction of various forms of regulatory laws, which ultimately resulted in increased corruption, red tape, and rent seeking (Little, 1982; Hirschman, 1982; Krueger, 1974).

By focusing on corruption, favouritism and other forms of self-seeking behaviour, the neoliberal economists highlighted how a government with 'good intentions' was, in reality, controlled by special interest groups. Therefore, they advocated a minimal role for the state, arguing instead that it should be left to price mechanisms in the competitive market to decide what should be produced and in what quantities. Their model completely shifted the focus from 'getting the policies right' to an overriding concern with 'getting the price right'. The IMF and the World Bank accepted their recommendations and imposed 'Structural Adjustment Programmes' on developing countries to increase the role of the market, putting pressure on governments which were seeking loans to adopt these policies (Siddiqui, 1994a).

In the past, governments intervened in business affairs, frequently correcting market failures, which is now seen by neoliberals as futile and even wasteful behaviour. Therefore, a critical approach is required to understand the role of the state in the economy in the 21st century which draws on the past experiences of both the developed and developing countries. Lessons may be learnt from this that could be of specific benefit to developing countries, enabling them to build manufacturing sectors which could in turn, ultimately help to reduce unemployment and poverty, and also address environmental issues.

This paper is organised as follows: The opening section provides the background to this topic, outlining the key issues to be addressed and their importance in the 21st century. This is followed by an overview of the 'market-centric' model and an examination of the past experiences relating to industrial policies in the developed countries. The focus then shifts to the

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

issue of state intervention and industrial policies in the developing countries and the East Asian countries, highlighting some key aspects of this continuing debate. The study concludes by making the case for a reconsideration of the role of the state in the economic affairs of the developing countries.

The methodology to be followed here is derived from the aims of the study. This engages an understanding of the issues in the research project. The research question requires international comparisons statistics and provides the main source to answer the research questions and address the objectives of this paper. Analysing the secondary data which has already been presented is the only possible way to get macroeconomic data. The secondary data sets together provide quantifiable information and statistics published by the governments for their country. Country based multiple source data sets are also available from governments' publication and international organisations. These include data such as IMF, World Bank, OECD and UNCTAD statistical data collected for member countries.

Analysing existing secondary data offers the prospects of being able to explore research questions of interest to our study without having to go through the process of collecting. It also offers the opportunity of being able to employ high quality data sets that are based on large macroeconomic data.

'Market-Centric' Economic Theory

Following the economic crisis in the early 1980s in North America and Europe, the 'market-centric' paradigm re-emerged as a viable alternative to neoclassical economic theory. Let us briefly examine its key elements. Neoclassical economic theory emphasises that the market is an ahistorical phenomenon which functions as some sort of universally applicable mechanism for the efficient allocation of resources. Neoliberals visualise the market as socially 'neutral' and human beings as selfish (Little, 1982). They reject any limits to the free market and insist that voluntary actions in the market sphere are inevitably harmonic, peaceful and mutually beneficial for the whole society (Hirschman, 1982; Krueger, 1974). However, market failures can be witnessed in areas such as education, the environment and pollution.

State regulation can be widely seen in the setting of taxes and tariffs and in the regulation of the macroeconomic dynamics of the system of finance and credit. Regarding the role of the state in economic affairs, Thomas

**Proceedings of the 8th International Conference on Applied Economics

18-19 June 2015, Economics and Finance**

Friedman argues: “The hidden hand of the market will never work without a hidden fist – McDonalds’ cannot flourish without McDonnell Douglas, the builder of F15. And the hidden fist that keeps the world safe for Silicon Valley’s technologies is called the US Army, Air Force, Navy and Marine Corps” (Friedman, 1999, p. 373).

The neoliberals insist that the state and public sectors are inefficient and only markets and the private sector are capable of creating growth, employment and human welfare. But in reality, for the last three decades, neoliberal policies have resulted in largely benefitting financial capital, monopolies, and the very rich. Working people and the rest of society witnessed a rise in joblessness, poverty, stagnation or a decline in wages, and cuts in welfare payments. Austerity has added to the misery of the majority by shrinking the public services on which people depend.

By focusing exclusively on the market, which is said to epitomise freedom and equality without also concentrating on the social relations inside the production system, renders the effect of the market system and the broader economy invisible. The idea of the market economy was a set of policies intended to force people to accept market discipline, meaning they had to adjust their economic and political life to the dictates of the market (Perelman, 2011). Neoliberal ideas have become instruments for explaining, legitimising and controlling workers within the market system.

Neoclassical economists assume that ‘in the beginning was the market’ (Williamson, 2003). The model also assumes that markets are perfectly competitive. The market is seen as something which naturally existed from the very beginning of human civilisation. They argue that the state, on the other hand, should be seen as man-made, an idea which emerged as society itself evolved. Contrary to their beliefs, however, economic historians have found there were no markets in the beginning, except those which operated at a very local level to supply the most basic necessities; markets were not important nor did they play a key role within ancient communities.

The neoliberal model does not take into account the social relations of production and disregards the well-being of workers. It is the marriage of macroeconomics with the individualistic-driven market economy. The market is being used to create a fear of losing employment, reducing wages to further power the corporations. The emphasis on efficiency at micro level and on market-based explanation is unable to explain the structural inefficiency which leads to the enormous waste of resources (Perelman, 2011).

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?

Today's developed countries pioneered and relied on state interventionist policies for their industries and trade during the early stages of their industrialisation. Moreover, well-designed interventionist policies in the developing countries have not only been impressive with regard to their performance but overall have fared better in relative terms with their developed counterparts at comparable stages in their development. This is not to claim that state intervention always works. If we consider, for example, the most recent experiences of the industrial policies followed by East Asian countries, these were based on interventionist policies, except in the case of Hong Kong, previously a British colony. Dramatic growth rates were formulated and applied with the state actively promoting industrialisation in the early 1950s (Wade, 2004).

Neoclassical theory rests on the mistaken premise that markets and politics are always autonomous; they are not autonomous as neoliberals claim, but are linked and mutually dependent. The growth of private enterprise does not take place in a vacuum. It requires government support for an environment conducive to price mechanisms and the appropriation of surplus and investment to develop.

Bhagwati (1982) argues that, irrespective of the possible genuine intentions on the part of the government, interference with the economic functioning of private enterprises can create incentives for rent-seeking behaviour. Even when there are market failures, this can make things worse by shifting resources from productive to unproductive activities. On the question of market failure, Chang argues that, "the same market could be seen as failing by some while others regard it as normally functioning, depending on their respective theories of the market [...] Many people think that one of the biggest 'failures' of the market is its tendency to generate an unacceptable level of income inequality" (Chang, 2002, p. 544).

Ian Little (1982), another neoclassical theorist, has argued that a micro-economic approach, which relies on profit and growth maximisation at firm level, will be able to outperform and be more efficient than state intervention, because the latter will be based on wholly insufficient information. Like other neoclassical economists, Little(1982) has stressed there is bound to be a significant discrepancy between the intended official policies and their implementation due to the self-seeking of the bureaucracy (Hirschman, 1982).

A non-competitive market is seen as a failing market by the neoclassical economists, but others, such as Schumpeter, accept that the existence of a non-competitive market is an inevitable feature of a successful capitalism

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

(Goldsmith, 1995). The issue of perfect information is seen as necessary for a competitive market to exist and may lead to the diffusion of new technology, which may, in turn, mean no incentives for entrepreneurs to innovate with new technologies. Certain environmental regulations and minimum wages have often been criticised as interference in business freedom and adding to business costs but nowadays regulations concerning factory pollution standards and safety in the work place are hardly seen as intrusive policies.

The outcomes of neoliberal policies in terms of socio-economic variables indicate that in the US and the UK the benefits of such growth have disproportionately gone to the top income groups. For instance, since the adoption of neoliberal policies, both these countries have witnessed growing disparities in incomes and wealth, and this rise has been accompanied by shifts in wealth from wages to capital, cheaper imports and the relocation of some manufacturing industries to cheaper cost countries, squeezing wages further and curtailing the power of unions in the Western countries. Neoliberal policies have created wealthy financial centres in big cities such as New York and London, while the traditional manufacturing areas have suffered from low investment and high unemployment (Wade, 2009; Stiglitz, 2006).

State, Free Market and Economic Governance

It is useful here to briefly trace the links between state, market and economic governance in the past. The state's role in providing guidance and playing a leading role in economic policies in Britain and US, for example, was originally very different to how it is currently portrayed. When developed countries such as Britain and the US were laying the foundations for the modern manufacturing sector, the state was very active in promoting and protecting domestic business interests against those of foreign companies. In fact, in the early phase of their industrialisation, most of today's developed countries adopted industrial policies which were very proactive, and certainly not 'open door' policies of the type now recommended to developing countries. For example, Britain had protectionist policies in place when it was trying to catch up with Holland, which had more advanced industries than Britain (Chang, 2007).

For example, the Corn Laws in Britain, which had protected farmers since the 13th century, were finally repealed in 1846. Over the next two decades, most of the import tariffs were removed (Polanyi, 1957). There is

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

also evidence that the British government intervened in establishing industries: “During the early phase of Britain’s industrial development, Robert Walpole, the British Prime Minister in 1721, launched an economic policy to transform the country from an exporter of raw material into an industrially developed nation. He sponsored legislation directed towards protecting domestic industry from foreign competition and export companies, supported through export subsidies. Moreover, import tariffs were raised on foreign goods, while import tariffs on raw materials were removed to make imports cheaper for the country’s export industry. Walpole’s policies were not those of a “free market”. Instead his government provided heavy protection and subsidies to infant industries” (Girdner and Siddiqui, 2008, p. 9). Only after the Industrial Revolution was well established did the government open up domestic markets to foreign completion.

The British Crown granted monopoly status to their companies and also made treaties with foreign governments to obtain exclusive trading privileges for them (Polanyi, 1957). At the same time, the government put up import taxes and paid subsidies to domestic manufacturers: “The [British] East India Company and other companies chartered by the monarchy opened markets around the world to British goods. Other grants of monopolies were designed to encourage new industries from abroad to start up in Britain. For instance, the Navigation Acts, once calling them ‘perhaps, the wisest of all commercial regulations of England’ because they promoted national defence’ [...] The net effect of British mercantilism was to nurture companies that, when *The Wealth of Nations* appeared, were strong enough to exploit new markets and new technology, making England the workshop of the world” (Goldsmith, 1995, p. 645).

Thus, the state initially played a defining role in Britain in the development of the market economy, rather than this having naturally existed as assumed by the neoclassical theorists. As Polanyi has argued, “The road to the free market was opened and kept open by an enormous increase in continuous, centrally organised and controlled interventionism. To make Adam Smith’s ‘simple and natural liberty’ compatible with the needs of a human society was a most complicated affair. Witness the complexity of the provisions in the innumerable enclosure laws; the amount of bureaucratic control involved in the administration of the New Poor Laws which for the first time since Queen Elizabeth I’s reign were effectively supervised by the central authority [...] new powers, organs, and instruments required for the establishment of laissez-faire (Polanyi, 1957, p. 140)

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

In the US, too, state intervention was seen at the time as the best available policy tool to establish property rights, facilitating the provision of infrastructure such as the railroads, and even the success of early industrialisation. Right up until the beginning of World War II, the US had a heavily protected economy. For example, it had by far the highest tariff rates among the Western countries for most of the 19th century when its average tariffs rates were approximately 40%, while those of Austria, Belgium, France and Sweden were no more than 20% during the same period.

The first Secretary of the US Treasury, Alexander Hamilton (1789-95), set out a clear strategy concerning how the country should develop an industrial base in his *Reports of the Secretary of the Treasury on the subject of manufactures* (Chang, 2007). It is well-documented that in the past, the state was clearly involved in creating the conditions for industrial development (Girdner and Siddiqui, 2008). It is well known that infrastructure plays a crucial role in economic development and, therefore, the government should take a lead in making investments in infrastructure. For example, the US government took the responsibility for investing heavily in infrastructure such as railroads and telegraph lines, due to their high costs and long gestation periods. During the latter half of the 19th century, millions of acres of land were made available by the government for these tasks. Education was another area which was seen as too important to be left to private initiative alone. For instance, schooling was made mandatory for the first time in 1852 by the state of Massachusetts. Soon other states followed, because it was considered that businesses often chose to invest too little money on their employees' skill development; it was also feared that if workers could leave any time, they would ask for higher wages to stay (Polanyi, 1957).

The National Banking Act of 1863 was the first US bank regulation to provide a stable financial system and currency, which assisted the business sector (Polanyi, 1957). The state also took the lead in investing in the education sector to improve the general skill level within the country. The US government involvement in agricultural R&D began in Connecticut in 1875 where the government funded research into hybrid corn; a further breakthrough came from a government-funded research laboratory in 1917 with new seeds producing a higher yield. This was soon spread to other states; the government also provided financial incentives to farmers (Chang, 2007; Polanyi, 1957).

Similar state intervention policies were part of the official policies in 19th-century Germany, too. In the 1840s, a German academic, Friedrich

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

List, argued that his country firstly needed to build a successful manufacturing sector and only then would it be able to follow ‘free trade’ policies. He concluded that “in order to allow freedom of trade to operate naturally, the less advanced nation [Germany] must first be raised by artificial measures to that stage of cultivation to which the English nation has been artificially elevated” (List, 1966, p. 131). Similarly, Japan later followed state intervention policies to strengthen its industrial base against foreign competition. As Cowling and Tomlinson’s (2011) study concludes: “The Japanese case also demonstrates that, with a degree of protectionism, industrial strategy and state investment can deliver dynamic growth for a (significant) period. However, in the long term, Japan (and Russia) also highlight that where a corporatist policy is pursued and hierarchical governance structures emerge, then long term development paths are likely to be determined by the few with the public interest being compromised” (Cowling and Tomlinson, 2011, p. 843). In short, in almost all present day developed countries state intervention was seen as the best-option policy to establish the manufacturing sector and it played a key role in their economic development and sectoral transformation.

The Role of State in the Developed Countries

The passion for the ‘free market’ has emerged from various sources, beginning with Adam Smith’s ideological premise that by means of market forces each individual’s free and selfish pursuit of gain will be transformed as if by an invisible hand to achieve socially optimal results. It is worth revisiting Adam Smith’s ideas, since they are so often quoted by neoclassical economists to support their laissez-faire policies. Other economic theorists, such as Amartya Sen (1999), strongly support the role of the state, especially in areas of social responsibility including health care, education and other welfare measures, and the maintenance of adequate levels of employment. Sen attempts to combine Adam Smith’s economic ideas with moral philosophy (Smith, 1976), noting, for instance, that Smith acknowledges that the government has an important role to play, namely, “the duty of erecting and maintaining certain public works and certain public institutions” (Smith, 1937, p. 651). These public goods include provisions to accumulate and encourage the development of technology and education, both of which can be expected to contribute positively towards raising the productivity and wellbeing of society.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

It is argued that the private sector does not have the necessary resources to provide sufficient social capital by itself. As Adam Smith points out, these tend to be assets “which it can never be for the interest of any individual, or small number of individuals, to erect and maintain; because the profit could never repay the expense to any individual or small number of individuals, though it may frequently do much more than repay it to a great society” (Smith, 1937, p. 862). He argues that Law and Order, property rights and the re-enforcement of contracts prepares the ground for market exchange to take place. He suggests that the government can act as a referee in various contract disputes, which could be prerequisites for market-based resource allocation (Goldsmith, 1995).

The assumption is that the state should serve as a rational actor for the benefit of society as a whole i.e. in the interests of the common good. Broadly speaking, the main arguments in favour of state intervention seem to centre on five areas: 1) the re-enforcement of property rights, contracts and procurement of institutions for production and exchange; 2) macroeconomic policies; 3) procurement of infrastructure and provision of public services, such as health and education, 4) operational control over private companies, and 5) participation in the production of goods and provision of services.

State intervention in economic policies was adopted by Britain, the US and Germany during the 19th century. Whilst in Britain and the US, the state remained in the background but continued to play a crucial role, in Germany the state’s role in policy initiatives to build the domestic manufacturing sector was very visible and it successfully managed to transform the economy during that period. Later, in the 1950s in Korea and Taiwan, the state played a crucial role in issues including land distribution, construction of infrastructure, and industrialisation whilst during in the 1980s in China, the ‘revolution from above’ state played a more active role in supporting domestic industrialisation (Chang, 2007; Wade, 2004; Amsden, 1989).

Rather than prematurely opening their industries to foreign competition, other western European countries followed Britain’s lead as soon as their industries were strong enough to compete. However, the neoclassical economists choose to ignore these historical facts, and deny governments a role in formulating industrial policy in the developing countries.

In recent years, there has been growing dissatisfaction with the neoliberal paradigm (i.e. free-market) that has dominated economic policy over the last few decades. In fact, in the early 1980s, the so-called ‘Washington

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

Consensus' emerged which included the promotion of policies such as the free-market economy, de-regulation, privatisation, and trade and capital liberalisation. These were widely backed by international financial institutions, including the World Bank and the IMF, and the British and US governments (Williamson, 2003; Siddiqui, 1994a). Such policies have increased corporate power and this dominance of the corporate sector and the economic crisis that have followed have led many to question the relevance of such policies and seek alternative policies for the 21st century (Narcis and Stiglitz, 2009; Fine *et al.*, 2003).

According to Mohanty and Miraglia (2012) although neoliberalism "inevitably places capitalist interests above the needs and hopes of the people, it is the people's movements (anti-colonial/anti-imperial, peasant, ecological, labour...) that have exposed the faults-line of neoliberal capitalism and placed questions of democracy, equity and justice at the centre of the struggle for emancipation" (quoted in Harcourt, 2014, p. 1308).

There is an on-going debate concerning the role of the state in economic policy measures between those who favour state intervention in designing economic policy and the neoliberals, who will not countenance any economic intervention by the state. Some of these issues involve the design and implementation of public policies aimed at improving the economic well-being of citizens by fostering economic development and preventing crises. The interventionist argument has its origins in the early period of capitalism in Britain, when some defended protectionist policies and monopoly concessions granted by the government in the 16th and 17th century. Later, however, in the 18th century, the continuation of such policies was opposed by Adam Smith who favoured free trade and laissez-faire capitalism. However, in the 19th century, with the exception of the UK, all the major European countries and the US followed protectionist policies, employing active state intervention to protect their domestic industries against foreign competition (Chang, 2002).

Any comparative analysis of economic performance requires the analysis of a longer period of data. For example, between 1945 and 1980, the western European economies recorded higher growth rates than the US. A closer examination of the state role in the US economy since the mid-1990s provides some interesting facts. For during that period, despite assigning a major market role to the crucial sectors of the economy, the state continued to play a leading role in both the decimation and the development of research and innovation, often through state-controlled defence industries (Kitson, 2005). Cowling and Tomlinson (2011, p. 847) conclude that "wid-

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

er public interests are likely to be better served through an inclusive approach where governance structures are relatively diffuse and allow opportunities for all stakeholders to participate in the development process”.

In the developed economies state ownership can be vast. For instance, in the much celebrated free enterprise of Singapore, the land is fully owned by the state and also about 85% of the housing is provided by the state. Also more than 20% of the Gross National Product (GNP) is produced by the state owned enterprises in Singapore (Siddiqui 2010b), whilst in the UK, the public sector National Health Service is still the largest employer. The state plays an important role in most countries by providing backing for the monetary and credit system. Certain public goods such as street lighting should be provided from public expenditure. The procurement of infrastructure and the provision of public services are based on the notion that these are the necessary preconditions for economic growth and social progress. The private sector would be unable to produce by itself. For the proper functioning of contemporary economies, it is widely acknowledged that areas such as mediation, contract and regulation can assist the market.

Role of the State in the Developing Countries

The neoclassical model of economic development suggests the primacy of the market as a means of improving the standard of living and income in the developing countries (Little, 1982). Top economic experts and financial officials from all the Latin American countries, except Brazil, were trained in the neoclassical tradition in the US in the 1980s and were assigned to oversee the implementation of the IMF’s prescriptions after the debt crisis. These countries mostly focused on macroeconomic stabilisation programmes including privatisation of state enterprises, trade liberalisation and restricting the role of the state in the economy (Siddiqui 1994b). These governments had no inclination to learn from the East Asian experiences of the recent past. They saw the state as the source of all ‘distortions’ and associated this with the failure of their own previous ‘import substitution’ policy (Amsden, 2009a).

Neoliberal economists say that the invisible hands of the market are the best allocating forces to bring about rapid growth. Economic developments are regarded as best driven by private enterprises with little or no state intervention (World Bank, 1993; Little, 1982). Latin America’s ‘import substitution’ policies were blamed for producing inefficient, rent-seeking behaviour, slow growth and macroeconomic imbalances. Another proponent

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

of neoliberalism, Deepak Lal (1983), is highly sceptical about the role of the state in the government of developing countries. According to him, “many developing countries are closer in their official workings to the rapacious and inefficient nation-state of 17th- or 18th-century Europe, governed as much for the personal aggrandizement of their rulers as for the welfare of the rule” (quoted in Wade, 2004, p. 10).

Latin American governments began to embark on interventionist policies in the 1930s, their aim being to encourage and lay the foundations for domestic industrial development. By encouraging a policy of ‘import substitution’, domestic producers would develop the capacity to produce goods that would otherwise be imported. High tariff rates discouraged imports, while subsidies and local demands encouraged domestic producers. This policy was rooted in populist movements led by individuals such as Perón in Argentina, Cárdenas in Mexico, and Vargas in Brazil. This strategy was initially successful in developing an industrial base in countries such as Argentina, Mexico and Brazil, but in the 1970s, such policies began to experience crisis (Shapiro and Moreno-Brid, 2014).

Moreover, these countries generally relied on imports of new machinery and technology and also capital investment by multinational companies (MNCs). In Brazil, MNCs accounted for 44% of all domestic sales in 1965, while domestic private and public companies together accounted for the remaining 56%. By 1972, MNCs controlled more than half of the total manufacturing investment in both Brazil and Mexico. By the mid-1970s, this model had entered deep crisis with public sector management and the growth of vast bureaucracies encouraging corruption. By the late 1970s, these countries faced chronic financial difficulties, particularly with balance of payments deficits.

Since Latin America’s exports consist of naturally based products, these sectors have limited potential for productivity growth and technological upgrading. In 2012, just ten commodities and mineral products including coffee, soya beans, sugar, fruit, iron ore, copper, gas and oil, accounted for more than 40% of Latin America’s total exports: “In Mexico, Latin America’s alleged success story in reorienting domestic production to foreign markets, high-tech manufactured goods do represent more than 80% total exports. However, a vast number of these exports are essentially produced in maquiladoras that locally assemble imported inputs with scant use of domestic intermediate products or raw materials [...] in reality, they are high-tech exports produced through rather simple assembly process that neither rely on local R&D capacities nor have significant backward or for-

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

ward linkages with domestic suppliers” (Shapiro and Moreno-Brid, 2014, p. 193).

It seems that the governments in Latin America equated export promotion with trade liberalisation and deregulation, and their industrial policies were abandoned and their fiscal policies to promote competitiveness of selected industries were dropped. The liberalisation and open-market policies which they adopted in the 1990s were supposed to align domestic prices with international prices. This was completely the opposite of what Amsden found in her earlier study of industrial policy in South Korea (Amsden, 1989) where, in the early phase of industrialisation, the prime issue was not to ‘get the price right’, but to deliberately ‘get the price wrong’ (Amsden, 2009b).

In recent years Latin America has improved its terms of trade and experienced a commodity export boom, which has been associated with rising imports from China but it is difficult to predict how long this will continue.

When President Lula came to power in the 1990s, Brazil adopted a long-term developmental policy to promote specific industries. With the help of its development bank (BNDES), the government provided a massive amount of finance to promote a few selected industries in the country. As a result, a number of Brazilian companies emerged in the 2000s as internationally competitive. For example, Petrobras emerged as a leading company within the oil and petrochemical sector, not only in Brazil but also internationally, an achievement which was made possible due to massive state support. In contrast to this, Mexico’s government decided to scale down the role of the development bank in assisting and financially supporting other key domestic industries. For example, the investment potential of Pemex was severely affected due to this government decision; similarly government policy measures were taken to withdraw the support previously extended to Nafinsa and Bancomex (Shapiro and Moreno-Brid, 2014).

The economic crisis in the developing countries in the 1980s and 1990s provided an opportunity for international financial institutions to impose ‘Structural Adjustment Programmes’ in the name of aid, which has since proved disastrous (Siddiqui, 2013). To cite but one example, Stiglitz found that the market liberalisation process led to foreign investors increasing their control over African resources rather than assisting them towards long-term independent development. Moreover, these policies brought further cuts in public spending in the health and education sectors (Siddiqui, 2014b), leading to further deterioration in the availability of these vital

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

services which has impacted most negatively on the poor in the developing countries (Stiglitz, 2006).

The question arises, then, as to why the state is once again playing a leading role in South Africa's power sector, and why a similar situation can be found in some Latin American countries. The experience of South Africa's power sector represents an interesting case in which the 'standard model' of competition and privatisation was seriously considered due to pressure from the World Bank but was soon rejected.

Eskom, the South African electricity supply company, remains state owned: "Eskom has led an impressive national electrification drive. The proportion of households with access to electricity has risen from below 49% in 1993 to nearly 70% in 2003. In the years 1994-2002, 3.8 million new households received electricity [...] Eskom was and continues to be a relatively well functioning public utility. Unlike many other developing countries, which suffer from serious operational inefficiencies, Eskom delivers reasonably reliable and quality power at low prices and it is financially viable" (Eberhard, 2005, pp. 5309-5310).

The electrification programme in South Africa represents a remarkable achievement perhaps without any international precedent, with access to electricity doubling from 33% to 66% of the population in the short period of time from the end of the 1990s to the early 2000s. Facing this challenge was necessary in order to overcome the legacy of the inequalities of apartheid. The South African experience demonstrated that it is possible to make substantial progress in widening access to electricity services for the poorer sections of society who historically have been underprivileged. Although this was achieved by a state-owned enterprise, it was made possible due to technically competent and financially sound and most of all, the state's willingness to support it throughout.

This is particularly important in countries where industrialisation historically began much later than in West European countries. When there is a need to undo historical legacies and backwardness, the state's role can be quite important. The experience of neoliberal reforms in Russia in the early 1990s highlights the dangers of ignoring the issue of governance and of giving greater powers to foreign investors. It is useful to quote Wade here: "Low private saving, dependence on primary product exports, declining prices of exports in relation to imports, small internal markets, limited skills, few entrepreneurs adept at large-scale organisation, and pervasive under employment – required an even bigger role for the state than in the more developed countries" (Wade, 2004, p. 8). In fact, there has been a

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

long history of state intervention to promote innovation and disseminate new technologies, primarily to negate market failure when a lack of incentives for generating new technologies may lead markets to underinvest and they prove incapable of taking the lead in the R&D of technologies.

In the Indian context, it is relevant to cite here the earlier debate between Amartya Sen and Jagdish Bhagwati (Ruparelia, *et al.* 2011). Sen (1999) argues in favour of state intervention in areas such as education and health, claiming that government measures should be a starting point for tackling mass poverty and the other ills that beset India. Bhagwati, however, prefers rapid growth, and assumes that the wealth generated will presumably be utilised later to solve deprivation of various kinds including poverty (Bhagwati, 1982). Sen emphasises the importance of both state and market forces as agents of development, and advocates strong intervention by means of social welfare schemes (Sen, 1999). He believes that food, employment, health and education should be provided through government schemes entailing active state involvement, whereas Bhagwati prefers direct cash transfer to the poor who can choose private or public providers for the services they require. The important issue is that of ecological sustainability. Sen often acknowledges the need to bring environmental regulation into the equation, while Bhagwati largely ignores it. For neoclassical economists, growth is the first priority and they are not concerned about increasing inequality.

For example, the past two decades of higher growth in India were characterised by a net decline in employment in most sectors. Some 93% of India's labour force continues to work in the informal economy without a living wage or any of the benefits or security of formal employment. While the Indian labour force has increased by 100-125 million, employment in the formal economy has grown from a meagre 26.7 million in 1991 to a still meagre 29 million in 2001 (Siddiqui 2014a).

Neoliberalism promotes a market model of development. In education it has already brought about state withdrawal from its wide ranging responsibilities (Siddiqui, 2014b). To follow a liberalisation policy in the agricultural sector in a country with a large population like India could prove catastrophic. For instance, it could lead to land-use shifts from cultivation of grain for domestic consumption to a preference for export crops. As a result, such development could undermine domestic food security (Siddiqui 1999). Sharp fluctuations such as a rise in prices could hurt consumers, while a sharp fall would undermine farmers' incentives to invest in the land

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

and thereby contribute further to slowing down overall economic development (Siddiqui, 2014a).

In fact, neoliberal reforms in developing countries in recent years have weakened the state regulation of the economy and also created the conditions to promote and expand the role of private enterprises and markets (Siddiqui, 2012b). At present, with the increased process of globalisation and integration into global markets, the governments in developing countries are seen reducing taxes and government spending, selling off public companies and minimising the role of the state in economic affairs to foster more individual initiative and business opportunities (Siddiqui, 2012b).

The international financial capital of the 21st century seems to be different in a number of such ways from the past. First, it determines the possibility of Keynesian demand management, which required state intervention to boost levels of domestic economic activity. This means using state intervention to build a productive economic base could prove controversial. Second, under capital liberalisation, the developing countries need to raise interest rates to attract capital and also foreign capital confidence becomes very important. This could lead to higher costs for borrowing, which could discourage investment and reduce aggregate demands. Higher interest rates will also increase costs for small businesses, meaning a further contraction in economic activity. On the other hand, the state will face more fiscal crises due to the increased cost of debt servicing, which cannot be met by raising taxes on the rich and corporate sector, because the open economy will be under pressure to maintain lower tax rates to attract investors and higher taxes would prove to be a disincentive. Moreover, import duties have to be reduced as a part of liberalised economic policy measures. All these further accentuate the fiscal crisis of the state, and as a result the government may have to cut social spending on development expenditure. These could further contract the domestic economy.

State Intervention in the East Asian Economies

The arguments in favour of extensive state intervention have been based around the experiences of historically backward countries, their underdeveloped institutions including markets, and the absence of a strong entrepreneurial class. Malaysia's industrial policy in the recent past offers important lessons for other developing countries. The implementation of its New Economic Policy (NEP) and its successful outcomes require the state to be actively involved in the economy. For example, looking more closely

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

at Malaysia's industrialisation, it is well established that state intervention in the last quarter of the 20th century did help it to diversify and the country was able to build a manufacturing sector. Poverty alleviation and income redistribution was also achieved successfully by means of active state involvement as well as market coordination in an ethnically sensitive country like Malaysia (Siddiqui 2012a).

Furthermore, Rasiah and Shari (2001) point out that from 1970 to 1990 the NEP was applied by providing strong incentives to both 'import-substitution' and 'export-oriented' policies to develop the manufacturing sector. The adoption of NEP during the period of 1970-1990 heralded an era of rapid economic growth, job creation and a rise in incomes throughout the country. Poverty and inequality have declined and the government has been able to address the historical legacy of the ethnic divide between communities which arose largely from the colonial policies of the past. Unemployment was reduced from 8% in 1970 to 2.6% by 1996 (Siddiqui 2012a; Rasiah and Shari, 2001).

There seems to be no doubt that Malaysia's growth and industrialisation strategy throughout the NEP period relied on state intervention, with a coordinated role for both the state and the market. In fact, the poverty reduction measures were launched under the close supervision of the state and the outcome was remarkable. The poverty level was decreased from 49.3% of households in 1970 to 16.7% in 1990 (Siddiqui 2012a).

Rasiah and Shari's (2001) study on the issue of state intervention concludes: "The experience of Malaysia demonstrates the need to formulate effective industrial policies, taking cognisance of the market and the institutions necessary to ensure effective coordination between firms, factor markets and product markets. Through preferential policies, the state expanded *Bumiputera* employment in public services and stimulated their greater participation in manufacturing, thereby succeeding in its efforts to restructure the occupational identification of ethnicity, which was complemented by land schemes and the distribution of shares among poor *Bumiputera* households" (Rasiah and Shari, 2001, p. 75).

China's changes in policies in the 1978 began in the agricultural sector by giving more production (Siddiqui, 2009) and sales responsibilities to households rather than village communes, which ultimately increased output and local participation at village levels, perhaps also allowing some wider participation in decision making. The Chinese government played a key role in all these initiatives, by changing the economic direction of the country in 1978. Later, a more active role in technological upgrading and

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

innovation enhanced the competitiveness of Chinese industries (Siddiqui 2009).

Regarding the question of the export success of East Asian countries, Amsden (2009a) claims it is irrelevant to argue against the ‘import substitution’ and ‘export promotion’ policies. In her study of the East Asian countries, she finds that both policies complemented each other. She further argues that “only one simple story tends to repeat itself: behind the rise of every export was an earlier import substitution investment policy” (Amsden, 2009a). It was argued that free-market and laissez-faire policies enabled East Asian countries to achieve spectacular rates of export growth as a result of the competitiveness enforced by their exposure to the international market (World Bank, 1993). However, contrary to such claims, it is now known that these economies were highly protectionist, dirigiste regimes (Chang, 2002; Amsden, 1989).

The East Asian economies experienced higher rates of growth for more than four decades until 1997 and became developmental success stories thanks to state intervention policies. These countries used government policy to guide the markets.

There has been an acceleration of growth rates in East Asian countries—such as South Korea, Singapore, Taiwan and Malaysia in the 1970s and 1980s, namely in countries who hardly followed neoliberal prescriptions (Siddiqui 2010b). These countries have achieved high rates of economic growth via strong state direction in economic policy matters (Wade, 2004). Moreover, the successful emerging economy also needs to be independent, dealing with their domestic classes whilst also controlling non-state agents. The state also uses power and resources to implement interventionist policies, which runs contrary to the prescription of international financial agencies. Unsuccessful emerging economies pursue interventionist policies but end up failing because they are pressurised by special domestic and international interest groups, and obviously lack relative autonomy. For example, the state played a key role in the development and performance of the Japanese and Korean steel industries and also in building other modern industries such as Korean shipbuilding, cars and electronics; Indian agriculture in the 1960s (Siddiqui, 1999), and its IT sector in the 1990s; Argentina’s finance sector; South Africa’s mining and power sectors (Siddiqui, 2014a). All these were successfully achieved with state assistance (Fine *et al.*, 2013; Amsden, 1989).

For more than two decades, economic policies, particularly those in Latin American and African countries, have been dominated by market-

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

oriented policies. The imposition of neoliberal policies across the developing countries and in the economics profession via multilateral institutions such as the World Bank, the IMF and the WTO together with the Western governments could be clearly seen (Siddiqui, 1994b). In fact, both the debt crisis in the 1980s and the East Asian financial crisis in 1997 served to strengthen the grip of neoliberalism, with policies being revisited rather than dropped. But the IMF's credibility as an institution weakened in developing countries (Siddiqui, 2014b; Stiglitz, 2006).

Conclusions

This study has argued that economic governance is crucial for development since it is associated with the ability of actors to participate in decision-making processes, which have an impact on economic growth, job creation, income, investment and the environment within a country. With the adoption of neoliberal policies, the corporate and financial sector and bureaucrats have acquired increased power in developing countries. It also means that national sovereignty itself is being threatened in the name of so-called growth and market efficiency. Neoliberal reforms in developing countries have led to a reduction in the role of the state whilst market forces have been assigned a correspondingly greater role. Neoliberalism also promoted the interests of the corporate-financial capital on the grounds that what is good for them is good for the nation. Similarly they failed to predict and analyse the 2008 financial crisis, and also provided very little theoretical justification for the interventionist policy measures which were applied at the beginning of the crisis.

More than three decades of experience have shown that far from promoting economic growth, neoliberalism has not succeeded in reducing levels of poverty, particularly in Africa and Latin America, where such policies were launched more than two decades ago. For example, the average annual rise in per capita income in the developing countries has slowed down from 3% during the interventionist period of 1960-1980 to 1.5% during the following two decades 1980-2000. Moreover, the most disturbing fact is that in the poorest developing countries (i.e. those with per capita GDP of US\$ 375-1121), this declined from 1.9% in the first period to just 0.5% during the second period of the neoliberal reforms (Chang, 2002).

We should perhaps then make a concerted effort to dispel the myth that market competition is overwhelmingly a source of innovation and competitive advantage. The truth is that the government plays a huge role as the

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

ultimate risk taker, financier and social coordinator, both between firms and workers, and between firms and the state. The state should engage more in economic developmental and policy matters and that readjustment is required, shifting away from high levels of reliance on the financial sector and market forces towards more sustainable productive activities (Wade, 2009). Industrial policy could broadly include such aspects as support for 'infant industries', trade policies, and policies affecting foreign capital and investment. This means establishing guidelines covering the operation of the market and setting the boundaries between what should be governed by the market and what should not (Wade, 2009; Narcis and Stiglitz, 2009).

In the past the state had a good record of stimulating innovation-led growth, not only by mitigating private sector risks but also taking risks that the private sector would not take. For example, the development of aviation, nuclear energy, computers, biotechnology, and solar energy were all successfully achieved by means of state support. Developing countries require an industrial policy in which the government takes a clear role in leading innovation in renewable energy techniques, public transport, health and education.

The question of the distribution of surplus and the issue of social justice are not recognised in neoliberal analysis as economic issues requiring important consideration.

For neoclassical economists it appears that capital formation as an efficient allocation of resources is not viewed as a crucial factor of development. Once instructional arrangements are in place to generate efficient allocation of resources then investment can take care of itself. Their models totally ignore the historical legacies of underdevelopment, pretending that the past was free from difficulties and trying to blame the current problems on the developing countries themselves.

There are a number of reasons why the neoliberal model is not sustainable. In most of the developing countries, the income distribution was very unequal; therefore, the domestic markets remained highly unequal and were unable to absorb the manufactured goods produced (Siddiqui, 2010a).

The crisis which the developing countries have experienced for more than two decades shows how futile it is to assume that this could be resolved once the primacy of the market had been restored, and that the economy will naturally develop as long as the state does not interfere with its functioning. These claims are false with little if any support from historical precedents. The state should act in the interests of the majority in order to promote overall human development.

Unemployment: Walras's Voluntary and Keynes's Involuntary

JEL Classifications: *B3; C6; D5; E0*

Keywords: *Walras; Keynes; Voluntary Unemployment; Involuntary Unemployment; Aggregate Supply function.*

Abstract: This paper shows that Keynes's involuntary unemployment derived from Walras's voluntary unemployment by means of changing of the characteristic of the aggregate supply curve (function) of labour. When the original aggregate supply function is a strongly increasing function, as in Walras's approach, there might be only voluntary unemployment, and its magnitude is the difference between the available quantity of labour and the equilibrium point. At the other hand, if the supply curve of labour is a weakly increasing, which means that the supply function may has a horizontal segment then there might be involuntary unemployment if the equilibrium point locates between boundary points of the horizontal segment, and the magnitude of involuntary unemployment is the difference between the right boundary point of the horizontal segment and an equilibrium point. According to Walras's approach also might be considered "forced unemployment" which is the result of an intervention of external forces (government, monopoly, trade unions, and so on) into the market, and therefore, it is a disequilibrium phenomenon. Finally, in reality there are many types of labour, hence a suggested comprehensive approach of employment might be a useful tool for policy making and planning of economics.

Introduction

This paper shows that Keynes's involuntary unemployment derived from Walras's voluntary unemployment by means of changing of the characteristic of the aggregate supply curve (function) of labour. On the one hand, it will be shown that Walras's theory allows defining voluntary unemployment, despite of that post-Walras authors have been asserting that Walras economy is characterized by full employment. At the other hand, despite Keynes's vague and incomplete definition of full employment, voluntary unemployment and involuntary unemployment, it provides a theoretical framework for their definition. This paper demonstrates that Keynes defined the following main characteristics of a general definition of involuntary unemployment: (1) *It is an equilibrium phenomenon*; (2) *It may or may not exist, and, if it does, then equilibrium employment is less than the available quantity of the factor*; (3) *It may co-exist with voluntary unemployment*.

Seventy five years ago Keynes coined the term "involuntary unemployment" in his famous *General Theory*.¹ Since then, this central issue of Keynes's economic theory has been assessed in two very different ways. On the one hand, there are economists who consider "involuntary unemployment" to be an innovation, and one of Keynes's crucial contributions to economic science (Shapiro & Stiglitz, 1985, p. 1217). On the other hand, there are those who consider the concept of "involuntary unemployment" as an issue which does not contribute anything to the employment theory and, as such, is superfluous (Pissarides, 2000, pp. xv-xvi). Keynes himself asserted that 'my doctrine of full employment is what the whole of my book is about!' (Keynes, 1996-1960, XIV: 24).

The crucial reason for this bewildering situation in the definition of involuntary unemployment and its use for the policy making is the missing of the line of demarcation between pure theory and applied theory. Some economists deny the existence of involuntary unemployment claiming that in reality it is not possible to find statistical data about it. On the other hand, the reason for the absence of such data might be the above mentioned situation of the definition of involuntary unemployment. So, the theoretical treatment has to be a necessary condition of the practical issues, and there-

¹ The notion "involuntary unemployment" was in use prior to Keynes both by English economists (see Kahn, 1976, pp. 19-20; Ahiakpor, 1998, p. 17) and also by other countries' economists (see Boianovsky & Trautwein 2003). But their notion differs from Keynes's notion.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

fore, this paper will generally consider the theoretical aspect of involuntary unemployment (Walras, 2005, p. 53).

It will be shown that the kind of unemployment depends on the character of the original aggregate supply curve of labour. On the one hand, when the original aggregate supply function is a strongly increasing function, as in Walras's approach, there might be only voluntary unemployment, and its magnitude is the difference between the available quantity of labour and the equilibrium point. So, in such a case, an individual is unemployed according to his own wishes, because an equilibrium wage defined by free competition is less than a wage which he requires. But, at the same time it is incorrect to confuse Walras's voluntary unemployment with leisure. Moreover, unfortunately, some modern economists have been confusing Walras's voluntary unemployment with "involuntary unemployment".

At the other hand, if the supply curve of labour is a weakly increasing, which means that the supply function may have a horizontal segment then there might be involuntary unemployment if the equilibrium point locates between boundary points of the horizontal segment, and the magnitude of involuntary unemployment is the difference between the right boundary point of the horizontal segment and an equilibrium point. So, in such a case, an individual is involuntary unemployed against to his own wishes, because an equilibrium wage defined by free competition is equal to a wage which he requires.

Definition of full employment and the kinds of unemployment is a key issue of the theory of employment. Unfortunately, Keynes's definitions of full employment, voluntary unemployment and involuntary unemployment are extremely vague and incomplete (Hazlitt 1959; Patinkin, 1949, p. 314; Lipsey, et al., 1990, p. 751). These definitions only became murkier as Keynes's followers tried to explain them (*vide infra*).

For example, post-Keynes's economists have been discussing whether "involuntary unemployment" is equilibrium or a disequilibrium phenomenon. There are also two opposite claims, those that claim it is a disequilibrium phenomenon (Clower, 1965, p. 109; Hazlitt, 1959; Mises, 1998, p. 599; Patinkin, 1949, pp. 337-8; Rothbard, 2004, p. 780) and those that claim that it is an equilibrium phenomenon (Davidson, 1967, p. 567; Hahn, 1987, p. 1). In the latter case, the question is whether Keynes's equilibrium theory is equivalent to Walras's one. Unfortunately, Keynes himself alleged that 'Walras's theory and all others along those lines are little better than nonsense' (Skidelski, 1996, p. 615). A majority of economists assert that they are different theories (for example Blaug, Leijonhufvud, De Vro-

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

ey, and Davidson), and unfortunately, only a few economists consider them to be related theories (Morishima 1977; Darity & Horn, 1983, p. 727). It is worthy recalling here Chick's assertion that 'It is doubtful, in fact, whether we would have got in such muddle over Keynes if we had understood Walras properly' (Chick, 1978, p. 20).

The second issue of the employment theory is the interconnection between full employment, voluntary unemployment and involuntary unemployment and their measurement. The point is whether voluntary and involuntary unemployment are mutually exclusive or can they co-exist. The economics literature to date either ignored the co-existence of these two kinds of unemployment or claimed they were both the same (Layard *et al*, 1994, p. 41, 11; Lucas, 1978; Pissarides, 2000; Taylor, 1987).

According to Walras's approach also might be considered "forced unemployment" which is the result of an intervention of external forces (government, monopoly, trade unions, and so on) into the market, and therefore, it is a disequilibrium phenomenon. Unfortunately, Keynes combined Walras's two types of unemployment, voluntary and forced, and called them "voluntary" unemployment. On the other hand, some economists interpreted Walras's forced unemployment as "involuntary unemployment".

The result is that in the economics literature, especially in the textbooks, either there is an abundance of variant definitions of involuntary unemployment or the concept, as well as voluntary unemployment, is not mentioned at all. Therefore, this paper will discuss whether "Involuntary employment" is an innovation or is irrelevant in economic theory.

This paper consists of five sections. Following the introduction, the second section discusses Walras's theory of employment, and shows that Walras defined voluntary unemployment and forced unemployment. The third section considers Keynes's definition of full, voluntary and involuntary unemployment, and demonstrates how Keynes's vague and incomplete definition of these categories causes serious confusion in the theory of post-Keynes's economist. The fourth section deals with the comprehensive approach to employment. Unemployment and Textbook of Macroeconomic is briefly considered in fifth section. Finally, conclusions are presented.

Walras and Unemployment

Walras's general equilibrium approach seems to be "conveniently" characterized by full employment in services included labour. For example, Hayek asserted that: 'But it does mean that we have to start where general economic theory stops; that is to say at a condition of equilibrium when no unused resources exist' (Hayek, 1931-1967, p. 34; see also Madden, 1992; Morishima, 1977, p. 58; Negishi, 1979, p. 17). This is incorrect since Walras's approach assumes that at equilibrium, there might be unemployment of services in Economies: Production, Capital Formation and Credit, and Circulation and Money, and unsold goods in an Exchange Economy (Davar, 1994, pp. 51-2 and 2014b). In order to define unemployment according to Walras's approach let's look at his general equilibrium theory concisely.

First, let's consider the relevant assumptions and definitions in his theory:

1. Walras assumed that the total demand function - as well as demand functions for individuals - is a strictly decreasing function (Walras, 1954, p. 466). The offer function first strictly increases and then strictly decreases. In other words, the offer curve considered first rises and then falls (Walras, 1954, p. 467). Throughout this paper we will assume that the first is the only case.
2. Walras assumed that demand and supply curves for an individual may be either continuous or discontinuous (Walras, 1954, p. 95).
3. Walras determined the effective supply as follows: "We shall apply the term effective offer to any offer made, in this way, of a definite amount of a commodity at a definite price" (Walras, 1954, p. 84). He defined effective demand as: "We shall apply the term effective demand to any such demand for a definite amount of a commodity at a definite price" (Walras, 1954, p. 85). This means that for both demand and supply, for a particular quantity, there is only one price, and vice versa.
4. Consequently, Walras determined the state of equilibrium by comparison of the effective demand and offer of a commodity (Walras, 1954, p. 85).
5. Walras stated that the demand and the offer curves are bounded by an available quantity from above for both the individual and total cases (Walras, 1954, p. 116, 166, 171). This means that, at equilibrium, if it exists, demand and offer always have to be less or equal than the available quantity for all commodities and services.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

Second, let's discuss Walras's method of establishment and re-establishment of equilibrium. Walras employed the common method of equilibrium establishment and re-establishment (variation of prices) in the four types of economies. Namely, he first considered the problem of establishing equilibrium for given basic data for the economy of individual (utility functions for each commodity and services separately, and available quantities of goods and services). Determination of the supply and demand for goods and services for each individual economy is the first step in the random price system. The total supply and demand of goods and services may be calculated from the results of models of individuals' economies. At this stage, Walras formulated two models (equation system) for the equilibrium state and the disequilibrium state, and described the process of establishment of equilibrium by means of the *tâtonnement* algorithm (Davar, 1994, 2002, 2012, 2014b; Negishi, 1985, pp. 170-3). Namely, Walras shows how this iterative process transforms any initial disequilibrium situation to the equilibrium situation if it is possible, and by this, guarantee its solvability. The each isolated iteration of *tâtonnement* is divided into two stages: firstly, equilibrium establishment for a certain good (or service) – *partial equilibrium*; and secondly, general equilibrium establishment for all categories simultaneously – *general equilibrium*. Walras asserted that the partial equilibrium of a certain category would be exist if the essential assumptions (vide supra) plus the additional requirement, that is, the total (aggregate) demand curve and the total offer curve have *at least one intersections point* (Walras, 1954, pp.108 and 171). Walras concentrated throughout on the *Law of Equilibrium State*, which is different from the well-known “Walras’ law” formulated by his followers (Davar, 1994, 2012, 2014). While the Law for more advanced economies only applies to new markets entering the system, it automatically includes the law relating to earlier types of the economy. For example, the Law of Capital Formation and Credit only relates to new capital goods, saving, investment and rate of income. Thus the equilibrium law for consumer goods and services for earlier types of economy (exchange and production economies) is integrated into the law for the economy in question (capital formation and credit).

Moreover, Walras discussed the variation of prices, or re-establishing the equilibrium following changes in the given basic data for an individual or group. This means that, on the one hand, if any individual as supplier of services discovers that in the equilibrium state his services (or goods) are not traded, he might changes his initial data according to the results of ob-

tained equilibrium state. Yet, on the other hand, if any individual as demander of commodities discovers that his demand was not satisfied he also might change his initial endowment. Then, the new process of equilibrium establishment is required.

Walras's Voluntary Unemployment

Under the above assumptions, if there is a general equilibrium we could conclude that there should be at most one equilibrium point for a certain service and good (see Figure 1). If the equilibrium point for a certain service is on the upper boundary point of the supply curve (called the right boundary point in the case of post-Walras authors, who used Marshall's curves, with axes interchanged, namely, quantity on the horizontal axis, and price on the vertical one), that is, the available quantity point, then it *may be said this service is to be fully employed*. But, if an equilibrium point is located below the upper point (left side of the right border point), this indicates unemployment in that part of the service, which is given by the difference between the boundary point (available quantity) and equilibrium point, namely as $(t^0 - T)$. Of course, if we take into account the fact that the total offer for services is based on the solution of the model for individuals, we may conclude that, in such a situation, the individual is "voluntarily unemployed". This is because the wage he or she requires to be employed is higher than the equilibrium wage. In other words, in this situation that depends on a person's contribution to the whole economy, *unemployed means voluntarily unemployed*. It is important to emphasize that Walras's voluntary unemployment is generally confused with leisure. However, the leisure is determined by an individual prior to his arrival to the market, whilst the voluntary unemployment is obtained by market forces.

Thus, in Walras's approach, there would be full employment if the equilibrium point is identified with the upper (right) boundary point (available quantity) or voluntary unemployment if an equilibrium point is under the upper point (to the left of the right boundary point). The magnitude of voluntary unemployment is the difference between the boundary and equilibrium points. It should be stressed that in order to define unemployment of services, if it exists, *the available (existence) quantity of service is required*. The latter was not included in Lange and Patinkin's approaches (vide infra).

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

such restrictions; but it is not impossible' (Walras, 1954, pp. 431-432). Walras discussed this for the three types of services, starting with land-services and then to labour-services: 'If the State established a minimum wage by legislation or if certain private organizations did the same by the use of threats and violence, either a certain number of workers would not be able to sell any labour at all, or all of them would find it impossible to sell as much of their labour as they would like - which has nothing to do with the question whether or not it is of benefit to the workers to work more hours at a lower wage or fewer hours at a higher wage' (Walras, 1954, pp. 432-33).

From the above discussion, the following conclusions may be drawn: (1) at the minimum price (wage), the unemployed part of the factor (labour) may be termed *forced unemployment*, determined as $(t' - T')$; which Patinkin calls "involuntary unemployment", (*vide infra*); and (2) at the maximum price (wage), the unsatisfied demand for the factor is the *forced unsatisfied demand for factor (labour)*, determined as $(T - t)$; which Patinkin calls "involuntary over-employment", (*vide infra*).

In this connection, it is interesting that Friedman's definition of "natural rate of unemployment" is consistent with Walras's voluntary unemployment.

Keynes's Definition of Voluntary and Involuntary Unemployment

Keynes's Definition of Voluntary Unemployment

Keynes started his theory of employment and his book with the central statement: 'The question, also, of the volume of the *available* resources, in the sense of the size of the employable population, the extent of natural wealth and the accumulated capital equipment, has often been treated descriptively. But the pure theory of what determines the *actual employment* of the available resources has seldom been examined in great detail' (Keynes, 1996-1960, p. 4). This means that Keynes, as well as Walras, determined unemployment, first of all, in the general form as the difference between the available quantity minus employed quantity; and then discussed possible various kinds of unemployment.

Keynes considered three kinds of unemployment: frictional, voluntary and involuntary. Throughout the paper it is assumed that "frictional unemployment" means fixed share from the available labour forces, and it cannot influence the discussed issues.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

Keynes considered “voluntary” unemployment as being ‘due to the refusal or inability of a unit of labour, as a result of legislation of social practices or of combination for collective bargaining or of slow response to change or of mere human obstinacy, to accept a reward corresponding to the value of the product attributable to its marginal productivity’ (Keynes, 1936-1960, p. 6). Careful examination of this quotation shows that Keynes, unfortunately, combined Walras’s two types of unemployment: voluntary and forced (vide supra). Such an intolerable combination of two opposite directions creates serious confusion post-Keynes’s authors discussing of unemployment (vide infra). Keynes, however, by this definition of “voluntary” unemployment, declared that his own definition of unemployment (involuntary) differs from those (Viner, 1964, p. 236).

Moreover, Keynes’s definition of full employment includes “frictional” and “voluntary” unemployment (Keynes, 1936-1960, pp. 15-16). If “voluntary” unemployment is only considered according to Walras’s definition (vide supra), then such definition of full employment might have certain reasoning, because in this case each individual is either employed or unemployed by his own wishes. But Keynes also included “forced unemployment”, hence such definition of full employment is not only inconsistent with its practical definition (vide supra), but also creates a mystified situation (vide infra). Therefore, we cannot agree with M. de Vroey’s claim that Keynes considered two types of full employment using the supply curve of labour with the horizontal segment. What de Vroey calls the first full employment is an equilibrium employment, as there is the involuntary unemployment as Vroey indicates himself (Vroey, pp. 8-10).

Keynes’s Definition of Involuntary Unemployment

Keynes began his definition of “involuntary unemployment” with the following statement: *‘Men are involuntarily unemployed if, in the event of a small rise in the price of wage-goods relatively to the money-wage, both the aggregate supply of labour willing to work for the current money-wage and the aggregate demand for it at that wage would be greater than the existing volume of employment’* (Keynes, 1936-1960, p. 15).

Keynes understood that this definition of involuntary unemployment is very vague, so he clarified it further (Leijonhufvud, 1968, p. 94; 2000, p. 18): ‘An alternative, though equivalent, criterion is a situation in which aggregate employment is inelastic in response to an increase in the effective demand for its output’ (Leijonhufvud, 2000, p. 26). He then added two

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

simplified assumptions: '(1) That all unemployed resources are homogeneous and interchangeable in their efficiency to produce what is wanted; (2) That the factors of production entering into marginal cost are content with the same money-wage so long as there is a surplus of them unemployed. In this case, constant returns and a rigid wage-unit, as long as there is any unemployment' (Leijonhufvud, 2000, p. 295).

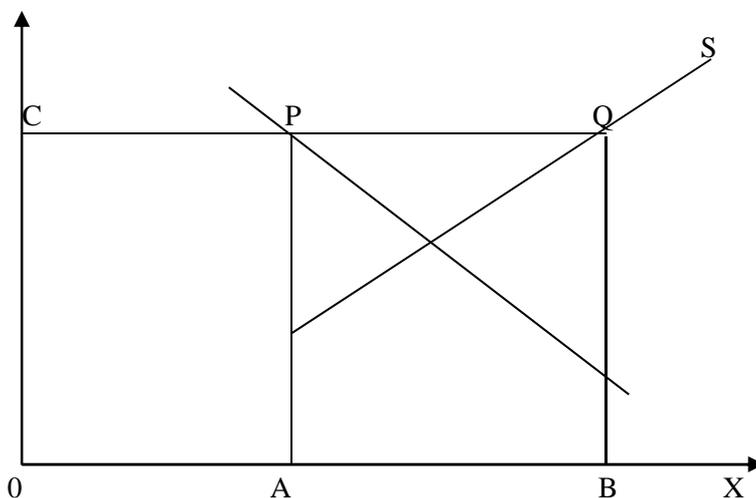

Careful examination of Keynes's definition and clarifications of involuntary unemployment enable us to conclude that Keynes changed Walras's assumptions. Namely, Keynes assumed that the total supply function of labour is weakly increasing function, and not strictly increasing (and decreasing) function as Walras assumed. This means that such supply functions might be characterized by a horizontal segment. And secondly, as a result of the first assumptions, in this case of a certain magnitude of wage, there might be a number of magnitudes of quantities of labour. Therefore, in the equilibrium state there might be involuntary unemployment if the equilibrium point is located on the horizontal segment that excluded its boundary points (vide infra). So, Keynes stated that involuntary unemployment is characterized by the rigid-wage phenomenon, and consequently, allows describing the supply curve of labour with a horizontal segment. Moreover, he also hinted to measure the magnitude of involuntary unemployment as a difference between the right boundary point of the segment and equilibrium point of employment. Thus, in the absence of rigid wages, there is also no involuntary unemployment. Hence, Keynes assumed that involuntary unemployment may or may not occur. Keynes's own words: 'Obviously, however, if the classical theory is only applicable to the case full employment, it is fallacious to apply it to the problems of involuntary unemployment - if there be such a thing (and who will deny it?)' (Keynes, 1936-1960, p. 6). Keynes also claimed that "involuntary unemployment," as well as "voluntary unemployment," is equilibrium phenomena (Keynes, 1936-1960, p. 28).

These assumptions, particularly (2), allowed post-Keynesian economists to define "involuntary unemployment" relatively clearly (Negishi, 1979, p. 27; Sachs & Larrain, p. 62).

On the other hand, Lange was one of the first economists to define involuntary unemployment graphically that is closely to its genuine meaning in economics literature. To gain understanding of Lange's version, here is a long quotation from *Prices Flexibility and Employment* (Lange, 1944, p. 6, note 4):

“Involuntary unemployment” in the Keynesian sense is not an excess supply of labor but an equilibrium position obtained by intersection of a demand and a supply curve, the supply curve of labor, however, being infinitely elastic over a wide range with respect to money wages, the point of intersection being to the left of the region where elasticity of supply of labor to money wages become finite. Thus “involuntary unemployment,” in the Keynesian sense, does not imply excess demand for cash balances, as well as for all other goods are supposed to be in equilibrium in the Keynesian theory. The difference is shown on the adjoining diagram (See Figure 2).

Figure 2. Lange’s Definition of Involuntary Unemployment

Source: Lange, (1944, p. 6).

D is the demand curve and S is the supply curve of the factor. In our treatment “underemployment” is the excess supply $AB (= PQ)$, while Keynes considers the line CQS as the supply curve, P an equilibrium point, and $PQ (= AB)$ involuntary unemployment. Change in price (OC) appears in the Keynesian theory as a shift of the horizontal part (CQ) of the supply curve. As is easily seen, our treatment is translatable into Keynesian terms

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

and vice versa. The choice is merely a matter of convenience. It seems that our method ties up more easily with general price theory.”

Lange correctly defined involuntary unemployment but, unfortunately, he identified it with total unemployment, which is only correct in one case (*vide infra*). Namely, by Lange’s definition “involuntary unemployment” only exists if the labor supply curve includes the horizontal segment (the part with rigid wages) (see Modigliani, 1944, p. 65) and the equilibrium point is located on this line, except at the borders. In other words, involuntary unemployment occurs if the employment equilibrium point is located to the left of the right border point of the horizontal segment and is determined as a difference between the latter and former equilibrium points. This means that “involuntary unemployment,” if it exists, *is an equilibrium phenomenon*. By this definition of involuntary unemployment, Lange made a *very important contribution*. At the same time, he did not connect his definition to the size of the available labour. Namely, he did not clarify if the right border point can be identified with the size of available labour force, or the latter is greater than the former, as might be understood from Lange’s figure. Thus, Lange did not define “voluntary” unemployment or discuss “full” employment. Therefore, he created a situation in which it seems that involuntary and voluntary unemployment cannot co-exist. Surely, this cannot be so.

Two Examples of Controversial Definition of Involuntary Unemployment

There are many controversial definitions of involuntary unemployment, but here we have chosen two examples because the major definitions are variations of these definitions.

Patinkin’s version of involuntary unemployment

Patinkin rejected Lange’s definition of Keynes’s involuntary unemployment claiming that: ‘... our interpretation does not tie the Keynesian theory of unemployment to any special form of the supply function for labor. In particular, it is independent of the all-too-frequent assumption that this theory presupposes a supply curve for labor as represented in figure XIV-1 (Patinkin, 1965, p. 342). The crucial characteristic of this curve is that it remains infinitely elastic at the prevailing-and presumed rigid-money wage rate ω_0 until the point N_0 . Accordingly, writers who make use of this curve identify the maximum amount of employment that workers

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

are to offer at the rate ω_0 with the level “full employment,” and define involuntary unemployment as the difference between this level and the one actually existing in the economy, say N_1 ’ (Patinkin, 1965, p. 341). In principle, this is the correct description of Lange’s definition of involuntary unemployment, but two observations should be made (*vide supra*). First, Lange did not consider “the maximum amount of employment” and “full employment”. Second, in Lange’s approach, involuntary unemployment is determined by the equilibrium point and not by “the one actually existing in the economy”, as Patinkin claimed. He continued: ‘If the curve did not have this shape, but instead always rose (no matter how slowly), and if at every wage rate workers were always at the uniquely corresponding point upon the curve, then, by definition, no involuntary unemployment could ever exist in the system: workers would always be receiving as much employment as they desired at the prevailing wage rate’ (ibid.). There are two important points: (1) (The) involuntary unemployment exists only if the labor supply curve includes a horizontal segment, which is correct. (2) Conversely, if the labor supply curve “always rose (no matter how slowly)”, then “workers would always be receiving as much employment as they desired at the prevailing wage rate”, which is incorrect. Patinkin rejected Lange’s “partial” definition of involuntary unemployment and tried to define it “generally” (see Boianovsky 2006).

Let to start with Patinkin’s definition of full employment: ‘It follows that a state of general equilibrium in the economy as a whole, or even a state of partial equilibrium in the labor market, by itself, is *ipso facto* of full employment. It also follows that the bench mark of full employment is not an absolute constant, but something which itself varies with every change in the real wage rate or in the subjective determinants of the labor supply curve’ (Patinkin, 1965, p. 315). Patinkin has defined, here, the full employment as an equilibrium employment which is incompatible neither with Keynes’s definition, which included voluntary unemployment into full employment, and not with a practical definition by which full employment means that the whole available labor has to be employed.

Patinkin’s definition of involuntary unemployment in its original form (Patinkin, 1965, pp.314-15; see also Leontief, 1947) is:

‘The norm of reference to be used in defining involuntary unemployment is the supply curve of labor; . . . Hence as long as workers are “on their supply curve” – that is, as long as they succeed in selling all the labor they want to at the prevailing real wage rate – a state of full employment

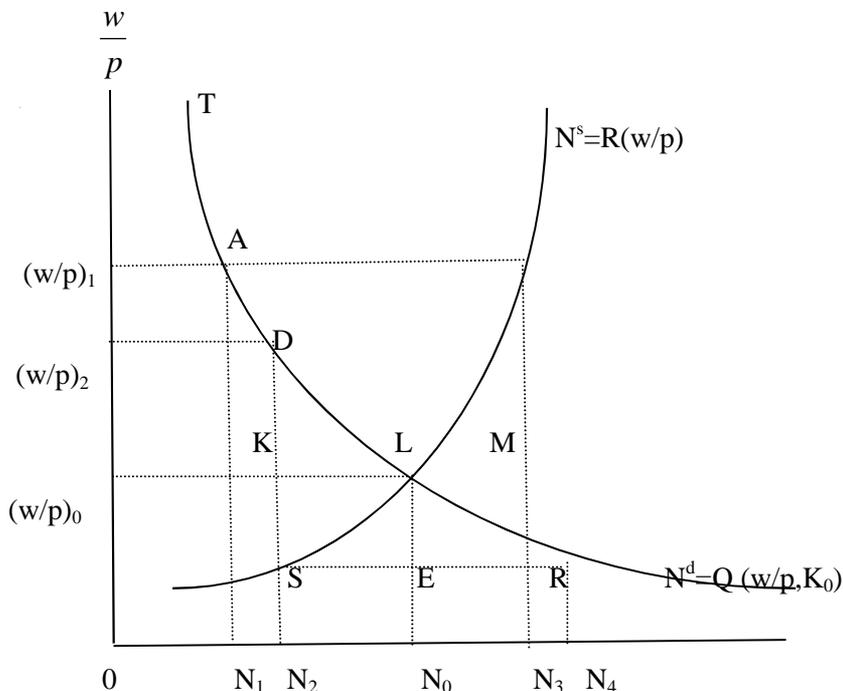

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

will be said to exist in the economy. It follows that a state of general equilibrium in the economy as a whole, or even a state of partial equilibrium in the labor market by itself, is *ipso facto* a state of full employment. It also follows that the bench mark of full employment is not an absolute constant, but something which itself varies with every change in the real wage rate or in the subjective or objective determinants of the supply curve. ... Conversely, if workers are not on this curve, they are acting involuntarily. Thus, if they are at the point *A* in Figure XIII-1 (see Figure 3) ..., involuntary employment to the extent $N_3 - N_1$ exists. On the other hand, if they are at the point *E*, there exists involuntary unemployment to the extent $N_0 - N_1$.²

So, Patinkin gave two different definitions of involuntary unemployment. First definition, is the disequilibrium position, which contradicts Keynes's important statement that involuntary unemployment is an equilibrium phenomenon; and, moreover, he ignore Lange's statement that "Underemployment, having been defined by us as excess supply of a factor of production, implies thus existence of excess demand somewhere else in the economy. This treatment of underemployment differs from the "involuntary unemployment" as defined by Lord Keynes' (Lange, 1944, p. 6, note 4); and by this Patinkin replaced Lange's "underemployment" by Keynes's "involuntary underemployment"; yet, according to Walras's approach it is as "forced unemployment" at the *minimum* wage (point *A*) (*vide supra*). Second definition, is based on two different wages, equilibrium and disequilibrium, hence it is nonsense (absurdity) (see also Patinkin, 1949, p. 369).

² In the origin (N_2), but in the paper "Unemployment and Keynesian Supply Functions" Patinkin asserted 'involuntary unemployment (to the extent $N_1 - N_2$); which are parallel with $N_0 - N_2 - E. D.$), be said to exist in the system' (Patinkin, 1949, 1965, p. 369).

Figure 3. Patinkin's definition of Involuntary Unemployment

Source: (Patinkin, 1965, p. 316).

Patinkin also considered two additional concepts of involuntary underemployment in the spirit of interpretation of Keynes's macroeconomic theory. In this case only one side of economic phenomenon either aggregate demand or aggregate supply is dominant in the definition of involuntary underemployment. Patinkin asserted: 'In other words, only the desires of demanders influence the determination of national income, while the desires of suppliers are completely ignored. We would then have as a measure of the extent of involuntary underemployment (U) in the system

$$U = \eta - Y_0$$

That is, involuntary underemployment is measured by the difference between the level of national income in the norm reference, η , and the level actually prevailing, Y_0 ' (Patinkin, 1949, p. 371). On the other hand, he continued: "In brief, the level of national income desired by spenders (Y_7) is

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

greater than that desired by suppliers. If the level of national income is actually Y_7 , then a measure of the extent to which suppliers are over-employed is the negative quantity

$$U = \eta - Y_7$$

That is, involuntary over-employment is measured by the difference between the level of national income in the norm of reference, and the level actually prevailing' (Patinkin, 1949, p. 374; see also Trevithick, 1992, pp. 108-9). It must be stressed that what Patinkin defined as involuntary over-employment is equivalent with the *forced unsatisfied demand for factor (labour)* according to Walras's approach (vide supra).

To sum up, to define involuntary unemployment correctly requires the correct definition of full employment³. What Patinkin calls "involuntary unemployment" is underemployment according to Lange's determination and "forced unemployment according to Walras's approach; and what Patinkin calls "involuntary over-employment" is "forced unsatisfied demand of factor (labour)" at the *maximum* wage according to Walras's approach.

Shapiro and Stiglitz's version of involuntary unemployment

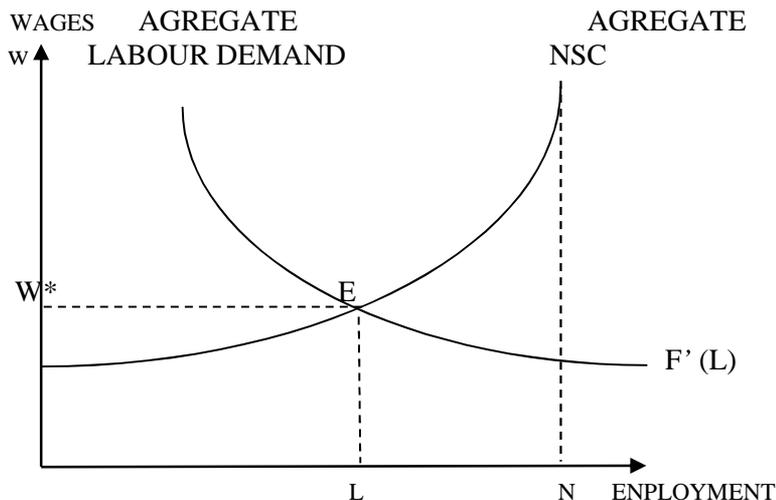

Shapiro and Stiglitz claimed (see Figure 4) that:

'The equilibrium is depicted in figure 2 (see Figure 4 – E.D.). It is important to understand the forces that cause E to be an equilibrium. From the firm's point of view, there is no point in raising wages, since workers are providing effort and the firm can get all the labor it wants at w^* . Lowering wages, on the other hand, would induce shirking and be a losing idea.

³ It is necessary to stress that Klein was the first, in our opinion, who defined "unemployment" similar to Patinkin (see Klein, 1952, pp. 80-87). We decided to use Patinkin's version because it is much more comprehensive and used in majority of the modern literature (or textbooks) for Macroeconomics (for example see Chick, 1984; Taylor, 1987; Sachs & Larrain, 1993).

From the worker's point of view, *unemployment is involuntary*: those without jobs would be happy to work at w^* or lower but cannot make a credible promise not to shirk at such wages' (Shapiro and Stiglitz, 1991, p. 131).

Figure 4. Equilibrium Employment

Source: Shapiro & Stiglitz, 1991, p. 132.

The first statement is correct, in our view, but not the second one. Thus, if the supply curves of labour is determined on the basis of labour supply of individuals, then 'those without jobs' are in that state because of the labor conditions they offer, or out of their own choice, and due to the market forces. But when they discover they are out of work, they might decide to change the labor conditions they offer. However, in such cases, there would be a new equilibrium process, and, hence, a new equilibrium point, would be established. Thus, it is incorrect to call it *involuntary unemployment*; it is the opposite, it is *voluntary* (vide infra).

The Comprehensive Approach to Unemployment

Based on the above, we can formulate the comprehensive theory of unemployment. According to Walras's approach, kinds of unemployment

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

depend on the type of economy under discussion, namely, is the economy characterized by free competition, where the market forces govern the activities of economy; or are there external forces (government, monopoly and so on) which intervene in the activities of economy. Walras shows that in the previous case, in the framework of his assumptions, there is voluntary unemployment and in the latter case there is forced unemployment. Keynes, unfortunately, combined these two types of unemployment and called it “voluntary” and introduced an additional type of unemployment – involuntary, which is also derived from the free competition such as voluntary unemployment, but with different assumption. This paper discusses only the approach of pure theory, so the term “voluntary” is used in Walras’s sense.

Several fundamental statements provide the general framework for the definition of unemployment. First, it is an equilibrium phenomenon, i.e., unemployment requires a definition of the equilibrium situation. The latter is established when effective supply of factor (labour), which is obtained by the supply curve of factor (labour), equals the labour demand, which is obtained either from the labour demand curve (Keynes-Lange) or the equation system, based on the demand for consumption goods (Walras). Second, if the quantity of the equilibrium point is less than the available quantity of the factor, then there is either involuntary unemployment (Keynes-Lange) or voluntary unemployment (Walras). But if the equilibrium point is equal to the boundary point of the supply curve, which is identified with available quantity, then there is neither involuntary unemployment nor voluntary unemployment, but there is full employment.

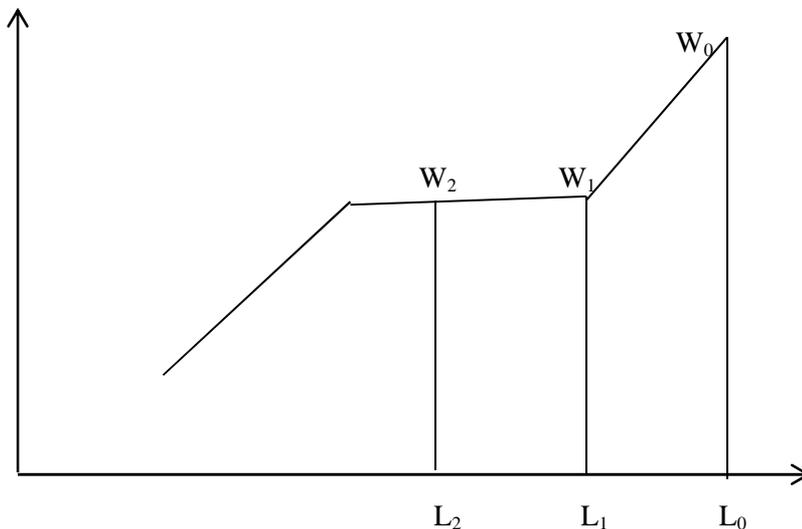

In Walras’s version, unemployment (voluntary) is obtained when the supply curve is strictly increasing and its right boundary point is identified with the available quantity of a factor. This means that in Walras’s approach, for every wage, there is only one effective supply; hence equilibrium point is established if it exists when effective demand is met by effective supply.

Lange’s version of Keynes’s involuntary unemployment is obtained when the factor supply curve has a horizontal segment. Namely, the supply curve is weakly increasing curve. In other words, in this case, for one wage of a labour, there are several quantities of supply, but there might be one equilibrium point, therefore, might be involuntarily unemployment and its

magnitude is a difference between the right boundary point and equilibrium point. Also, in this horizontal segment, the elasticity remains infinite⁴.

Thus, as concluded above, Walras defined voluntary unemployment and linked it to the full employment, but he did not and could not consider involuntary unemployment. On the other hand, Lange defined Keynes's involuntary unemployment, but he did not connect it with full employment and voluntary unemployment. Combining these two definitions of unemployment provides the comprehensive approach to unemployment. Therefore, for this purpose, assuming that the supply curve should include non-increasing segment and the right boundary point of curve is identified with the factor's available quantity (see Figure 5).

Figure 5. The Comprehensive Approach to Unemployment

Source: own work.

⁴ Hence we cannot agree with Darity and Young, who recently suggested that 'His definition would have been the following: involuntary unemployment exists if the elasticity of employment (and output) is greater than zero with respect to an increase in aggregate demand' (Darity & Young, 1997, p. 26) because if elasticity is greater than zero, then there might be only voluntary unemployment.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

If the equilibrium is at point W_0 (available quantity), then there is neither involuntary unemployment nor involuntary unemployment, that is, there is the full employment. If the equilibrium point is at W_1 , then there is only voluntary unemployment, which is determined as the difference between L_0 and L_1 . If the equilibrium point is at W_2 , then both voluntary unemployment and involuntary unemployment exist. The former is determined, as in the previous case, but the involuntary unemployment is the difference between L_1 and L_2 . The total unemployment is the summation of these two kinds of unemployment, i.e., it is determined as $(L_0 - L_1) + (L_1 - L_2) = (L_0 - L_2)$. Finally, let us consider two extreme forms of the supply curve: (1) If the supply curve is only a horizontal line, then there is either full employment if the equilibrium point is at the right boundary, or there is only involuntary unemployment, which is obtained as a difference between the boundary (available quantity) and equilibrium points (equilibrium employment). (2) If the supply curve is only a vertical line, there is full employment in all cases.

To sum up, in the framework of free competition, the kind of unemployment, if it exists, depends on the character of assumptions, i.e., on the form of the supply curve of labour. Generally, there are four possible cases: full employment, voluntary unemployment only, involuntary unemployment only, and, finally, both voluntary and involuntary unemployment.

Unemployment and Textbook of Macroeconomics

The problems of unemployment may be cured by a new generation of economists – if they understand these problems. Unfortunately, Macroeconomic textbooks do not facilitate this, because the definition of Unemployment is so confusing and unclear that it is impossible to study anything. To illustrate our above statement, we start with a discussion of the definition of voluntary and involuntary unemployment in macroeconomic textbooks. It is amazingly difficult to find textbooks where voluntary and involuntary unemployment are considered, and if they are considered then it is in a very confusing form (Lipsey *et al.* 1990). Mankiw and Krugman (2009), two eminent new-Keynesians, who are leading supporters and propagandists of the “Keynesian Revolution”, never mention term “involuntary unemployment” in their textbooks. But, it is Keynes’s truly unique contribution!

Sachs and Larrain (1993), correctly define involuntary unemployment in principle: ‘The notion of involuntary unemployment is that some people

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

who are willing to work for the wage received by other workers of comparable ability cannot do so' (Sachs & Larrain, 1993, p.62). But, following this, it is not clear how its magnitude is calculated. If we take into account the definition that the unemployment rate 'measures the number of people who are without a job and are actively, searching for a job, as a proportion of the total labor force' (Sachs & Larrain, 1993, p. 5), this means that to calculate any unemployment, two sets of data are required: the total labor force and the amount of employed people. They forgot about this statement when the voluntary and involuntary unemployment is discussed. Moreover, they asserted 'There is, in fact no standard accepted procedure to estimate the natural rate of unemployment, and leads to disagreements about methods and magnitudes' (Sachs & Larrain, 1993, p. 506).

This is not exact; because the natural rate of unemployment is calculated according to the equilibrium state: 'the "natural" rate of unemployment as the rate which corresponds to macroeconomic equilibrium, in which expected inflation is equal to its actual level' (Sachs & Larrain, 1993, p. 496). The problem is how to achieve macroeconomic equilibrium.

On the other hand, Krugman and Wells define the natural unemployment rate as '*The natural rate of unemployment* is the normal unemployment rate around which the actual unemployment rate fluctuates. It is the rate of unemployment that arises from the effects of frictional plus structural unemployment' (Krugman & Wells, 2009, p. 210). When "*Frictional unemployment* is unemployment due to the time workers spend in job search" (Krugman & Wells, 2009, p. 207) and 'Structural unemployment is unemployment that results when there are more people seeking jobs in a labor market than there are jobs available at the current wage rate' (Krugman & Wells, 2009, p. 208), where did the total labor force disappear? What about Macroeconomics equilibrium?

Conclusions

In this paper it was shown that Keynes's involuntary unemployment derived from Walras's voluntary unemployment by means of changing of the characteristic of the aggregate supply curve (function) of labour.

It was shown that the kind of unemployment depends on the character of the original aggregate supply curve of labour. On the one hand, when the original aggregate supply function is a strongly increasing function, as in Walras's approach, there might be only voluntary unemployment, and its magnitude is the difference between the available quantity of labour and the

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

equilibrium point. So, in such a case, an individual is unemployed according to his own wishes, because an equilibrium wage defined by free competition is less than a wage which he requires. But, at the same time it is incorrect to confuse Walras's voluntary unemployment with leisure. Moreover, unfortunately, some modern economists mistook Walras's voluntary unemployment with "involuntary unemployment".

According to Walras's approach also might be considered "forced unemployment" which is the result of an intervention of external forces (government, monopoly, trade unions, and so on) into the market, and therefore, it is a disequilibrium phenomenon. Unfortunately, Keynes combined Walras's two types of unemployment, voluntary and forced, and called them "voluntary" unemployment. On the other hand, some economists interpreted Walras's forced unemployment as "involuntary unemployment".

On the other hand, if the supply curve of labour is a weakly increasing, which means that the supply function may have a horizontal segment then there might be involuntary unemployment if the equilibrium point locates between boundary points of the horizontal segment, and the magnitude of involuntary unemployment is the difference between the right boundary point of the horizontal segment and an equilibrium point. So, in such a case, an individual is involuntarily unemployed against to his own wishes, because an equilibrium wage defined by free competition is equal to a wage which he requires.

The comprehensive approach of employment was presented in the end of the paper. It was shown that the existence of involuntary unemployment depends on the character of the original aggregate supply curve of labour, and is connected with the existence of voluntary unemployment and full employment. Involuntary unemployment might not exist if there is either full employment or only voluntary unemployment, or it might exist alone or together with voluntary unemployment. Finally, in reality there are many types of labour, hence a suggested comprehensive approach of employment might be a useful tool for policy making and planning of economics.

On the Evolution of Corruption Patterns in the Post-Communist Countries

JEL Classification: *D73; P21; P37*

Keywords: *corruption; Markov transition probability matrix; post-communist countries*

Abstract: In this paper, we study the evolution of corruption patterns in 27 post-communist countries during the period 1996-2012 using the Control of Corruption Index and the corruption category Markov transition probability matrix. This method allows us to generate the long-run distribution of corruption among the post-communist countries. Our empirical findings suggest that corruption in the post-communist countries is a very persistent phenomenon that does not change much over time. Several theoretical explanations for such a result are provided.

Introduction

Corruption is a global phenomenon and no country in the world is completely free from corruption. In one characteristic or another, to a smaller or greater extent, it is present in all countries, at all stages of development and under all types of economic policies pursued by the state itself. Developed or developing, large or small, market-oriented or other, governments in all countries have fallen because of accusations of corruption. Top politicians not excluding heads of states have lost their offices, power, and sometimes even their lives in coups and revolutions caused by such allegations.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

Corruption seems to manifest itself in all societies that pass a certain degree of complexity. It dates back to the very first instances of organized human life and has been present ever since (Klitgaard, 1988). One of the oldest examples of corruption is more than 2,300 years old. Chānakya, prime minister to the first Maurya Emperor Chandragupta (c. 340-293 BC), and the architect of his rise to power, analyzed the phenomenon of corruption in his work *Arthaśāstra* (Boesche, 2003; Bardhan, 1997). In China, the penal code of the Qin Dynasty (211-206 BC) included corruption and put heavy penalties on people accused of it. Dante Alighieri placed bribers in the deepest part of hell. Shakespeare gave corruption a prominent role in some of his plays. The American Constitution explicitly mentions bribery and treason as the two crimes that could justify the impeachment of a U.S. president.

The problem of corruption has always attracted a great deal of attention among the social scientists. However, due to the fact that limited empirical work exists on corruption prior to 1995 makes learning from history difficult. For example Bardhan (1997:1329) notes that: “Although the requisite time-series evidence in terms of hard data is absent, circumstantial evidence suggests that over the last 100 years or so corruption has generally declined with economic growth in most rich countries”. One possibility is that corrupt deal exposure is much more probable in more economically developed countries. In addition to its clear impact on democracy economic development improves the spread of education, literacy, and depersonalizes economical relationships — each of these ought to increase the likelihood that an misuse of public power will be detected and tackled (Treisman, 2000). Thus, policies that boost growth, if successfully implemented, are likely to reduce corruption in the long run. Paldam (2002, p. 20) suggests that with “the complex transition from a poor traditional country to a wealthy liberal democracy also comes a dramatic reduction in the level of corruption. The corruption transition is not placed at a precise location along the transition path, but follows an underlying transition-trend toward less corruption.”

In the context of the post-communist countries of Central and Eastern Europe, the Baltics, the Commonwealth of Independent States as well as Mongolia corruption has been recognized as an integral part of the communist system (Sandholtz, Taagepera, 2005). However, despite 25 years of transition and continuous economic development many people perceive that corruption, instead of falling, has risen in those countries after the fall of communism. The simultaneous processes of developing a market economy, designing new political and social institutions, and the redistribution

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

of state-owned assets in the post-communist countries have created fertile ground for corruption to flourish. After the fall of communism non-transparent privatization, stalled liberalization of prices and commerce, and underdeveloped legal and regulatory systems worsened the situation even further and have all come in for their share of sometimes well-deserved criticism. Not surprisingly, corruption in some of the countries that emerged from the former Soviet Union is perceived to be the heaviest in the world, imposing a heavy burden on their economies and slowing down their economic development.

The main aim of this paper is to study the evolution of corruption patterns in the 27 post-transition states during the period 1996-2012. The research methodology employed in this paper is as follows. First, we provide some stylized facts on corruption in the post-communist countries against a backdrop of various regions of the world using the Control of Corruption Index developed by the World Bank. Then, a corruption category Markov transition probability matrix is used to predict the long run distribution of corruption among the post-communist countries. Our empirical findings suggest that corruption in those countries is a very persistent phenomenon that does not seem to change much over time.

The structure of this paper is as follows. In Section 2 we briefly survey the literature on various types of corruption with the special focus on the post-communist countries. In Section 3 we discuss advantages and disadvantages of various measures of corruption. In Section 4 we study corruption patterns across the world and compare the whole group of the post-communist countries against other groups of countries and describe the corruption levels and trend in the particular post-communist countries. In Section 5 we investigate the stability of corruption patterns in the post-communist countries using the Markov transition probability matrix. Section 6 summarizes and concludes with policy recommendations and directions for further studies.

Overview of corruption in post-communist countries

Corruption is a complex phenomenon with multiple causes and effects as it takes on various forms and functions in different contexts. Accordingly, the problem of corruption has been seen either as a structural problem in political sciences, as an incentive problem in economics or as a cultural and individual moral problem in other social sciences. In any case, corruption is a multifaceted problem even in its concrete appearance and no single model

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

approach will be able to describe the whole picture in an adequate way. Consequently, there exists a whole multitude of definitions and each definition seems to be falling short in some aspect.

One of the most commonly used general definitions of corruption was introduced by the World Bank (2000) which defined it broadly as “the abuse of public office for private gain”. However, several subsequent World Bank studies attempted to go beyond this broad definition. These studies identified two forms of corruption and tried to capture qualitatively their extent (Hellman et. al 2000, 2003, and 2004). Their authors employed survey data from the 1999, 2002, and 2005 Business Environment and Enterprise Performance Survey (BEEPS) collected from firm managers and owners in Central European and the Commonwealth of Independent States countries. The data was used to quantify two kinds of corrupt behavior.

The first type is called State Capture and refers to the capacity of firms to shape and affect the formation of basic rules of the game (i.e. laws, regulation, and decrees) through private payments to politicians. This type of corruption is also commonly referred to as “political” or “higher level” corruption. The second type is called Administrative Corruption and refers to so called “petty” or “low level” forms of bribery in connection to implementation of existing laws and regulations by the bureaucracy.

Undoubtedly, many other definitions and classifications of corruption can be found in the literature. In fact, most of the work in sciences other than economics is dedicated to provide a more complex picture of corruption. Anthropological studies go even as far as to say that no possible definition of corruption can exist since all human actions are incomparable to one another. In contrast, most studies in economics take a parsimonious view focusing only on ‘as if’ market outcomes of corruption. Therefore, for the purposes of this study we decided to use the following definition: corruption is an act in which the power of public office is used for personal gain in a manner that contravenes the rules of the game (Jain, 2001).

In the context of the post-communist countries corruption was often recognized as a heritage of the communist system. While the collapse of communist regimes in many countries across the region altered the structure of opportunities and incentives for corruption, it did not eliminate them. In the face of the fall of the command economic system, the structure of informal personal ties between people did not cease to exist, nor did the distrustful attitude towards the state. With a change in the post-Soviet political regime after the subsequent progress of economic and social transformation initiated changes in the background and environment of corruption.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

Furthermore, privatization after the collapse of communism created new incentives and opportunities for corruption (Kaufmann and Siegelbaum, 1997; Stiglitz, 1999; Hoff, Stiglitz, 2004).

The possibilities and the scope for corruption in the post-communist countries – given the mixture of massive privatization, weak states, and underdeveloped civil societies – have been considerable. The simultaneous developments that occurred along with economic and legal transformation sometimes led to an increase in large-scale corruption. This indistinct flux and institutional vacuum produced many economic rents which were later captured by the corrupt. The totalitarian power of the state has been relaxed and the formal and informal institutions that controlled and organized corruption in the past were eliminated or were in a decline (World Bank, 2006). This allowed corruption to flourish, since most of the countries had no civil society and therefore the accountability of the reformers (some of which were communist politicians) was non – existent. Moreover, it was argued, that corrupt masses democratically generated new corrupt elites even when the former communist elites were forced out (Sandholtz, Taagepera, 2005).

Therefore, after the fall of communism many people perceived that corruption instead of falling had in fact risen in the post-communist countries. A massive process of property redistribution resulted in a restoration of the informal personal ties, presently on the borders between the formerly omnipresent state and the newly emerged private sector. As the economic process was taking place, the existence of corrupt practices was shifting from one sector of economic activity to another. Corruption shifted chiefly from the sector of general services and sales of goods to the region of state and administrative services.

Åslund (2002) provided an excellent account of the process of rent grabbing. According to him these rents were used later to corrupt public officials and perpetuate the rents even further. This was easy, because the network of interpersonal connections between people of various public occupations had been already set up and deeply entrenched in the economy. As the captured rents were perpetuating and increasing, they soon brought about more money to be seized by the means of directly influencing the creation of law and regulation. Before long, the captured state was born.

The result of the strategy of stalled partial reform was the rise of the captured states, dominated by corruption. It is difficult to describe the model of such a country, as it is a rather indistinct mixture of laissez faire state with heavy state intervention, when it comes to the economy. The general

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

vision that was shared by the “founding fathers” of such states was “maximum freedom for us, maximum regulation and intervention for others”. Economic growth did not arise as an objective of such elites, as they were mainly concerned with capturing the wealth that had already been formed by the means of market distortions, caused by overregulation and certainly not in the formation of the new. Therefore, the larger the initial distortions, mainly caused by collapsing central planning and underdevelopment, the larger were the rents.

The frequently quoted example of the captured state is Russian Federation. Interestingly, the greatest fortunes in Russia were made not through privatization of state owned companies, but through privatization of the credit given out by the Central Bank of Russia (Dąbrowski *et al.*, 2001), through arbitraging the differences between controlled prices for raw materials within Russia and free market prices abroad (Åslund, 1999), and through favoritism in natural resource based industries. “It was the Russian treasury, which was directly asset stripped, not the firms”, and the riches made during this period have maintained the political power of the oligarchs (Dąbrowski *et al.*, 2001). The results analogous to the Russian experience can be observed elsewhere, and in many countries the situation is even worse.

While Estonia and Slovenia were initially relatively free from the state capture, Ukraine, Bulgaria, Moldova, and many countries of Caucasus and Central Asia could be used as perfect examples of such captured states. Because only a select few had the access to the top officials being able to stall reforms, just these few gained on the process, creating immense wealth, at the cost of all of the public. Despite the common belief that the liberalization was the main source driving corruption, in reality, the relationship was opposite. Not privatization or stabilization stopped the post-communist economies in their tracks, but the outright extortion of rents and embezzlement of state assets. The money extracted, enabled to stop the necessary reforms, hence perpetuating corruption due to market distortions.

Therefore, in the subsequent sections we study the evolution of corruption patterns in the post-communist countries against the other regions of the world and then compare the levels of corruption among particular post-communist countries. However, prior to investigating the corruption patterns we discuss advantages and disadvantages of various corruption measures.

Measuring corruption

Despite the fact that a large number of press articles documenting individual cases of corruption in particular countries have been published, it is still difficult to estimate precisely the extent of corruption and to make cross country comparisons. No available quantitative information is based upon direct observation, with the exception of case studies that are extremely scarce and therefore not commonly used. The main problem in research on corruption has been the lack of systematic and internationally comparable statistical data. In a perfect world, the data used in empirical studies should be based on objective, direct, and firsthand observations of corrupt transactions made by unbiased observers who are experts on the rules and routines in the scrutinized sector.

However, the aforementioned conditions are rarely met in reality as corruption is usually deeply concealed. None of the parties of the corrupt deal has incentives to inform anyone else about it since corruption is illegal. Moreover, in contrast to other crimes, corruption has typically no individual victim who would be motivated to report the crime. Furthermore, corruption usually takes the form of complex transactions taking place in large hierarchies to which outsiders have no access. It usually involves informational asymmetries and therefore its observation is very indirect. As a result, corruption is hard to measure and empirical studies on this issue are in a short supply.

Some researchers have tried to estimate corruption indirectly with disputable success. In their studies, corruption was calculated from micro level data, like data on infrastructure projects, the use of cement, or data drawn from firm-level surveys. Even if argued to be successful, these accounts do not enable a comparative analysis since they concern two countries at most. Examples of such studies include Wade (1982) for India, Murray-Rust and van der Valde (1994) for Pakistan, Manzetti, L. and C. Blake (1996) for Latin America, Svensson (2003) for Uganda, Kuncoro (2004), and Henderson and Kuncoro (2004) for Indonesia, and Golden and Picci (2005) for Italy.

Asiedu and Freeman (2009) discussed and classified various measures of corruption used in previous studies into three categories: internal, external, and hybrid. Internal measures include those based on the perceptions of firms that operate within a single country. The external measures are based on the assessment of risk analysts who typically reside outside a country. Finally, the hybrid measures combine corruption data from different

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

sources into a single composite index. Each of those measures has its own advantages and disadvantages.

The typical procedure in constructing the internal measures is to survey firms in a particular country about their perceptions and experiences of corrupt practices. The main advantage of internal measures is that they reflect firms' perception of investment risks that affect firms' operational and investment decisions. At the same time, internal measures have several limitations. Firms that provide the corruption ratings operate in different countries face different economic and political environments and the collected data may not be easily comparable across countries. Moreover, the data can be affected by individual characteristics of firms, such as their age, size or industries in which they operate.

The external measures are compiled by commercial risk-rating agencies. The main advantage of those measures is that countries are rated by the same set of entities which makes the data more consistent and internationally comparable. External measures, however, suffer also from several disadvantages. The data coverage is usually limited and the country evaluations are usually not based on personal experience, but rather inferred from media reports. As a result, the levels of corruption reported by the consultants who compile those measures may not accurately reflect the actual levels of corruption.

The hybrid measures combine corruption data from different sources into a single composite index which allows mitigate the problems associated with the internal and external measures of corruption. In order to address those problems, researchers from the non-governmental organization Transparency International (TI) and the World Bank aggregated, using slightly different methodologies, various data on corruption gathered from a wide range of sources to create the so-called corruption perception indices. These two hybrid measures are the most widely used measures of corruption. Due to similarities in their construction these two indexes are correlated with each other. These indices allocate numbers for the level of corruption to almost every country in the world of some economic significance. Although some countries change the position from an index to an index and have different rankings in the TI and WB datasets, there is an overall constancy to the rankings. Therefore, most studies use one or the other of these two indices.

Perhaps the most popular hybrid index is the annual TI Corruption Perception Index (CPI) which is a compilation of corruption surveys and assessments that are averaged each three years around a given year and com-

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

puted since 1995. Constructed as a poll-of-polls index, the CPI is designed to capture the perception of well-informed people on corruption which are scored on a range of 0 (high) - 10 (low). The index aggregates the perceptions of respondents with regard to the extent of corruption – defined as the abuse of public power for private benefit. Here the extent of corruption reflects the frequency of corrupt payments and the resulting obstacles imposed on businesses.

Although TI's CPI index has been the most popular hybrid index, it has not been free from criticism. For the 1995 and the historical data (1980-1985, 1988-1992), this index was constructed by taking simple averages after transforming the various different scales – drawn from different data sources – into 0-10 scale. The normal standardization technique was introduced in 1996 but stopped in 2001. The matching percentile technique and the transformation were introduced in 2002 and applied since then. Due to these changes, the CPI cannot be regarded as a consistent time series.

The World Bank has made use of the underlying sources that make up the TI index and has produced its own Control of Corruption Index (CCI) using an arguably better aggregation method and including more countries and sources. Kaufmann et al. (2006), authors of this index, provide a very extensive rebuttal (with empirical proofs) of most of the arguments raised by its critics. Arndt and Oman (2006) in their extensive survey of the many different indicators referred to the World Bank Control of Corruption Index as "probably the most carefully constructed governance indicator".

Therefore, our measure of corruption used in this study is the Control of Corruption Index compiled by Kaufmann et al. (2005). Since what actually matters in our empirical investigation are perceptions of outsiders, the World Bank data seems to be especially well suited. The World Bank index covers about 200 countries and is computed on the basis of individual variables relating to perception of corruption, drawn from about 40 data sources produced by more than 30 different organizations. In our study we focus on the sample of 27 post-communist countries for which data are available starting from 1996 until 2012.

Despite the fact that the CCI is "probably the most carefully constructed governance indicator", it has several weaknesses. In particular, it shares the common weakness of drawing on public opinion pools. Therefore, one must be aware that this index measures perceptions rather than being an objective measure of corruption. It could be the case that if a particular country's score differs from a survey to a survey, it occurs mostly so because of a shift in perceptions. For instance, media coverage of high-level

corruption prosecutions may increase public's perception of corruption, while the "real" level of corruption may actually decrease. Another important drawback of this index is that since the data are a composite measure, they do not differentiate among various forms of corruption, such as high-level versus low-level corruption or well organized versus poorly organized corruption or corruption with theft versus the one without, initiated by private party, extorted by the official and so on.

The most effective response to the arguments surveyed above is to be aware of the inherent limitations of any given statistical instrument. Despite all of the listed limitations and critiques, the hybrid indices provide a lot of useful information. They have laid solid foundations for anticorruption efforts of such prominent organizations as the World Bank, OECD, UNDP, IMF, and the EBRD.

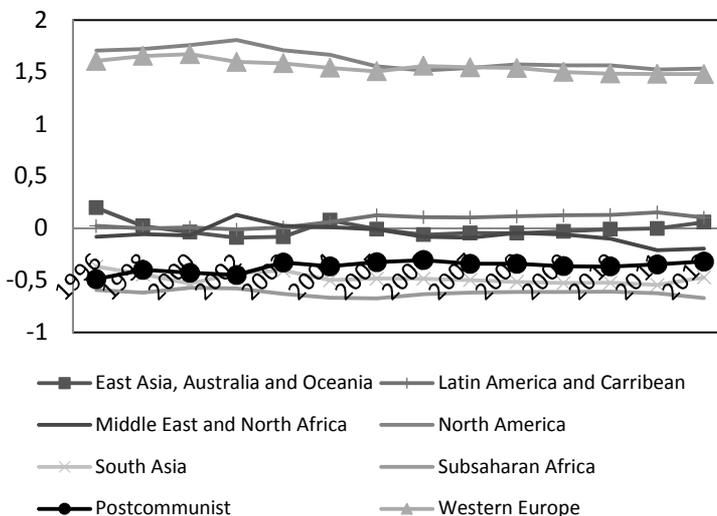

Corruption levels and trends in the post-communist countries

In this section we first study the general corruption patterns across the world and compare the whole group of the post-communist countries with other groups of countries and then we describe the corruption levels and trends in the particular post-communist countries. In Figure 1 we show the distribution of corruption across various regions of the world. The assignment of countries into each category follows the World Bank classification. The groups have been enumerated in the annex at the end of the paper.

It can be seen from Figure 1 that the post-communist countries constitute one of the clusters of countries in the world, which show the highest levels of corruption. Not surprisingly, the level of corruption in post-communist states makes this region on par with the most corrupt countries in the world. In particular, post-communist corruption goes hand in hand with corruption in Sub-Saharan Africa and South Asia, and is visibly higher than corruption in the Middle East and North African (MENA) countries.

Until the early 2000s the post-communist countries as a group were the most corrupt countries in the world. Although there seems to be a positive trend, it is very weak and the post-communist countries still exhibit one of the worst instances of corruption. Thus, it could be concluded that despite the advances in reforms, the level of corruption in the post-communist countries remains high and does not seem to diminish significantly over time.

Figure. 1 Distribution of corruption among various country groups

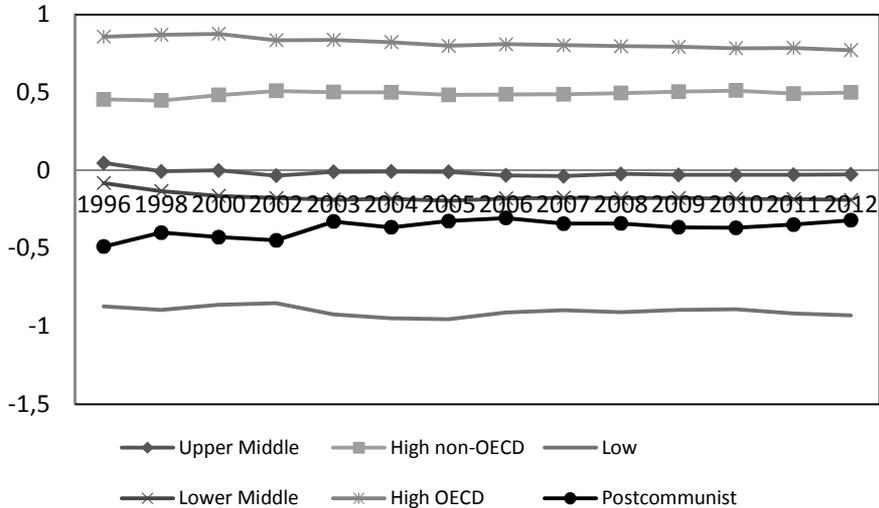

Source: own elaboration based on World Bank CCI data.

Moreover, a further point could be made that the post-communist countries exhibit a higher level of corruption than their level of development would suggest. This can be seen in Figure 2, which shows the income distribution of corruption.

In terms of material wealth, majority of the post-communist countries fare between lower middle income and upper middle-income groups. Some of these countries even managed to reach the highest-income group, as seen in the appendix. However, it can be seen from Figure 2 that the group of communist countries displays corruption behavior of the in between the two low-income and lower middle-income countries.

Figure. 2 Income groups distribution of corruption

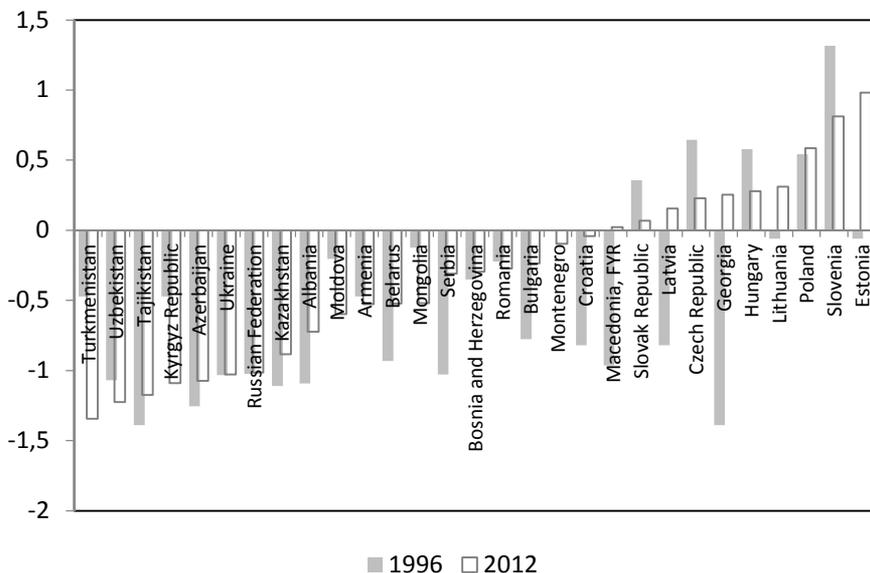

Source: own elaboration based on World Bank CCI data

In Figure 3, we compare the levels of corruption in particular post-communist countries in the first year of our sample – 1996 and in the last year – 2012.

It can be noted from Figure 3 that a great deal of heterogeneity exists among the post-communist countries. The highest levels of corruption are reported in the successor states of the former Soviet Union with the exception of three Baltic countries that from the beginning opted for integration with the West, radically reformed their economies, and joined the European Union in 2004. Among those states, Estonia is the absolute leader in which has the lowest and even further decreasing level of corruption among all the post-communist countries. Among the former Soviet Union countries in which the levels of corruption are the highest are the Central Asian and the Caucasus states such as Turkmenistan, Uzbekistan, Tajikistan, Kyrgyz Republic, and Azerbaijan. These countries are followed by the East European countries such as Ukraine and the Russian Federation. Among the least corrupted states, in addition to the Baltics, are the Central European countries such as Slovenia, Poland, and Hungary.

Figure 3. Corruption levels in particular post-communist countries

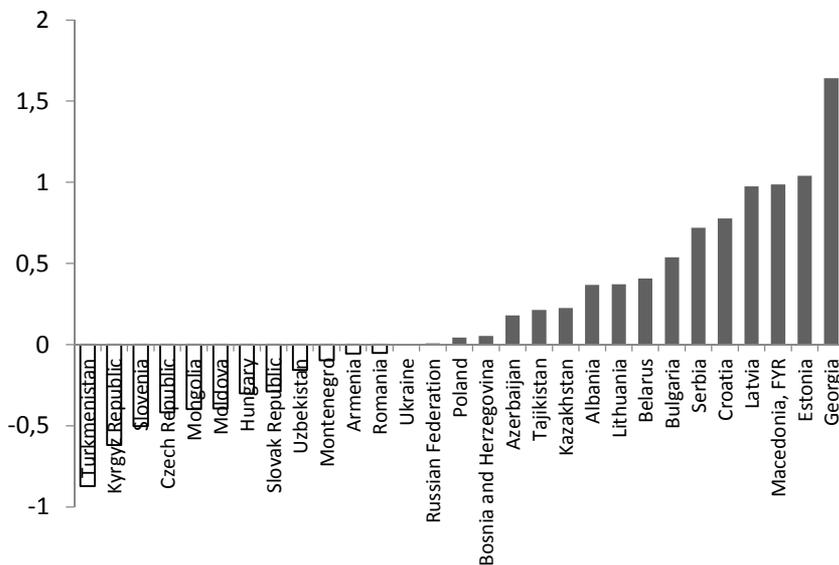

Source: own elaboration based on World Bank CCI data.

In Figure 4, we show the changes in the level of corruption for particular post-communist countries in the period 1996 – 2012. This allows us to identify countries in the region, which experienced the biggest decreases, and increases in the level of corruption.

It can be noted that the level of corruption in the most corrupt countries in Central Asia such as Turkmenistan or Kyrgyz Republic has increased over time while the level of corruption in the majority of the least corrupt countries, such as the Baltic countries, decreased. Interestingly, in many Central European countries, such as Slovenia, the Czech Republic, Hungary, and the Slovak Republic, which initially started with low levels of corruption, corruption increased over time. The only exception in this group was Poland where the level of corruption slightly decreased. The most spectacular decrease in the level of corruption was reported in Georgia. Other significant decreases in corruption were also reported in the Balkan countries such as FYR Macedonia, Croatia, Serbia and Bulgaria.

Figure 4. Changes in corruption levels in particular post-communist countries

Corruption persistence in post-communist countries

In this section, we study the stability of corruption patterns in the post-communist countries using the Markov Transition Matrix (MTM). The MTM is a square matrix that contains the probabilities of moving from one state to another state. The use of MTM has gained popularity in social sciences, especially in economics to study the long-run world distribution of income among various groups of countries and to identify “growth miracles” and “growth disasters” (Jones, 1997). By analogy, in our study we can identify “corruption miracles” and “corruption disasters” and study the long-run distribution of corruption among the post-communist countries.

For the purposes of our study, the post-communist countries were assigned to four different corruption categories: high, medium high, medium low, and low corruption. The categorization was carried out for the sample of 27 post-communist countries, which were divided into quartiles. Therefore, this categorization was based on the entire distribution of post-communist countries. We considered sixteen different types of transitions between these states, including staying in the same corruption category.

This corresponds to the 16 quadrants of the transition matrix. If the probability of moving from category i to a category j at a given one time step is:

$$\Pr(j | i) = P_{i,j}$$

The four-state stochastic matrix P is given by using these probabilities, where

$$P = \begin{pmatrix} P_{1,1} & P_{1,2} & P_{1,3} & P_{1,4} \\ P_{2,1} & P_{2,2} & P_{2,3} & P_{2,4} \\ P_{3,1} & P_{3,2} & P_{3,3} & P_{3,4} \\ P_{4,1} & P_{4,2} & P_{4,3} & P_{4,4} \end{pmatrix}$$

Since the probability of transitioning from state i to some state must be 1, this matrix is a right stochastic matrix, so that:

$$\sum_j P_{i,j} = 1$$

An initial distribution is given as a row vector V (presented in Table 2). A stationary probability vector π is defined as a vector that does not change under application of the transition matrix; that is, it is defined as a left eigenvector of the probability matrix, associated with eigenvalue 1:

$$\pi P = \pi$$

The Perron–Frobenius theorem ensures that every stochastic matrix has such a vector, and that the largest absolute value of an eigenvalue is always 1. In general, there may be several such vectors. However, for a matrix with strictly positive entries, this vector is unique and can be computed by observing that for any i we have the following limit,

$$\lim_{k \rightarrow \infty} (P^k)_{i,j} = \pi_j$$

where π_j is the j -th element of the row vector π .

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

This implies that the long-term probability of being in a state is independent of the initial state i . Thus, the system evolves, over time, to a stationary state. Intuitively, a stochastic matrix represents a Markov chain with no sink states, this implies that the application of the stochastic matrix to a probability distribution would redistribute the probability mass of the original distribution while preserving its total mass. If this process is applied repeatedly, the distribution converges to a stationary distribution for the Markov chain. This allows us to obtain the long-run distribution of corruption in the post-communist countries.

The calculated transition probabilities among particular states are reported in Table 1.

Table 1. Corruption level category transition probability for post-communist countries (Markov transition matrix)

Corruption level	quartiles for post-communist countries			
High	89.64%	09.89%	00.47%	00.00%
Medium High	10.25%	80.13%	09.62%	00.00%
Medium Low	00.16%	12.09%	82.79%	04.96%
Low	00.00%	00.00%	04.24%	95.76%
Corruption level	High	Medium High	Medium Low	Low

Source: Own estimation.

It can be seen from the transition matrix that the probabilities of staying continuously in particular quartiles are the highest relating to large persistence in corruption results. In particular, the probability of staying in the low corruption quartile is the highest and close to one while the probability of staying in the medium high quartile is the lowest and equal to 0.8. Among the highest probabilities of changing the quartiles are the probability of moving from the medium low to the medium high quartile equal to 0.12 and the probability of moving from the medium high to the high quartile equal to 0.10. This suggests that in the long-run we should expect corruption in the post-communist countries to increase. This can be seen in the

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

long run distribution of corruption in the post-communist countries shown in Table 2.

Comparing the initial and long run distributions of corruption in post-communist countries it can be seen from Table 2 that in the long run we should expect corruption to increase as the size of the high and medium high quartiles are going to expand at the expense of the medium low quartile. This result is not surprising given the fact that the probabilities of moving from the high and medium high levels of corruption to the lower levels of corruption are smaller than the probabilities of moving from the lower levels of corruption to the high and medium high levels. It seems that corruption levels are highly persistent across time. Some countries remain trapped in "corruption" traps characterized by pervasive corruption whereas others end up in high corruption equilibrium and stay there. Here, the important results concern the countries of the former Soviet Union, most notably Ukraine and Russia, which ascend in their corruption control in the mid-sample only to fall back to the lowest category.

Table 2. Initial and long-run distribution for post-communist quartiles

Starting distribution post-communist quartiles			
High Cor- ruption	Medium High Cor- ruption	Medium Low Cor- ruption	Low Cor- ruption
24.95%	25.42%	24.48%	25.15%
Limiting distribution post-communist quartiles			
High Cor- ruption	Medium High Cor- ruption	Medium Low Cor- ruption	Low Cor- ruption
26.45%	26.39%	21.73%	25.43%

Source: Own estimation.

The most interesting cases are of course countries that managed to cross the borders between the corruption groups. Here most notable examples of such countries are the cases of Georgia and Estonia, which managed to "jump" two categories. In both countries, a significant liberalization has taken place associated with the withdrawal of the state from regulation, however, this was joined with institutional reform relating also to judiciary and crime prevention. This mixture provided the best results. Third case of a significant improvement was Croatia, which in the observed sample was during accession to the European Union. This process required putting an

**Proceedings of the 8th International Conference on Applied Economics

anticorruption framework in place associated with significant deregulation of "national champions" - big state owned companies with significant market power in the local market.

Conclusions

Over two decades of the simultaneous political and economic transitions in the region, a dynamic market economy has emerged in some countries, yet in some nothing changed, and the boundaries between the state and the economy remained murky. In this article, we studied the stability of corruption patterns in the post-communist countries. Though a small positive trend is visible, it is mainly initiated by those post-communist countries that joined the European Union. In general, we should not expect radical changes in the levels of corruption in other countries. On the contrary, corruption in the long run in the post-communist countries may even increase. Nevertheless, the story of an overwhelming majority of the post-communist countries is staying on approximately the same corruption level.

A possible explanation for this is that "corruption corrupts". The expected profitability of engaging in a corrupt transaction relative to not engaging in it depends on the number of other people doing the same. Gain from being corrupt from the point of an individual depends on how many other individuals in the same organization or society are expected to be corrupt. This is so for many different reasons:

- It is harder to seek out and punish corrupt officials in environments where everybody is corrupt.
- Corrupt individuals prefer to interact with other corrupt individuals and continue to be corrupt if they have interacted with corrupt individuals in the past.
- The reward to rent-seeking relative to entrepreneurship is high in societies where most individuals seek rents and accept bribes.
- Internalized moral feelings of guilt by fraudulent behavior decrease as the number of corrupt officials increases.
- The stigma and reputation costs associated with breaking social norms are higher in a situation when few other staff members are corrupt.
- Officials act upon a social convention arising under the assumption that they tend to imitate relatively more rewarding behaviors either by learning from experience in dynamic interactions or by progenitors transmitting their strategy to their progenies.

Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

Each of these mechanisms has the potential to make corruption self-reinforcing and to generate multiple equilibriums whereby organizations or countries with the same characteristics can experience very different corruption levels. This gives a role to history as a major determinant of corruption and explains its persistence. Countries can be “stuck” in density dependent equilibriums; the level of corruption in a country moves towards either a high or a low equilibrium depending on the initial situation. However, this setting leads to density dependant effects: i.e., critical population thresholds, which separate equilibriums with low levels of corruption from equilibriums with high levels of corruption. The presence of multiple equilibriums in turn raises the possibility of moving from a current “bad” equilibrium to one that is socially superior. This suggests that a ‘big push’ strategy is needed to reduce corruption levels in societies where corruption is pandemic. The question of how to make such a move has apparently not received much attention other than reports of various institutions. We know only that some countries remain trapped in the bad equilibrium and that radical action is needed, but what exactly should be done is not exemplified in the literature. This shows pathways for further research on causes of post-communist corruption. An interesting extension of the current research would be to study the effects of European integration on corruption in the post-communist countries.

**Income Tax Exemption as a Regional State Aid
in Special Economic Zones and its Impact Upon
Development of Polish Districts**

JEL Classification: *H25; H32; R11; R58*

Keywords: *regional state aid; special economic zones; regional development; poviats in Poland; public support*

Abstract: Special Economic Zones (SEZs) were established to attract entrepreneurs to invest in Polish regions in order to increase their social and economic development. One of the most important incentives offered in SEZs is state aid in the form of an income tax exemption. The objective of this paper is to verify if the intensity of regional state aid granted to entrepreneurs in SEZs has had a positive impact on the social and economic development of Polish *poviats* (a *poviat* is an administrative district). The public aid was received by beneficiaries when they made some profits and, instead of investing, used a tax allowance to decrease their tax base. However, part of the positive outcome of economic activities envisioned in SEZs should be the development of existing businesses and the emergence of start-ups, as well as the improved attractiveness of the region and the inflow of new investors (which should be manifested by an increase in the gross value of fixed assets per entrepreneur and a decrease in the unemployment rate at *poviat* level). The conducted research allowed for the conclusion that regional state aid in SEZs in the form of an income tax exemption was of a relative higher importance to the poorest regions (higher share in the amount of regional state aid), while its significance was much lower in better developed areas in Poland (lower share in the amount of regional state aid). The year-to-year study showed no relation be-

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

tween state aid granted in SEZs and an increase in GVFA per company or a decrease in the unemployment rate. However on the basis of analysis of the cumulated value of state aid in SEZs for the whole period from 2005 to 2013, we can say that regional state aid in the form of an income tax exemption in SEZs had a positive influence mainly in poviats located in the poorest voivodeships.

Introduction

Special Economic Zones (SEZs) were established in Poland based on the Act of 1994. However it should be underlined that they consist of many subzones created under the Council of Ministers Ordinances. According to available data, they were localized in 151 towns/cities and 217 gminas (townships) at the end of 2013 (UOKiK, 2014). This means that there were 368 subzones in Poland. This was an effect of an evolution of changes in areas and borders (as new plots were either included or excluded from them).

The main goal of the SEZs was regional development, deriving from an inflow of investors and the creation of new jobs. Due to the lower level of development of certain Polish regions and their poor quality of infrastructure and labour force, a special investment incentive was offered in the form of an income tax exemption. Due to its character, it was not available to entrepreneurs in the most sensitive and risky period, i.e. during the investment process or the launching of economic activities (production) in the SEZs. It was accessible only when economic operators gained profits from their businesses in a given region.

Therefore income tax exemption in SEZs was classified as regional state aid. From the theoretical point of view it should be mentioned that there are two polar opposite arguments on the need for regional incentives. On the one hand, regional policy undertaken by nation should assist areas (and thus the populations therein) that are deemed to be in need of assistance by virtue of their poor levels of economic performance: an inappropriate spatial structure within a particular region may adversely affect its economic performance and reduce its ability to adjust to changes (Parr, 2014, pp. 2-5). One of the main goals of regional policy is not only to increase welfare levels in the problem regions, but also to lead to efficiency gains within the national economy: utilisation of unused resources in lagging areas and reduction of congestion and other negative externalities in the relatively prosperous regions (Hansen, 1965, pp. 7-8). An OECD report stated that fostering growth, even in lagging regions, is in the interest of national governments as it contributes to national output without hindering growth op-

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

portunities elsewhere (OECD, 2009, p. 17). Thus a particular place might require intervention from outside in response to two sets of market and government failures: (a) a place can be trapped in a vicious circle of inefficiency or social exclusion; and (b) there can appear agglomerations' effects, which are always the result of public as well as private decisions, the former consisting of the design of institutions which are tailored to places (Barca, 2009, p. XI, 18-19).

On the other hand, there are arguments against governmental interventions at the regional level. The Keynesian approach to economic policy would allow for tackling regional development problems deriving from market failure, while completely ignoring governmental failures. Thus regional policy that includes broad incentives for firms to locate in less-developed regions is flawed and doomed to failure, because these areas lack supporting infrastructure and face competitive disadvantages (Porter, 1996, pp. 88-89). It also opens up the very real possibility of competition among governments, both at the national and sub-national levels (Gray and Duning, 2002, p. 412). The degree of labour or infrastructure scarcity necessary to induce sufficient firms to move to the outlying regions would lead to a general price increase: (a) businessmen know better than any civil servant how to choose the most efficient, lowest-cost location; and (b) if they have to set up plants at other locations the loss in efficiency may be substantial (Needleman and Scott, 1964, p. 157-158, 160). It seems that this kind of instrument generates some increase in investment and directly subsidises some output. However, only when the substitution of public for private funds has been completely eliminated, the private sector contribution to investment can be increased above the without-subsidy level, and assistance can act as an incentive to attract private funds (Wren, 1996, p. 535). In the end it seems that the taxpayers' money should not be used to subsidise private firms, and that companies themselves should decide on the most efficient location for their business (Armstrong and Taylor, 1999, pp. xiii-xiv). Thus, referring to the OECD report, any interventions should be evaluated against other uses of public funds (OECD, 2009b, p. 53).

There is a great deal of research into the factors determining investors' decisions in Poland generally, as well as in special economic zones (IBNGR, 2014). Thus in this study we do not discuss if the financial incentive in SEZs was attractive to entrepreneurs and what was its position in a ranking of the most important location factors to invest both in Poland and in SEZs. The objective of this paper is to verify if the regional state aid

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

granted to entrepreneurs in SEZs had a positive impact on the social and economic development of poviats in Poland.

The impact on a regional development was studied by analyzing changes in the gross value of fixed assets (GVFA) per entrepreneur and the unemployment rate in the period of 2005-2013. It is assumed that state aid in the form of an income tax exemption was granted to an entrepreneur when a company gained profit due to operating its business within the framework of special economic zones. A positive outcome of economic activities in SEZs should be accompanied by the development of existing businesses through new investments and the emergence of start-ups, as well as in an improved image and attractiveness of the region and an inflow of investors not necessarily interested in the allowances offered by SEZs (which should be manifested by an increase in GVFA per entrepreneur). A greater involvement of manufacturing and service businesses in the region should increase the demand for labour and, consequently, stimulate the labour market (which should be reflected in a drop in the unemployment rate).

Methodology of the research

The data relating to selected indicators of regional development (gross value of fixed assets per entrepreneur and unemployment rate at the poviats level) comes from Local Data Bank of the Central Statistical Office (GUS). Data concerning state aid derives from the Office for Competition and Consumer Protection. It should be noted that there are many forms of granting regional state aid to entrepreneurs in SEZs, however this study covers only income tax exemption granted to entrepreneurs with a SEZ valid permission. Data concerning the size of investment in SEZs comes from entrepreneurs obliged to report them to the Ministry of Economy.

Research was conducted in poviats (NUTS 4) because recent studies for voivodeships (NUTS 2) have not enabled researchers to capture the impact of selected categories of financial public assistance (Ambroziak 2014b). While other research suggests that companies in SEZs attracted workers and suppliers from the poviats in which they were based or from their neighbouring areas (Ambroziak 2009).

In order to capture the potential impact of SEZs on selected indicators of social and economic development we conducted counterfactual impact evaluation, i.e. the comparison of achieved results with estimated outcomes which could have emerged in the absence of the intervention in the form of an income tax exemption in SEZs (European Commission 2014, Gertler et

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

al. 2011). This method should allow for verifying the assumed causal effect between the intervention - consisting of the functioning of SEZs and attracting investors – and the effects for the poviats measured by changes in indicators of regional development. To this end, we selected an experimental (treatment) group composed of poviats with enterprises in SEZs and a control group of poviats without SEZs.

Since the study was aimed at assessing the impact on social and economic development, poviats from both groups should be statistically equivalent: a) identically respond to intervention, b) be identically influenced by external factors and interventions, c) be identical when it comes to their characteristics. The first two criteria were fully met by all poviats in Poland. SEZs might be established anywhere in Poland without any location restrictions and there were no administrative regulations, which would change the position of individual poviats. However, the third condition concerning the homogeneity of characteristics was not met by all poviats due to unequal regional development and their location in a particular voivodeship (what meant differences in maximum ceilings on regional state aid – the highest level was available in the least developed voivodeships). To identify the subgroups of poviats within the experimental and control groups we took into account:

- their relative regional development calculated as GDP per capita in relation to the EU average in 2005 (since GDP data for NUTS 4 poviats were not available, we used the data for sub-regions NUTS 3, treating them as relatively close to the real-life situation in poviats);
- relative regional development level in the voivodeship (NUTS 2) where a given poviat is located (calculated as GDP per capita in relation to the EU average in 2005).

To eliminate statistical differences in regional development and in admissible aid intensity in SEZs (i.e. with respect to characteristic features) we applied the matching technique. This consisted in distinguishing and comparing analyzed data from poviats in experimental and control groups based on the 3-point regional development scale. The scale was used by the European Commission in its works on the regional aid map (Guideline 2006; Ambroziak 2014a). It included the following areas:

- where GDP per capita was not higher than 45% of the EU average,
- where GDP per capita was above 45% but not higher than 60% of the EU average,
- where GDP per capita was above 60% but not higher than 75% of the EU average.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

Finally, seven categories of poviats in Poland in each group (experimental and control) were identified (Box 1). It was also important to grasp the differences among poviats of the experimental group taking into account the average of state aid intensity in SEZs (counted as an average of the ratio of the value of state aid granted to entrepreneurs to their investments in SEZs). Taking account of the above indicator, we identified four subgroups within the experimental (treatment) group of poviats:

- where the average of state aid intensity in SEZs was not higher than 5%;
- where the average of state aid intensity in SEZs exceeded 5% but was not higher than 20%;
- where the average of state aid intensity in SEZs exceeded 20%
- where state aid was not granted in SEZs.

Box 1. Categories of poviats depending on the regional development of voivodeships, in which they were located

Categories of poviats reflecting their relative development and the development of voivodeships, in which they were located:

- I.1. poviat whose GDP per capita was not higher than 45% of the EU average located in a voivodeship whose GDP per capita was not higher than 45% of the EU average (191 cases); (classification: voivodeship I, poviat 1.; category: I.1. (cat. I.1.);
- I.2. poviat whose GDP per capita was above 45% but not higher than 60% of the EU average located in a voivodeship whose GDP per capita was not higher than 45% of the EU average (5 cases); (classification: voivodeship I, poviat 2.; category: I.2. (cat. I.2.);
- II.1. poviat whose GDP per capita was not higher than 45% of the EU average located in a voivodeship whose GDP per capita was above 45% but not higher than 60% of the EU average (97 cases); (classification: voivodeship II, poviat 1.; category: II.1. (cat. II.1.);
- II.2. poviat whose GDP per capita was above 45% but not higher than 60% of the EU average located in a voivodeship whose GDP per capita was above 45% but not higher than 60% of the EU average (22 cases); (classification: voivodeship II, poviat 2.; category: II.2. (cat. II.2.);
- II.3. poviat whose GDP per capita was above 60% but lower than 75% of the EU average located in a voivodeship whose GDP per capita was above 45% but not higher than 60% of the EU average (15 cases); (classification: voivodeship II, poviat 3.; category: II.3. (cat. II.3.);
- III.1. poviat whose GDP per capita was not higher than 45% of the EU average located in a voivodeship whose GDP per capita was above 60% but not higher than 75% of the EU average (25 cases); (classification: voivodeship III, poviat 1.; category: III.1. (cat. III.1.);
- III.2. poviat whose GDP per capita was above 45% but not higher than 60% of the EU average located in a voivodeship whose GDP per capita was above 60% but not higher than 75% of the EU average (15 cases); (classification: voivodeship III, poviat 2.; category: III.2. (cat. III.2.).

In addition we identified three groups of poviats which were not included in the study because they were individual cases and no comparative analysis was feasible:

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

- I.3. powiat whose GDP per capita was above 60% but not higher than 75% of the EU average located in a voivodeship whose GDP per capita was below 45% of the EU average; (classification: voivodeship I, powiat 3.; category: I.3. (cat. I.3.);
- II.4. powiat whose GDP per capita was above 75% of the EU average located in a voivodeship whose GDP per capita was above 45% but not higher than 60% of the EU average, (classification: voivodeship II, powiat 3.; category: II.4. (cat. II.4.);
- III.4. powiat whose GDP per capita was above 75% of the EU average located in a voivodeship whose GDP per capita was above 75% of the EU average; (classification: voivodeship III, powiat 4.; category: III.4. (cat. III.4.).

Explanatory note:

Numbering X.Y.: X – voivodeship category, Y – powiat category.

Classification: I/1 - GDP per capita not higher than 45% of the EU average (the poorest/the least developed voivodeships/poviats);

Classification: II/2 - GDP per capita above 45% but not higher than 60% of the EU average (less developed voivodeships/poviats);

Classification: III/3 - GDP per capita above 60% but not higher than 75% of the EU average (more developed voivodeship/poviats).

Source: own studies.

In the study we decided to apply the difference-in-differences approach. This consists in deducting the difference in the outcome before and after the intervention in the control group from the same difference in the experimental group, in order to estimate the impact of the intervention. The method allows for ignoring (a) constant differences in the performance of poviats resulting from the level of regional development (and investment attractiveness); (b) effects of external factors, which influence them; and (c) characteristics which are irrelevant or difficult of statistical observation. It also enables one to capture the effects which emerge in relation to the intervention in the experimental group (European Commission 2012, Gertler et al. 2011). Differences in changes in the experimental group observed in comparison to the changes in the control group were interpreted as the impact of regional state aid in SEZs on the development of poviats.

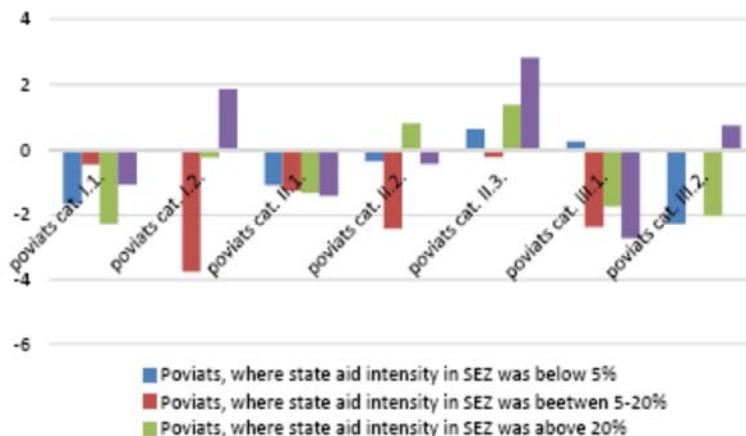

Regional state aid in special economic zones

Public aid granted in special economic zones is a type of regional state aid. The regional character of public assistance is revealed in goals and problems which are addressed, as well as in the territorial dimension of permissible assistance. It was permitted, under the EU law, if it was granted to assist the development of the most disadvantaged regions by supporting investment and job creation. Moreover it should promote the expansion and diversification of the economic activities of enterprises in the less-favoured

regions, in particular by encouraging firms to set up new establishments there (Guidelines 2006).

Regional state aid became one of the most important components of public support to entrepreneurs in Poland following its accession to the European Union. In 2005 it amounted 1,057 mln PLN, which represented about 9.1% of the total public support in Poland. In subsequent years, due to a huge inflow of EU funds and their distribution mainly to entrepreneurs in the poorest areas, the value of regional state aid increased to over 9,000 mln PLN, which constituted 54.3% of state aid in 2013 (UOKiK 2006, 2014). As regards public support in SEZs, its share in value of regional state aid has varied from 38% in 2005 through to 74% in 2007, when there was a break in the offering of EU funds, to 16% in 2013. The drop in the overall share was the result of the dramatic increase in the total value of regional state aid, not a decrease in public aid granted to SEZs (Figure 1.).

Figure 1. Changes in value, dynamic and share of regional state aid and public support in SEZs and in Poland

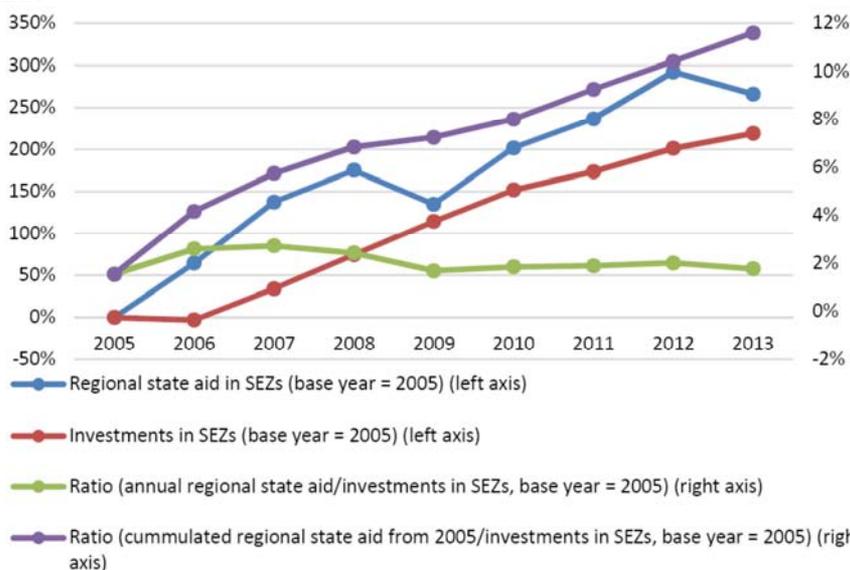

Sources: Own calculations based on data from the Office for Competition and Consumer Protection and the Ministry of Economy.

The annual value of state aid granted to companies in special economic zones grew from 406 mln PLN in 2005 to 1,488 mln PLN in 2013 (3.7 times), while in that same period the value of investments in SEZs at the end of the year increased from 26,455 mln PLN to 84,350 mln PLN (3.2 times). Both values rose in the three years after Poland's accession to the EU, while the value of public support decreased in 2009 as a result of economic crisis in the EU. In the next years, the value of public aid in SEZs

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

grew, with the exception of 2013, when it dropped slightly again. It is worth observing that on the basis of year-to-year analysis we can state that the relation of value of regional state aid to investments in SEZs reached 2.7% in 2007, then decreased to 1.7% and 1.8% in 2009 and 2010 due to economic problems in Europe, followed by a rather moderate increase in subsequent years (Figure 2.).

Figure 2. Dynamic of changes in the value and ratio of state aid and investments in SEZs

Sources: Own calculations based on data from the Office for Competition and Consumer Protection and the Ministry of Economy.

In order to evaluate the intensity of state aid in SEZs the ratio of cumulated state aid to investments in SEZs should be analyzed for the period 2005-2013. First, the value of investments in SEZs increased due to the inflow of new entrepreneurs, as well as the expenditures of existing companies within the SEZs every year. However at the same time it was also decreased as a result of either an outflow of investors or a closure of economic activities within the SEZ permits. Second, the cumulative amount of regional state aid granted to entrepreneurs in the form of an income tax exemption in SEZs increased every year, including when annual growth in value decreased in comparison to the previous year. Finally, we can observe that a relation between the value of cumulative state aid and invest-

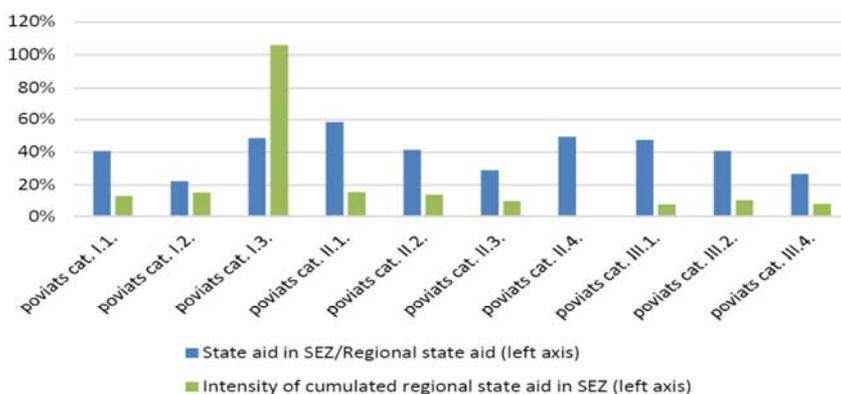

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

ments in SEZs increased on average by 1 percentage point yearly, from 1.5% in 2005 to 11.6% in 2013. This was the result of a lower dynamism of an investment inflow into SEZs in comparison to the cumulative amount of tax breaks granted to companies in SEZs. It seems that this trend is irreversible. First, all investors in SEZs are interested in benefiting from all admissible amounts of money available resulting from tax exemptions. Second, the period of functioning of SEZs was extended twice: to 2020 and recently to 2026, which still limits the investment attractiveness of SEZs to new entrepreneurs and reduces the opportunity to benefit from tax breaks for a longer time.

As regards regional distribution, the highest average ratio of public support in the form of an income tax exemption in SEZs to total regional state aid was observed (excluding the individual poviats classified in cat. I.3, II.4 and III.4) in poviats cat. II.1 (58.4%), III.1 (47.5%) and II.2 (41.3%) in the period of 2005-2013. The lowest level was reached by poviats cat. I.2 (22.3%) and II.3 (29.3%) (Figure 3.).

This means that regional state aid in the form of an income tax exemption in SEZs was of a relative higher importance in the least developed regions, while other sources and types of regional state aid (including more complicated to use EU funds) were more widely offered in the better developed areas in Poland.

Figure 3. Average ratio of state aid in SEZs to regional state aid and average intensity of cumulative regional state aid in SEZs in selected poviats in Poland in 2005-2013

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

The biggest nominal amount of regional state aid in the form of an income tax exemption in SEZs was granted to entrepreneurs in poviats cat. I.1, II.1 (c.a. 2,386 mln and 2,691 mln PLN) and in cat. II.2, II.3 (which reached half of those amounts) (Figure 4). The ratio of public support in SEZs to total regional state aid amounted to over 80% in poviats cat. I.1 in 2005-2007, and dramatically dropped to 25-40% in subsequent years. In case of the second group of poviats (cat. II.1), the share of state aid in SEZs to regional state aid lowered from the level of 60-70% to 26-38% in the period of 2005-2013. In case of poviats I.2, III.1 and III.2 one can observe that the cumulative amount of public support granted in SEZs was much lower (below 500 mln PLN), while the share of its annual value in regional state aid dramatically changed in the period 2005-2013. This means that entrepreneurs in poviats at all levels of development, but located in a more developed voivodeship, where the share of public aid in SEZs in total regional state aid was the lowest, received regional public support mainly outside the framework of special economic zones. Probably the majority of this assistance came from EU funds, which are much more complicated to use, but available immediately. At the same time, companies from the poorest and less developed regions got relatively much more assistance from the national budget through tax exemption in SEZs, which however was offered after the investment period and depended on profit from sales of goods and services produced in SEZs.

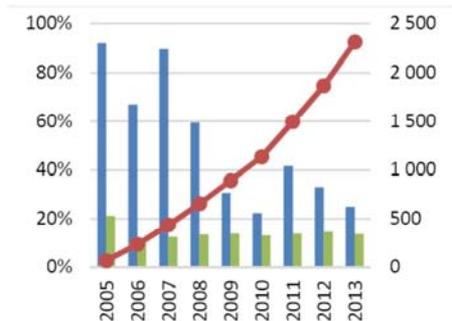

As it was stated earlier, the amount of state aid available to each entrepreneur in the SEZs depends on three factors: (a) the date of receipt of permission (if it is before 2001, then the rules concerning regional state aid intensity do not apply); (b) the investment localization according to voivodeship (different ceilings on regional state aid for different voivodeships); and (c) the amount of capital invested by an entrepreneur in a given SEZ. The highest average intensity (counted for each entrepreneur without considering date of receipt of permission to conduct economic activities in an SEZ) was observed in poviats cat. II.2 and II.1, I.2, and I.1, where the average intensity was estimated at the level c.a. 14-16% (Figure 4). This intensity level was much lower in poviats cat. III.2 (10.7%) and only half in the case of the other poviats cat.: II.3, III.1 and III.4.

Thus the highest average intensity of state aid in the form of an income tax exemption in SEZs was recorded in poviats from the least and less developed voivodeships, where the ceiling on the aforementioned admissible regional state aid was the highest, while in case of the more developed voivodeships, where the ceiling on admissible regional state aid was lower, the intensity was about half. However, it should be underlined that this does not mean that ceilings on regional state aid matters in this regard. Until now there are only a few cases of companies which reached the maximum ceiling of admissible state aid in SEZs. Thus, in the case of almost all entrepre-

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

neurs, the average intensity of granted state aid in SEZs was much below the acceptable thresholds at the end of 2013.

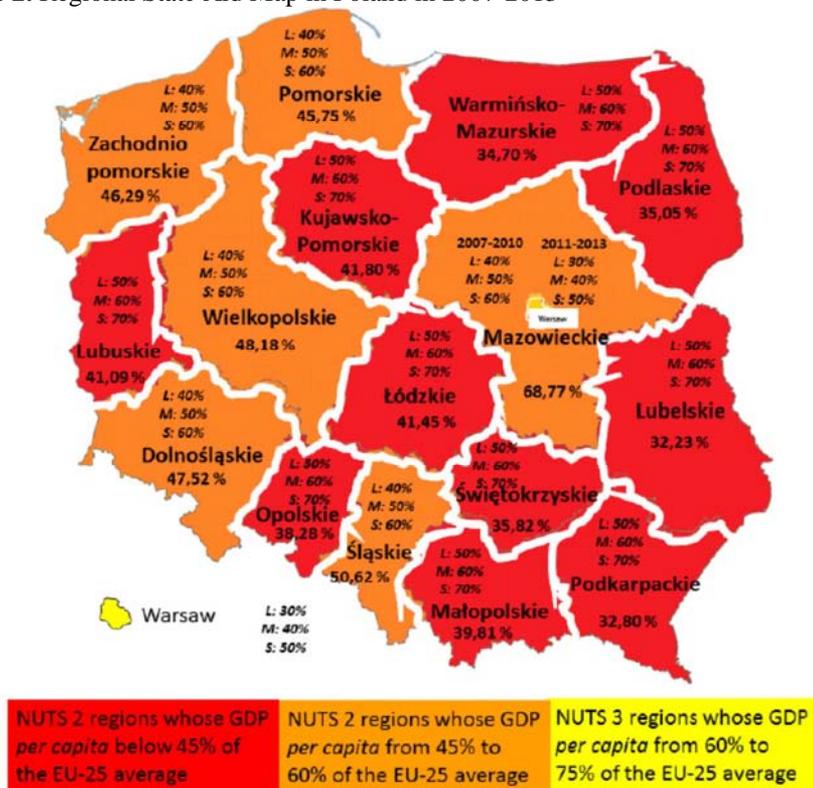

This means that differences in the intensities of state aid in SEZs among poviats depended on the value of investments located in SEZs. It confirms the conclusion of the previous research (Ambroziak 2015) that a relatively higher value of capital was invested in SEZs established not only in the poorest regions, but also in the slightly more developed regions of Poland (i.e. less developed, in contrast to the poorest and more developed regions) (Maps 1 and 2).

Map 1. Average intensity of regional state aid in SEZs in 2005-2013

Source: Own studies based on the Office for Competition and Consumer Protection and the Ministry of Economy.

Map 2. Regional State Aid Map in Poland in 2007-2013

Impact of regional state aid in special economic zones upon gross value of fixed assets in companies

As was already stated, regional state aid in special economic zones has a specific character and mechanism of receiving, and thus influencing, a region's economic and social development. Since it is granted in the form of tax exemptions from income tax, it is noticeable to entrepreneurs only after the period of investment and during the regular operation of a business in SEZs. Thus lower tax liabilities should (a) allow entrepreneurs to increase their investments; and (b) attract external capital to territories located next to SEZs (however e.g. within this same powiat). Therefore one of the measures of the impact of regional state aid granted in special economic

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

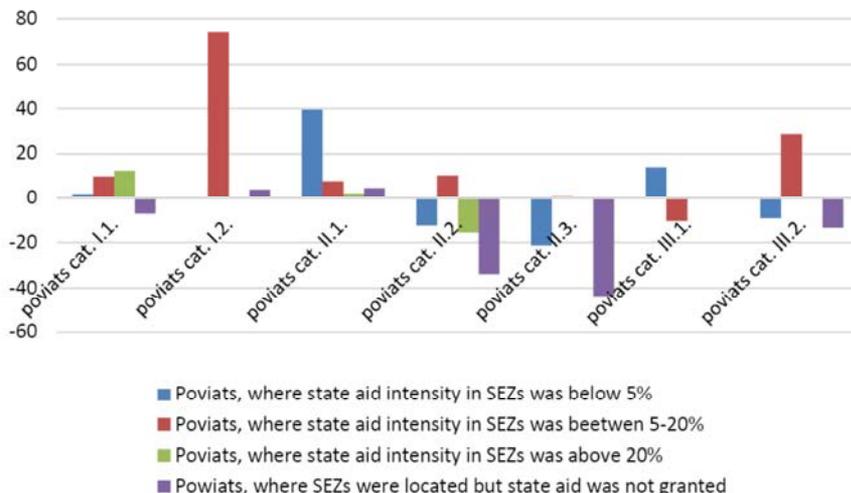

zones upon the regional development of poviats is the change in the gross value of fixed assets (GVFA) per company, which identifies the directions and dynamics of their development. Changes in the GVFA per company result from investments not only within SEZs but also from, inter alia, the general situation in the country, voivodeship and poviat, the quality of economic, legal and administrative environment, infrastructure and labour. To eliminate the impact of these factors and to reflect solely the impact of regional state aid granted within the framework of SEZs on the gross value of fixed assets in companies, we divided poviats into categories reflecting the level of their regional development and that of the voivodeships in which they are located. To this end we:

- compared the ratio of average gross value of fixed assets per company in 2013 to that of 2005 in (a) poviats in the experimental group and in (b) poviats in the control group (without SEZs), broken down by levels of regional development (calculated as GDP per capita in relation to the EU average) and, in the case of the experimental group, also by average of the intensity of regional state aid granted in SEZs in poviats;
- compared the average year-to-year change in the average gross value of fixed assets per company for subsequent years between 2005-2013 in (a) poviats in the experimental group and (b) in poviats in the control group (without SEZs) broken down by levels of regional development (calculated as GDP per capita in relation to the EU average) and, in the case of the experimental group, also by the intensity of regional state aid granted in SEZs in poviats;

In the period of 2005-2013 the highest increase in gross value of fixed assets per entrepreneur in comparison to the control group (without SEZs) - was recorded in poviats cat. I.2 (Figure 5). Taking into account the cumulative values of state aid and GVFA per company at the end of 2013, one can say that poviats with an intensity of state aid in SEZs ranging between 5-20% were the biggest contributors to this growth. However, this is only a statistical effect, because the highest annual growth was observed in 2007, 2008 and 2011 in poviats where state aid in SEZs was not granted. Only in 2012 was a noticeably bigger increase in GVFA per entrepreneur observed in poviats where the intensity of state aid in SEZs ranged between 5 and 20% in comparison to the control group. Then, in 2013 the increase in GVFA per entrepreneur in poviats cat. I.2 was dramatically smaller than in poviats without SEZs (Figure 6).

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

Figure 5. Changes in gross value of fixed assets per company in poviats with SEZs by categories, compared to poviats without SEZs, in 2005-2012 (in p.p.)

Source: Own studies, Office for Competition and Consumer Protection, Local Data Bank of GUS and the Ministry of Economy.

Also a higher increase in GVFA per entrepreneur in comparison to control group was observed in the period of 2005-2013 in both poviat categories: II.1 and I.1 (from the poorest voivodeships) (Figure 5). In case of poviats cat. II.1, the aforementioned increase was observed in poviats where average intensity of regional state aid in SEZs was below 5%. However, the highest increase in annual change of GVFA per company was noted in 2007, and in subsequent years in poviats with a low intensity or with SEZs where state aid was not granted. It should be noted that this outcome partially resulted from the different starting levels of GVFA in the poorest and in the best developed regions: the lower the original value the higher change in GVFA per company (Figure 6).

As regards poviats cat. I.1, where the average intensity of state aid in SEZs was above 5%, they recorded a higher increase in GVFA per entrepreneur in comparison to the control group in the period of 2005-2013. The highest increase in GVFA per company compared to results in the control group was noted in 2007, 2010 and 2011, thanks mainly to the poviats where state aid was granted in SEZs with an intensity even above 20%. It is worth underscoring that although the total amount and intensity of regional state aid in SEZs grew, there was a smaller increase in GVFA per entrepreneur in comparison to the control group in 2012-2013.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

As regards poviats II.2 and II.3, located in the less developed (in contrast to the poorest and more developed) voivodeships, a smaller increase in GVFA per company in comparison to the control group without SEZs was recorded in the period of 2005-2013. During that time one can observe a high fluctuation of their position vis-à-vis poviats without SEZs. In 2007, both poviat categories recorded higher increases in GVFA per entrepreneur in comparison to the control group. The main contributors of this success were poviats where state aid intensity did not exceed 20%, moreover there were also areas where SEZs were established but no state aid was granted. In subsequent years, the annual increase of GVFA per company was smaller in those poviats (regardless of the intensity of granted state aid) compared to areas without SEZs.

A similar situation was observed in poviats cat. III.1 and III.2, located in more developed voivodeships. As regards poviats cat. III.1, in the whole period of research, with the exception of 2009-2011, the increase in GVFA per company was smaller compared to poviats without SEZs. It is worth noting that this situation was observed also in poviats where the intensity of regional state aid in SEZs was above 5% and sometimes even above 20%. Referring to poviats III.2 one can observe that, in comparison to regions without SEZs, there was a higher growth of GVFA per entrepreneur in 2005-2007 and in 2011, and lower in the other years of the period covered by the study. This concerned all types of poviats cat III.1 and III.2, both those where the intensity of regional state aid was above 5% and even 20%, and those where state aid in SEZs was not granted.

Summing up this part of the study we can state that the poorest poviats, with SEZs located in the poorest and less developed voivodeships, recorded the biggest increase in GVFA per company compared to poviats without SEZs. It is worth noting that the aforementioned growth was observed in regions with a higher average intensity of state aid granted in SEZs. An increase in GVFA per entrepreneur in the less developed (but not the poorest) and more developed poviats with SEZs located in less developed voivodeships was smaller compared to poviats without SEZs.

Impact of regional state aid in special economic zones on the unemployment rate

Special economic zones were established in Poland in order to, inter alia, decrease the high level of the unemployment rate observed in the mid-1990s. Therefore in this study we wished to verify whether regional state aid in the form of an income tax exemption, which should increase the attractiveness of regions to other entrepreneurs, assisted in reaching the aforementioned goal. To this end we:

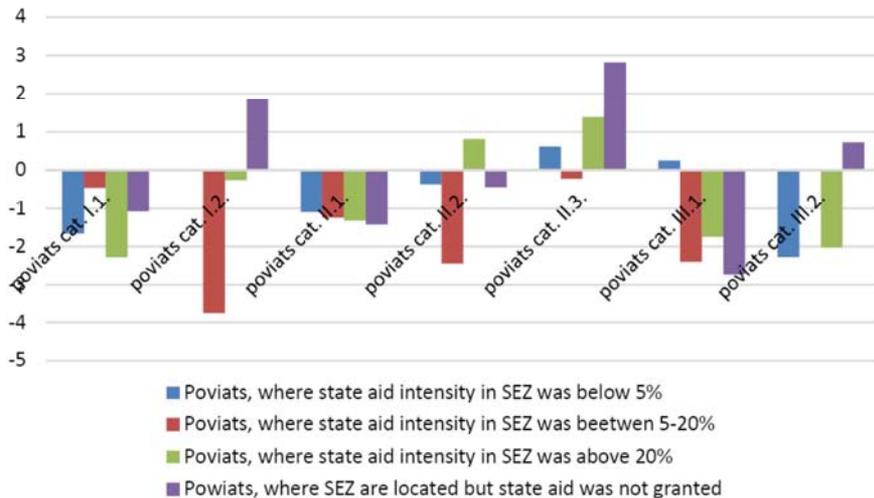

- compared the ratio of the unemployment rate in 2013 to that of 2005 in (a) poviats in the experimental group, and in (b) poviats in the control group (without SEZs), broken down by levels of regional development (calculated as GDP per capita in relation to the EU average) and, in case of the experimental group, also by intensity of regional state aid in SEZs;
- compared the year-to-year change in 2005-2013 of the unemployment rate in (a) poviats in the experimental group, and (b) in poviats in the control group (without SEZs), broken down by levels of regional development (calculated as GDP per capita in relation to the EU average) and, in the case of the experimental group, also by intensity of regional state aid in SEZs.

The highest reduction in unemployment compared to areas without SEZs was reported in the poorest poviats from all categories of voivodeships (cat. I.1, II.1 and III.1). The influence of poviats with SEZs on reducing the unemployment rate depended on their regional development and the intensity of state aid granted in SEZs: the poorest poviats (in terms of GDP per capita) with a higher intensity of state aid in SEZs were observed to achieve some reduction in their unemployment rate (Figures 7. and 8.).

In the less (in contrast to the poorest) developed poviats, cat. I.2, II.2 and III.2 from all categories of voivodeships, the total unemployment rate was also reduced much more in comparison to the control group. However it should be noted that there were regions in the experimental group which recorded worse results in comparison to those of poviats without SEZs. This concerned poviats I.2 and III.2 from the experimental group where regional state aid was not granted in SEZs, as well as poviats cat. II.2 with an intensity of state aid granted in SEZs above 20% of investments. As regards all other regions, the only category of poviats where the control group recorded a bigger reduction of unemployment rate than the experimental group was cat. II.3.

Source: Own studies, Office for Competition and Consumer Protection, Local Data Bank of GUS and the Ministry of Economy.

It is worth noting that by analyzing the year-to-year situation of all the above-mentioned poviats it can be observed that there was no common pattern or relation between the intensity of regional state aid granted in the form of an income tax exemption to entrepreneurs in SEZs and a reduction of the unemployment rate. This means that the intensity of state aid in SEZs did not matter in this regard on a yearly basis. In all poviat categories under study, despite a higher intensity of regional state aid in SEZs was recorded (with the exception of cat. I.1, II.1 and III.1), there were years when the reduction in the unemployment rate was higher in poviats without SEZs.

- Poviats, where state aid intensity in SEZs was below 5%
- Poviats, where state aid intensity in SEZs was between 5-20%
- Poviats, where state aid intensity in SEZs was above 20%
- Poviats, where SEZs were located but state aid was not granted

Source: Own studies, Office for Competition and Consumer Protection, Local Data Bank of GUS and the Ministry of Economy.

On this basis we can say that the biggest and most unambiguous reductions in the unemployment rate were recorded in the poorest and less developed poviats, where the intensity of granted state aid could have a much more significant indirect impact on the labour market. These poviats were from all types of voivodeships, which suggests that the ceilings on regional state aid have not had any impact yet. Partially this was the result of the

higher level of basic unemployment rates in the poorest and less developed poviats.

As regards the intensity of state aid in SEZs, it cannot be excluded that a future increase in the value of regional state aid in SEZ and a smaller inflow of investments to SEZs could lead to a decrease in the importance of the relation between intensity of state aid granted in SEZs and a reduction in the unemployment rate.

Conclusions

On the basis of the research into the relation between intensity of state aid in the form of a tax exemption granted to entrepreneurs in special economic zones and the regional development of Polish poviats, we can make some general conclusions:

- public support in SEZs, as a one of a kind of regional state aid, was of a relatively higher importance in the least developed regions, while other sources of regional state aid were more widely offered in the better developed areas in Poland;
- differences in the intensities of state aid granted in SEZs among poviats depended on the value of investments located in SEZs and were not related to the ceilings on regional state aid in voivodeships established in EU law;
- the poorest poviats with SEZs located in the poorest and less developed voivodeships recorded the biggest increase in the gross value of fixed assets per company compared to poviats without SEZs;
- there was a link between changes in the GVFA per entrepreneur, the intensity of state aid granted in SEZs, and the level of regional development of poviats: a higher average intensity of state aid was granted in poviats with lower regional development, and a bigger increase in GVFA per company was observed compared to poviats without SEZs;
- the biggest and most unambiguous reduction of the unemployment rate was recorded in the poorest and less developed poviats with the highest intensity of granted state aid in SEZs;
- the ceilings on regional state aid established in EU law did not have any impact on changes in the gross value of fixed assets per company or the unemployment rate in the period 2005-2013; however, it cannot be excluded that a future increase in the value of state aid in form of an income tax exemption in SEZs and a smaller inflow of investments into SEZs will lead to a decrease in positive relations between intensity of

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

state aid granted in SEZs and (a) increases in GVFA per entrepreneur;
(b) reduction of the unemployment rate.

Summing up, we can observe that the intensity of regional state aid granted to entrepreneurs in SEZs had a positive influence on the social and economic development of the poorest and sometimes less developed poviats in Poland, while the more developed poviats with SEZs did not record better or much better results compared to poviats without SEZs. The lack of certainty concerning the future of SEZs in Poland can stop the inflow of new investments, thus reducing the positive impacts of special economic zones vis-à-vis the value of state aid granted to existing investors in SEZs. This proves the common and well-known statement that one governmental intervention (i.e. setting up of special economic zones in 1994) leads to the next intervention: the closure or extension of SEZs' activities.

**Evaluation of the Meat Industry Efficiency
in Poland, in the years 2000-2013 (Based on the
data of the Central Statistical Office)**

JEL Classification: *D4; L1; O130*

Key words: *food chain; efficiency evaluation; prices dynamics; meat products consumption pattern*

Abstract: The paper presents the synthetic results of research on the evaluation of efficiency of selected food industries in Poland, in the years 2000-2013. A dynamic approach was applied to the studies which were based on the analysis of prices of raw materials, meat products and product assortments of meat processing companies. The mechanism of prices impact on the efficiency of management was examined using the term "food chain" in the meat industry, which comprises: agriculture- food processing-consumers. The reasoning of the influence of micro and macro factors on the economic efficiency in the pursuit of sustainable development was applied in the study as well as theoretical knowledge. This was the knowledge on the price structure, the impact of internal transformations (changes) of enterprises on the level of prices of goods offered by them in the meat industry studied.

Introduction

According to M. Porter „... competitiveness of a particular company will be largely dependent on the four primary factors: 1. Available factors of production, 2. Demand factors, 3. Developing an appropriate industry

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

system (supporting and relating industries) of associated trades, 4. Conditions of creating, organizing and managing enterprises” (Goryń, 2009, p.72).

The efficient use of productive resources – competitiveness (competitive ability) of the economy depends not only on production factors that the economy has, but also on its efficient use, while the chance to hold the ability to compete depends on the efficient use of production resources.

Growing competition in respect of certain resources leads to shortages and price increase, which will have impact on the European economy. Resources should be managed more efficiently throughout their entire life cycle, from the time of their acquisition, through transport, transformation, consumption and waste disposal. The European Commission emphasizes the significance of “effective management of resources”. This means generating more value using fewer materials and a different method of consumption. It will reduce the risk of shortages and maintain environmental impact on our planet within natural frames. It is the overriding principle applicable to all natural resources, including food, timber, biodiversity, energies, metals, soil, water, mineral resources, air and land. More efficient management of resources in Europe will contribute to achieving the objectives of economic, social and environmental politics in an easier and less expensive way.¹

The Ministry of Economy has developed the strategy for innovation and efficiency of economy “Dynamic Poland 2020”. In this document efficiency is understood as maximization of effects using a specified number of resources or reaching the desired target by applying the smallest possible amount of resources (mainly capital, raw materials and material expenditures) or optimal allocated resources. Both increasing innovation and creating conditions for efficient operation and development of business activity is the key to raising the efficiency of management.²

Nowadays, the scientific problem in the field of efficient use of resources involves the evaluation of management not only at the level of a

single company or the entire economy, but also at the level of enterprises linked with one work theme.

In the literature the organizational form of such a linkage of companies was defined in the food sector as food supply chain.³

The aim of the research is to investigate the mechanism of price impact on the management efficiency of enterprises connected⁴ with one theme of work⁵ in a selected food sector in Poland, in the years 2000-2013.

Methodology of the research

The evaluation of management was based on the analysis of changes in the prices of raw materials and a selected assortment of the meat industry products. The data from the yearbooks of the Central Statistical Office (GSO) including the years 2000-2013, was used in the paper.

The food chain links in the meat industry included- agriculture, food processing, products distribution and consumers.

The assessment of the factor impact on the level of prices in the agricultural production was performed on the basis of indicators including farmlands in the years 2000, 2005-2013k ha; animal production (livestock) in the years 2000, 2005, 2010-2013 in Poland, thousand heads; animal production (pigs) in the years 2000, 2002, 2005, 2010-2013 in Poland, thousands heads; the dynamics of compound feeds prices in the years 2000, 2005-2013, for 1 decitonne; the dynamics of the average purchase prices of major agricultural products of animals for slaughter in the years 2000, 2005-2013, PLN/kg.

The analysis of prices of selected assortments of food processing was conducted on the basis of the meat industry by index: the dynamics of the retail prices of selected assortments of meat processing production in the years 2000, 2005-2013, PLN/kg.

The analysis of demand and production pattern of the meat industry was conducted by index: supply of certain consumer foods on the market in the years, 2000, 2005-2013, thousands tonnes.

The selection of indicators describing consumer behaviour included: the dynamics of household expenditure on meat consumption in the years

³ The study presents the food chain in the meat industry.

⁴ The study assumes that the enterprises can be formally and informally connected with various forms of organizations: business cooperation, horizontal or vertical integration.

⁵ The objects of work can include raw materials or materials, in this study it is meat, semi-finished products for manufacturing products.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

2005-2013, PLN per capita; average monthly household expenditure on raw meat, including poultry, cold meat and other meat products in the years 2005-2013, kg/per capita; meat consumption by the household in the years 2005-2013, kg/per capita; average monthly consumption of raw meat, cold meat and meat products by the household in the years 2005-2013, kg/per capita.

The evaluation of the food chain economic efficiency was carried out on the basis of knowledge on the economic theory of predictable and unpredictable, balanced and unbalanced inflation according to P. Samuelsson.

Theoretical knowledge on evaluation, value added in the structure of prices, and the influence of evaluation on the management efficiency

Nowadays, companies manufacturing products with higher value added will become a competitive force on the market.

The price structure includes intermediate consumption and value added.

Value added is the difference between the company gross proceeds from sales of its goods and services, and the sum paid for raw materials and to the external providers of services. In other words, the value added includes all the costs of all the efforts of the business activity and full compensation for them. All the measures the company put in the final product and the assessment of its efforts by the market are counted (Drucker, 1998, p.88).

Within the price structure one can distinguish intermediate consumption and value added. On the other hand, value added includes staff remuneration and social security insurance, depreciation, taxes and profit norm.

The analysis of the added value is necessary to find the optimal value of expenses in the form of remuneration. Value added as an economic category exists in business even when there is no tax on that value introduced by the state. Value added is the target, according to which a business entity is created. The company directs its activity to obtain a profit, but to achieve this goal it must generate value added (Немцов, Довгань, 2002, p.129).

The structure of value added: staff remuneration and social security; depreciation; taxes; profit standard.

Everything that is within the scope of business entity activity is the generation of value added (profit) on the basis of purchased materials, raw materials, energy and necessary services (intermediate consumption). In some types of activities one can generate new value from zero without purchasing essential material components or services.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

Added value must be sufficient to:

- remunerate the staff,
- depreciate the worn part of fixed assets to exchange them in the future;
- clear various types of liabilities;

The remaining part of value added should be sufficient to obtain the expected profit (НЕМЦОВ & ДОВГАНЬ, 2002, p.129).

The company cannot exert influence on the level of depreciation value, let us assume, and does not deduct it because of the fact that in the production processes or while providing services the fixed assets are constantly used. The company is required to make transfers to various funds according to established standards of deductions. No entrepreneur would like to resign from profit. Thus, there remains only one element that “allows itself” to be regulated and it is the expenditure on labour.

Therefore НЕМЦОВ and ДОВГАНЬ conclude that the level of remuneration of staff depends entirely on the level of added value generated in a month.

The amount of charged remuneration should not be higher than the level of value added allows you to do so. The level of remuneration can be increased only through increasing labour productivity.

The increase in productivity, apart from production growth, allows us to raise the average income and lower the prices of goods. The increase in productivity may release the necessary resources to finance collective units. It may also lead to a reduction in working time, without concomitant reduction in the total production (Bremond, 2005, p.313).

According to Mill’s theory of production labour „... profits from unproductive labour employment are simply transfers of income; unproductive labour force does not produce a net value added. He adds, however, that labour force services involving the acquisition of qualifications or the protection of property should be considered as productive. It is his purpose to demonstrate that the capital accumulation rate is the function of the contribution of labour force employed “productively” (Blaug, 2000, p.194).

The level of human labour efficiency should, to a large extent, affect innovations implemented in the company activities, and by contrast ... innovation under conditions of perfect competition must lead to lower prices and increased production volumes.

If demand is entirely flexible then the total proceeds from sales will grow and the employers will increase their consumption and investment expenditure. However, if the demand will not respond to lower prices, the consumers will have unused purchasing power, which they will be able to direct towards other goods (Blaug, 2000, p.201).

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

Measuring productivity is the only criterion by which you can actually assess the competence of the management board and compare the management of different organizational units within the company, and also of different companies. Productivity includes all the efforts which contribute to achieving the results, and excludes everything that the company does not control (Drucker, 1998, p.87).

Labour productivity growth at a given level of pay leads to a decline in unit costs and allows the company to improve its competitiveness by reducing the sales price or increase the profitability of the capital invested as a result of profit enlargement (Bremond, 2005, p.312).

Otherwise, when no productivity growth is observed at the level of individual enterprises, and the prices increase steadily, one should expect decrease in efficiency of management or decrease in management efficiency with simultaneous repeated distribution of income at the level of all players on the market (Table 1).

Table 1. Inflation effects conditional on balance and prediction factors

Two dimensions of the inflation losses		
Inflation	Balanced⁶	Unbalanced
Predictable	Inflation does not contribute to losses	Reduction of economic efficiency
Unpredictable	Re-distribution of income and wealth	Reduction in efficiency and Re-distribution of income

Source: (Sammuelson, 1995, p.360).

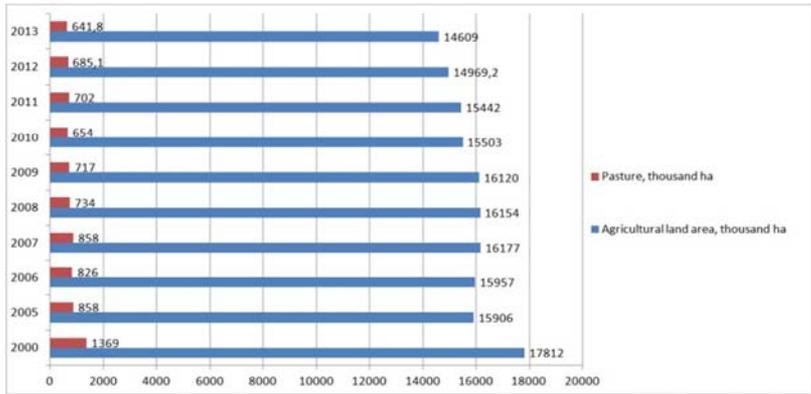

The cause-and-effect analysis of price changes in the food chain from raw materials to the final product

Agriculture. Since the year 2000 agricultural land area has decreased by 3203 thousand ha, in which pastures decreased by 727,2 thousand ha (Fig.1).

⁶ Balanced inflation – prices relations remain largely unchanged (all the prices grow at the same pace).

Source: the authors study based on the Central Statistical Office (CSO) data

According to the statistical data, CSO recorded an increase in compound feeds for porkers from 2000 to 2013- 1,81 times, for compound feeds for cattle- 2,32 times (Fig.2).

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

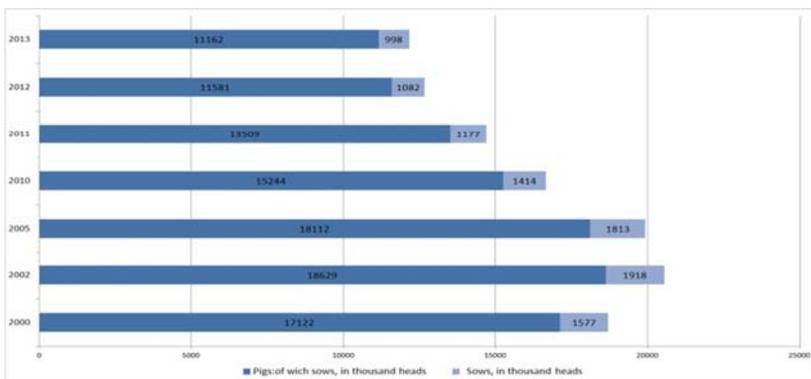

Figure 3. Animal output (cattle) in the years 2000, 2002, 2005, 2010-2013 in Poland, thousands of heads.

Source: the authors study based on the CSO data.

From 2000 to 2013 the headage of cattle decreased from 6088 to 5860 thousand heads (Fig.3). The headage of pigs considerably decreased from 17 122 thousand heads to 11162 (Fig.4).

Figure 4. Animal output (pigs) in the years 2000, 2002, 2005, 2010-2013 in Poland, in thousand of heads

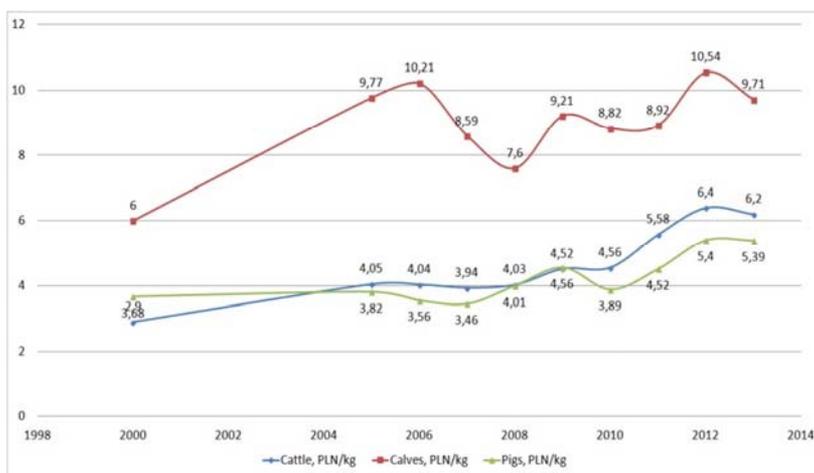

Source: the author's study based on the CSO data

Reducing the supply of animal output (cattle and pigs) caused fluctuation in purchase prices of agricultural products in the years studied. The

prices increased in 2013 in comparison to 2000 for agricultural products: cattle -1.68 times, calves-1.62 times and pigs- 1.86 times (Fig. 5).

Figure 5. Average procurement prices of major agricultural products of animals for slaughter in the years 2000, 2005 – 2013, PLN/kg

Source: the author’s study based on the CSO data.

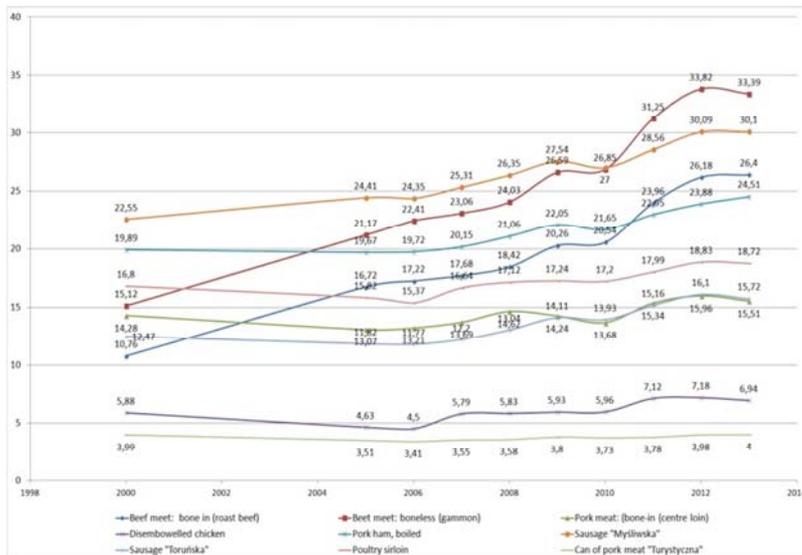

Meat processing. According to the data of the Central Statistical Office (CSO) the value of the fresh meat and meat products market (measured by the value of the sold output of the industry for this sub-sector) was in 2010 almost PLN 33.3 billion (while in 2005 it was 19 billion), which constituted about 30% of the value of the entire food sector. In the meat industry there operate more than 4000 companies.

The product range of large companies is quite diverse and includes more than 200 sorts of products. Expenditure on purchasing fresh meat and spices constitute 50% of the manufacturing costs. The growth of enterprises in this industry largely depends on the suppliers of meat.

Among the selected assortments (Fig.6) of the meat industry in the studied years 2000, 2005-2013 a general trend of increase in prices of these products was observed. The price of the canned meat “Turystyczna” was the only one that was reduced from PLN 3.99 in the year 2000 to PLN 3.98 in 2012, and in 2013 the weighted average price of this product was PLN4.

Figure 6. Dynamics of retail prices of major assortments of meat processing output in the years 2000, 2005-2013, PLN/kg

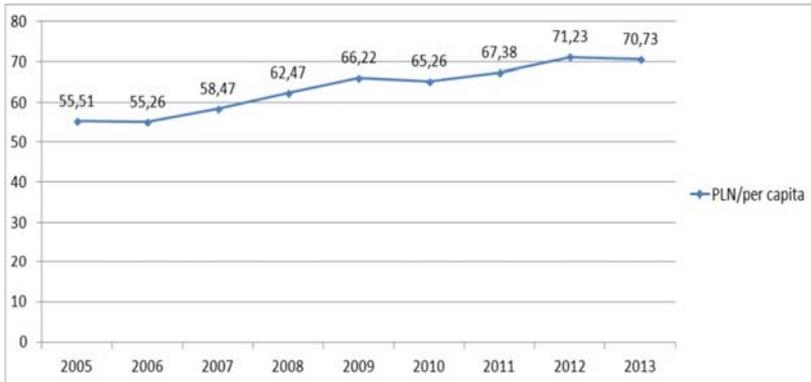

Source: the author's study based on the CSO data.

Consumer response to increase in production prices. Household expenditure on consumption of meat and meat products in 2005 was 55.51 PLN/per capita. The monetary value growth of expenditure was observed and in 2013 it was 70.73 PLN/per capita (Fig. 7).

Whereas the natural values (Fig.8) of monthly consumption of meat and meat products by a household in 2013 was 5.26 kg/per capita and in comparison to the year 2005 it dropped by 0.22 kg/per capita. The monthly pattern of expenditure and the pattern of consumption of meat and meat products by a household in the examined period is illustrated in Figures 9 and 10.

Changes in the output pattern. The pattern of consumer goods changed quite unfavourably for consumers. Consumers preferred to a larger extent less expensive products (canned meat and poultry). From 2000 to 2008 the consumption of processed meat products and slaughter animal offal, including cold meats, increased. From 2008 to 2010 the consumption of these products dropped and back in 2011 the consumption rose and in the subsequent years there was a fall in this output supply on the market.

Conclusions

Price is a very important signal of the market condition in terms of the products sold. An increase or decrease in prices and sales volumes of output indicates the market power of a particular company in the economic sector. Price analysis in terms of dynamics at different stages of economic processes in the examined food chain in the meat industry indicates an increase in the growth rate in the initial links (agriculture) and reduction in the rate of price increase in the final products (intended for sale to consumers).

In Poland, in the years examined every year the agricultural land area diminishes, including land used for grazing. Reduced profitability of the fragmented farms and higher prices of fuel, energy, and fertilizers determine the growth of compound feeds prices, which in turn is reflected in an increase in prices of raw meat.

Referring to the fact that meat consumption per capita has not increased, and a steady growth of prices of almost all assortments of the meat processing output (except for the canned pork meat "Turystyczna"), one can state that manufacturing companies of the industry studied face difficult operation conditions.

Synthesis of Pension System Parametric Assessment

JEL Classification: *H2*

Keywords: *old age security; cohesive testing; public pension; pension indicators; international standards.*

Abstract: Population aging and last decade economic circumstances are the factors the pension systems should overcome. Private pension scheme are making its low records worldwide but trying to keep necessary minimum level accrued rights for asset holders. Public pension PAYG scheme with its redistribution nature is still being the main bearer of the role of the old age income security. How to keep a national public pension system sustainable? The only prescription how to do it is a periodical renovation by testing the public pension scheme on (i) soundness and effectiveness within national financial and economic system, (ii) appropriateness of its organization and administration, (iii) compliance of parameters with international standards. Being steadily studied separately, each indicator can be easily discussed and described. But when we try to synthesize multi-factor analysis, then we are limited only by narrative conclusions and reports. To obtain more calculable and tangible results, and in order to make the analysis more attractive, in the research, it is applied empirical quantitative approach of econometrics as a tool that mediates between factor analysis and decision making for explaining old age security national indicators behavior. Paper is suggesting analytical system for assessing national pension system by applying new techniques of (i) the pension indicators evaluation and (ii) its values synthesis for the following indicators: existence of first public and funded pillars, inflation adjustment rules, salary growing adjustment, system adequacy and affordability, dependency ratio, length of service, retirement age. As an evaluation base there will be used international social security standards which are composed to cohe-

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

sive pension model (CPM) which consists of selected standardized indicators and its evaluation techniques. The model is tested to each pension system indicator and calculates its digital values. The values are resulted in the Cohesive Testing System index of the particular national pension system by applying CTS formula which is a linear equation.

Introduction

Pensions are still remain the main long term income replacement social benefit which perfectly reflects the social security main formula – the simple Fisher model which is a rational consumer choice over the citizen's life cycle (Barr N., 2001, pp.11-12). Over the time, and out of this macroeconomic question the old age security in the era of market and social changes becomes vitally important.

The main objective of the paper is to improve a public pension parametric analysis technique which is crucial for its further maintenance.

The research suggests standard mechanism of whole pension system parametric assessment and synthesis which makes a decision-making process more qualitative. The article presents the methodology of Cohesive Testing System (CTS) which is a new method of national pension systems indexing based on international standards of pension security.

The paper discusses two major methods of CTS system:

- Cohesive Pension Model (CPM);
- CTS Formula.

In the conclusion the CTS methods will be applied to the set of public pension systems of selected countries. Main pension indicators' values of the selected countries have been picked out from various articles and OECD statistical tables and quoted results and conclusions pertaining to the researched scope of pension systems.

Methodology

Cohesive Pension Model

Variety of pension parameters depends on policy choices but all of them aim at the goal of the income replacement in old age and the main composition of parameters of the pension systems and its behavior, in turn, falls under the more or less unique rules. Cohesive pension model of international standards is considered as a “scientific instrument” (Jos

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

Berghman, 1986, pp.34-39) which is used for assessment of national old age security system.

Not always the similar parameters may be appropriate for comparison each other in various countries. It's important to find common denominator and in our case these are international social security standards and quasi comparative method which compares different variables with common pattern. Cohesive Pension Model is designed as one of the important step of CTS system and consists of coherent international standards for the examined parameters of the pension insurance and on the next step the CPM is compared set of national pension parameters and reach CTS index. CPM is a set of international standards for the following basic parameters:

- qualitative parameters are scored “Yes” or “No” based on the pension pillars and methods of pension benefits indexation;
- quantitative parameters are replacement rate, contribution rate, amount of persons protected or dependency rate, length of service, retirement age and other quantitative parameters of national pension system which may be measured by scores based on its values.

The dependent variables in the formula are numbers of mentioned parameters in the Table 1 and each of them has their own rate in accordance with its values.

The result of final calculations is CTS index of national pension system which determines how close the national pension system parameters to CPM harmonized international standards.

CTS index allows decision makers and reformers to estimate the current situation and also to understand how to refine the system and how to increase the cohesion rate. The high cohesion means that pension system is compliant with international social standards and does have an indication of sustainability of a national old age security system due to assumption that CTS rating considers how much the main indicators are coherent with economic theory of social security and classical pension equation $sWL=PN$, where “s” is a pension contribution rate, “W” is an average real wage, “L” is number of workers, “P” is average pension, “N” is a number of pensioners (Barr, 2001, pp. 96-100).

Table 1. CTS set of indicators and its evaluation techniques

N	Items	Variable in CTS formula	Mean	Low values	High values
1	First pillar	k1	Yes/No	0(No)	20(Yes)
2	Second pillar	k2	Yes/No	0(No)	5(Yes)
3	Inflation adjustment	k3	Yes/No	0(No)	5(Yes)
4	Salary growing adjustment	k4	Yes/No	0(No)	10(Yes)
5	Adequacy (replacement rate)	k5	Rate	0 if $x < 40$	$10 + (x - 10)$
6	Affordability (Contribution rate)	k6	Rate	0 if $x > 30$	$10 - (x - 20)$
7	Amounts of persons protected (dependency ratio)	k7	Rate	0 if $x > 40$	$10 + (40 - x)$
8	Length of service	k8	Rate	0 if $x < 30$	$10 + (x - 30)$
9	Retirement age	k9	Rate	0 if $x < 60$	$10 + (x - 60)$

Source: own work.

CTS Formula

The data (metrics) we have discussed above are processed by our multi-factor cohesive linear variables statistic formula.

Statistical processing of the results is carried out using the factorial analysis with post comparison of values with international standards.

The formula is an ordinary linear equation with number of indicators and strengthened by adding a square root index of total value of quadratic equation of the k variables which were explained in detail within the previous chapter. Values of those variables have predefined intervals of scores as it is described in the Cohesive Pension Model in the Table 1 above.

The CTS quadratic equation is of the form:

$$c = \sqrt{\sum k_i^2}$$

where,

- c - CTS index;
- k - digital value of the metrics which represents pension indicator. Here $k=0$ as lower value and higher value of the indicator is calculated by using of the evaluation techniques in the Table 1;
- i - sequential number of indicator.

The empirical part

Based on the methodology described above, further we will go through the indicators and how CTS scores each of them.

Pension pillars

Pension pillars are the major indicators within CTS system. Classical definition of the first pillar is a pension system which organized publicly and by the principle pay-as-you-go (Nicolas Barr, 2001, pp 89-95), thus mainly covers major part of population and second pillar is various types of funded pension schemes. CTS considers that PAYG scheme is more reliable and can withstand pressures and overloads and more isolated from external shocks as it was shown during the recent 2008-2009 financial crisis and main reason of the relative stability is in the redistribution of social contributions.

On the contrary, the fashion of the latest decade, funded pension scheme, is experiencing hard times due to risky nature of the pension assets which are to be managed through unstable market. Since the recent financial crisis the funded pillars were diminished in certain extend in some countries we studied. Many countries now are restructuring of the management of pension assets and some countries significantly shrinking funded pension scheme parts due to uncertainty, lack of information and risks (or any of combination of these three factors) of financial market and its possible impact to actuarial insurance as adverse selection and moral hazard (Nicolas Barr, 2001, pp 13, 91-93, 100-122). CTS treats funded pillar as a supplementary scheme and considers that PAYG is more appropriate pension scheme due to its stability, coverage, endurance and sustainability.

Base on the opinion concluded above, the “first pillar” indicator, or public pension security system is reputed to be a guarantee of income security in old age and CTS scores a presence of national public pension system

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

with 20 score and, in turn, funded system is evaluated with lower rate of 5 score.

Benefits adjustment

Research shows that mainly the pension adjustment techniques rely on economic situation of countries. Most popular techniques are simple adjustment of pension amount to CPI index but as a consequence, the real value of the pensions will be gradually diminishing every year. On the contrary, wage growth indexation which is financially reasonable and viable is not used by many countries. Some countries invented hybrid techniques of pension adjustment when calculation is based on combination of “wage”, “contribution”, and even on other factors like sustainability. Few of them use annual or one off compensations, for instance, a compensation due to pension reforms which might cause actuarial decline of pension amounts.

Pension adjustment based on consumer price index (inflation) is a minimum level of pension amounts indexation, whereas wage based indexation allows to reach more higher level of benefit adjustment and CTS evaluates the former pension adjustment technique with score 5 and latter one with 10.

Pension benefits adequacy

Adequate replacement rate, first of all, protects low-income workers from the old age poverty (OECD, 2011, p.118) and the low income groups of insured people gain more from the public pension scheme than average and higher earners.

Pension adequacy is one of the major parameter of CTS and 40 percent of replacement rate which is a minimum promulgated by ILO Convention 102 “Social Security (Minimum Standards) Convention, is considered by CTS as a minimum threshold. The value that lesser than the replacement rate threshold is not regarded as an appropriate level of pension. Developing countries now is struggling to obtain the minimum standards but still it is remaining high plank. Usually, developing countries where ILO standards are not ratified establish own national standards which are smaller than the ILO minimum standards. European Union average varies around 60 percent and some countries traditionally pay more. Most recent European member States still have low level replacement rates of public pensions. World Bank experience generally stipulates that for employee with full

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

service length as an initial target of retirement income replacement (net of tax) from public pension insurance systems would be about 40 percent of the real earnings to maintain subsistence levels of income in retirement taking into account a general trend that the replacement rate of low income workers is higher than those who get high salary and by the opinion of World Bank experts the replacement rates above 60 percent is not viable when it is kept over the long period as it would require higher contribution rates and negative effect to economy (Holzmann Robert and Hinz Richard, 2001, pp. 55-57). Based on the World Bank position and also the on articles 28 and 67 of the ILO Convention 102, CTS evaluates with 10 score the adequacy is equal to 40 percent and adjusted by each additional value above 40 percent.

Pension system affordability

Pension system affordability or social contribution rates refer to the economic and financial capacity of the business, individuals and whole society and uses contribution rate indicator which is balancing the social security equation by N.Barr (2001) $sWL=PN$ regarding old age security. Mainly, contribution rates are actuarial instrument used by countries and apparently the rates depend on the budget of the public pension fund and CTS, on the contrary, calculates its “degree of actuarial fairness” (Eliza Baroni, 2007, pp. 13-28) and regarding the formula, it refers to the link between pension contributions and pension benefits and it can be equated as $(sWL/PN)-1=0$ and any nonzero probability does not provide actuarial fairness of the pension system. According to the equation the contribution rate is direct proportional to pension fund ($s=PN/WL$) and it obviously means that the more contributions the more pension fund. On the other hand, the contribution rate is in the inverse proportion to wages and labour force (WL) and it says about economic pressure to employers and employees, hence, high contributions negatively affect wages and entire state budget. It is consistent to the

World Bank indications, and CTS takes into consideration the 10 percent of pension contribution rate as a standard and “comfortable minimum” threshold for national economy and the rates higher than 20 percent of wage bill causes “direct” and also “indirect” costs of high social contributions through budget burden and higher incentives for evasions accordingly (Robert Holzmann and Richard Hintz, 2001, pp. 55-57). It makes CTS establish the indicator’s score with maximum reasonable threshold of 20 per-

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

cent of contribution rate and further adjustment within the interval of 10-30.

Dependency ratio

Dependency ratio will show the potential

Regarding dependency ratio standard, CTS applies ILO Convention 102 method of defining the norm of pension system coverage among active employees or among whole inhabitants. In accordance with Article 27 of the ILO Convention 102 a pension system should cover minimum not less than 20 percent of inhabitants or 50 percent of all employees. Also, it needs to be kept effective proportion of active population which is not less than approximately 2,5 active workers who pays social contributions to 1 pensioner (calculation was made in accordance with a statement in ILO Convention 102 where 50 percent of all employees is approximately 1/2 and CTS starts its assessment from 40 percent as minimum required dependency ratio) (ILO Convention 102, 1952). In our research it is used an economic old age dependency ratio which matters when a research deals with pension system sustainability (Woss J., 2011, pp. 66-68). The formula of the economic old age dependency contains inactive population related to active population.

Length of service

CTS treats length of service indicator standard by taking into account the requirement of the Article 29 of the ILO Convention 102 “a qualifying period which may be 30 years of contribution” (ILO Convention 102, 1952) and also minimum qualifying period which gives right citizens to be entitled to the state pensions. At the same time CTS is not concerning with various early retirement schemes which practically lead to additional deductions from pension amounts per pre-retirement periods (years, quarters or months) and this technique is actually grading and adjusting pension rights in accordance with the length of socially contributed service of citizen. Service length of 30 years will be scored as minimum rate 10 and every incremental year will increase the score accordingly.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

Retirement age

The ages are “situated between 60-65”, but some countries establishes “flexible retirement age” an one can be retired “in a larger time span” (Pieters Danny, 2006, pp. 51-58) and, according to this, CTS retirement age concept is: the more (lengthy) pension age the better a pension system and person as well as society would gain more from longer employment period. Though, in the Article 26 of the ILO 102 social security standards establish “65 years or such higher ... with due to the working ability of elderly persons in the country concerned” (ILO Convention 102, 1952), CTS flexible retirement age concept establishes 60 years as a necessary minimum and lesser retirement age is scored as zero and in turns score will be higher as the higher the retirement age will be beyond that minimum.

Conclusions

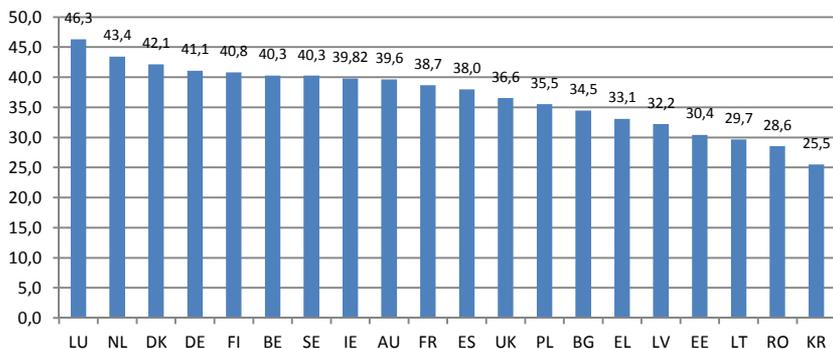

For cohesive testing, there were analyzed the old age security systems of selected countries by using open statistical databases (Eurostat database, 2014 and Pension watch, 2012) and applying CPM Model and CTS Formula. It resulted in CTS indices (see table below) and the following findings:

- Luxembourg, Netherlands, Denmark are leading the cohesive testing system range. Big group of continental countries Belgium, Germany, Austria, France and also Finland and Sweden composes stable CTS rates (which is considered to be 36,00 an higher).
- Post crisis measures of Ireland pension system which has tightened national pension system conditions brought necessary achievements and, as a result, Irish pension system is rated accordingly due to increased retirement age and length of service along with good perspectives in dependency ratio which may provide financial sustainability of public pension system in the future.
- Financial crisis dropped Greek pension system CTS rate by causing understandable negative effects to its adequacy.
- All indicators of EU recent new members Lithuania, Estonia, Latvia, Romania led by Bulgaria are quite low than studied countries with stable CTS rate. CTS brought these countries up the rare because of relatively high dependency rates, low service length which resulted in inadequate pension amounts level.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

- CTS calculations consider that universal pension system of United Kingdom is too liberal by having low level of required length of service and retirement age which resulted in low replacement although there is appropriate level of dependency of pensioners to active population (i.e. dependency ratio).
- Kyrgyzstan which is a single representative of Central Asia in the research, has a pension system which was updated during the post soviet period and poor economy affects pension system efficiency and CTS is equal to 25,5 is quite low.

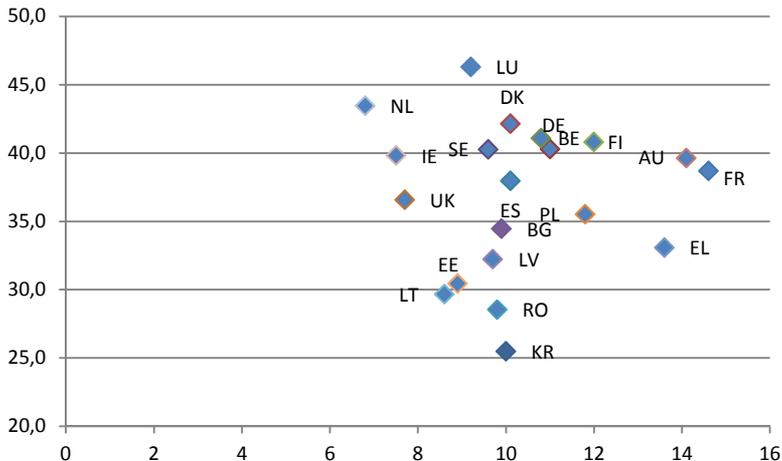

Figure 1. CTS index table

Source: own work.

CTS rates and public pension system expenditures dispersion shows that there is no correlation between them generally (correlation rate 0,014), which means that, in general, CTS rate doesn't depend on rates of pension expenditures in GDP.

Figure 2. CTS index table

Source: own work.

However, when we make analysis of various groups of countries separately, then we can observe a distinct dependency between the CTS rate and expenditures.

We ranged the pension systems in accordance with CTS rates and composed two groups of countries. First group contains CTS ratios less than 36,0 and represents mainly countries that join EU recently and their GDP size is lesser than other EU member states within studied scope. Second group consists of the EU developed Member States from both Atlantic and Continental Europe.

First group of researched pension systems' CTS rates depend on public pension expenditures and positive correlation, which is equal to 0,74, shows significantly high level dependency. It means that these countries' pension systems quality still relies on expenditures.

On the contrary, the rest of the studied countries, which are represented by EU developed Member States, have negative correlation rate -0,39 between CTS and pension expenditures and it means that in some developed countries a direct budget subsidies, in most cases, are not able to improve its CTS rates, and pension systems require more rational restructuring.

Based on the research we can make the following conclusions:

- A pension system synthesized CTS index helps to make comparative study in terms of international standards as well as to define an international rate of the pension system;

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

- The CTS results are logical and it generally fits with the main conclusions of other recent comparative researches of the EU Member States pension systems, but synthesized CTS index which composed from separately calculated values of pension indicators is more effective and results are more tangible, so that allows to look into the detailed indicators by using its digital values and, in turn, it simplifies analysis;
- CTS is economic index of a pension system and considers how much the main indicators are coherent with economic theory of social security which based on the classical equation $sWL=PN$, where “s” is a pension contribution rate, “W” is an average real wage, “L” is number of workers, “P” is average pension, “N” is a number of pensioners.
- Correlation of CTS indices and pension expenditures (in GDP) may show how far the expenditures are effective and consequently may define whether it should be done a rational restructuring of the pension system or it simply depends on budget subsidies.

**An Empirical Study on Students' Behaviour
Regarding Creative Accounting Techniques***

JEL Classification: *M41*

Keywords: *Creative accounting; ethics; risk propensity; student behaviour, International Financial Reporting Standards*

Abstract: The scope of this study is to investigate the accounting master students' attitude and perception regarding ethics and the existence and manifestations of creative accounting, in the context of harmonization of the Romanian accounting system. The sample of our research consists of accounting master student from three Romanian representative universities. Our survey regarding the students' perception on the accounting practices is a descriptive one, we have used as an instrument of research the questionnaire. These were posted on an Internet page

* This work was cofinanced from the European Social Fund through Sectoral Operational Programme Human Resources Development 2007-2013, project number POSDRU/159/1.5/S/142115 „Performance and excellence in doctoral and postdoctoral research in Romanian economics science domain”

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

and also, we used the possibility of its direct approach, preserving the anonymity of the respondent. In order to attain our research's objectives we have first presented a descriptive analysis of the answers, but tested some research propositions from a practical point of view as well. These show that there is a correlation between the master students' tendency (as potential managers) to modify the accounting information and to distort the real image of financial reports and their ethical behavior. We consider our study is valuable and attractive from the perspective of the elements of introspection and connection that it detects, in the context of a clear interest expressed by the authors in the students' psychology and their irrational behavior regarding their potential future decisions.

Introduction

Currently, accounting worldwide is facing irreversible processes such as: economic globalization of business, the internationalization of economic relations, development of transnational corporations and foreign capital investment. Accounting has sought to modernize, to continuously improve and evolve over time in order to meet the information requirements of the moment. Romanian accounting could not remain indifferent to the profound changes that have taken place in the economic field, considering the phenomena of harmonizing financial reporting of companies worldwide and the idea of adopting a common language for financial reporting in order to develop the level of comparability internationally. An important role in this respect is played by the emergence and continuous improvement of IFRS.

Order no.3055/2009 plays the strongest impact on the Romanian accounting. These regulations have been subdued to permanent improvements since the moment of issue until present time, adapting to the EU Directives and IFRS.

Trying to harmonize the accounting system to IFRS has not been easy. Ristea et. al. (2010, pp. 177-178) lists a number of specific features regarding the transition to IFRS such as: "the call for estimates and professional judgment, as reference elements of the basis of accounting solutions; introduction of the IASB framework as the conceptual framework of the Romanian accounting; the adoption of concepts from international standards which did not originate in the national practice, such as deferred taxes; introduction of new accounting principles such as the principle of economic primacy over law and the materiality threshold principle; the existence of deviations from the principle of balance sheet intangibility, a tradition accounting principle in Romania; application of cost / benefit ratio in the

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

process of obtaining financial-accounting information; the use of new assessment base, such as fair value, current value, etc.

Certain international accounting standards were easily assimilated into practice while for other parts was more difficult and some will have to take some preparation to be assimilated. A modern accounting system based on IFRS standards requires disconnection of accounting from taxation. Feleagă & Malciu (2002) in the content of an essay on the battle between the ideal of honest accounting and the "creative accounting" practices in the context of the Romanian economy, made a plea to disconnect accounting from taxation. Disconnecting accounting from taxation will not be easy to achieve because the state will not accept too easily to be on the "tail" of users of accounting information and in this situation the ad littera introduction of IFRS standards in the Romanian accounting environment is facing difficulties. The efforts made by the Romanian accounting standard setters in terms of assimilation of IFRS in the Romanian accounting environment is positive taking into account that the Romanian accounting can not remain indifferent to the processes of business globalization, the internationalization of economic relations, the development of multinational companies, of foreign capital investment and the development of information systems.

In a study by Iftime, A.D. & Ioan G.C. (2013) which aimed to investigate the perceptions of professional accountants on the costs, benefits and implications of applying IFRS in Romania concluded that 73% of respondents considered that the application IFRS financial statements would improve to a great extent the quality of financial information. Even if the Romanian accounting regulations have not kept pace with the changes in IFRS, yet accounting treatments and options of the Order no.3055 / 2009 are in most cases similar to those of IFRS. In the content of these Romanian accounting regulations are found a number of accounting options which involve several policies (in terms of bases, conventions, methods, rules or practices) and/or estimation techniques to solve the same problems, treatments that have a different effect on the financial position and performance of firms.

The results of a study conducted over the years 2010-2013 by Pășcan (2014) suggest that IFRS adoption in Romania generates an enhancement of accounting quality, registered especially in the case of information about the book value of equity.

Both accounting standards and Romanian Fiscal Code provides a number of degrees of freedom and flexibility All these make the Romanian

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

accounting regulations approved by Order no. 3055/2009 to provide sufficient opportunities for professional accountants call creative accounting techniques. Both accounting standards and the Romanian Fiscal Code provide a number of degrees of freedom and flexibility All these make the Romanian accounting regulations approved by Order no. 3055/2009 provide enough opportunities for professional accountants to call on creative accounting techniques.

Professional judgment is one of the basic concepts underlying the Romanian accounting system with accrual accounting and business continuity. The way in which this concept is understood causes the occurrence and temptation to creative accounting practices. In the context of today's Romanian accounting regulations, the professional accountant is decisively the dependent element: the manner in which he exercises in his professional activity this professional judgment. Coman, Diaconu & Gorgan (2008, p. 25) state that "the exercise of professional judgment must be made in the spirit of the objective of true image (fair accounting) and not in the vie of creative accounting use (bad accounting)."

Literature review

The temptations of creative accounting can be alluring and nothing undermines more seriously the trust in a system than the occasional impositions generated by creative accounting. As well know, creative accounting is not a new practical activity. It has been both a temptation and a problem since the accounting principles were used for the first time in order to draw up the financial reports on company performance. Throughout time, creative accounting has been the subject of numerous research studies, many researchers trying to provide a definition related to this concept. A complex vision of creative accounting is given by Naser (1993), according to which creative accounting is: "1) the process by which, given the existence of gaps in the rules, accounting figures are manipulated and, taking advantage of the flexibility, are chosen the measurement and disclosure practices which allow the transformation of synthesis documents from what they should be into what the mangers would like them to be; 2) the process by which transactions are structured in such a way as to enable "the production" of the desired accounting result. Raffournier (2003) defines creative accounting as "the use of flexibility and lacks in regulations to present the financial situation of the company in a manner different from that which would result from the ordinary application of the existing rules."

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

Tabără & Rusu (2011) believe that "creative accounting refers to accounting practices derived from standard accounting usage, characterized by certain, more or less complex creative accounting techniques, the ultimate goal being the change by the accounting information producers, for the desired purposes, of the financial position and the performance of the entity reflected in the financial statements".

Creative accounting is negatively perceived given that accounting professionals seek to apply those accounting policies in order to beautify the financial statements and the firm's performance. Dumitrescu (2013) does not exclude either the "positive alternative, in the sense of innovation that should lead to engineering able to answer the question: How to manage resources more efficiently, to build performance?"

Groșanu (2013) wonders whether the best solution is to use creative accounting in good faith or to prohibit some creative accounting techniques. According to the researcher, there is no answer that will lead to a permanent resolution of the problem since human society is particularly complex and there is always a fundamental disturbing factor that is the man. And man is subjective by nature. The accounting dictatorship might be a valid solution in this view. With the development of human society there are protection systems against viruses that affect society and hence accounts. Tabără & Rusu (2011) state that "creative accounting practices will disappear only with the disappearance of the causes that generated them, thus the accounting setters' desire to limit creative accounting must consider the circumstances that allow its expression."

The literature presents a number of assumptions according to which the entity's management chooses contextually those accounting policies that aim either the decrease or the increase of its result. Dumitrescu (2013) shows that "as a norm, the accounting methods that lead to increased profits are preferred by firms with high leverage, by large companies that have a significant dividend policy and by companies in which the directors' remuneration is conditioned by the size of the result or where the administrators have little capital participation. An interesting point of view belongs to Bîgioi (2014) who believes that when tax legislation is not very clear, this can give rise to different interpretations of the companies, their tendency being to interpret the law in their interest.

The accounting methods that result in diminishing profit margins are generally preferred by enterprises under the direct control or influence of the state (operating in a strategic area or heavily subsidized or which have state capital), by large enterprises, to avoid political costs, as well as by

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

small and medium enterprises, with lower debt and a high rate of dividend distribution.”

An empirical study conducted by Vladu, A. B. & Groșanu, A. (2011) on how creative accounting is perceived in Romania by the regulators, Financial Auditors and professional bodies, found that the overstatement and understatement of profit and leasing are the main creative accounting techniques applied to the Romanian accounting environment. The respondents in the study mentioned consider that it is difficult to use creative accounting techniques and their detection process requires high professionalism. The respondents consider important the role of professional accounting and accounting regulation bodies to limit creative accounting practices. There are various methods used in order to corrupt the result.

Gabriels, X.&Van de Wiele (2005) investigated the level of ethical awareness, as well as the attitude towards creative accounting, among accounting and non-accounting students of the post Enron generation. The findings of the study refer to the fact that accounting students find creative accounting less acceptable than non-accounting students. The authors believe that a possible explanation is that accounting students through their education are more aware of the possible consequences of creative accounting for financial statement users. The difference does not only apply to students' attitude towards creative accounting, but also to more ethical orientation.

Another result of the study refers to the fact that there is not a significant difference in the ethical perception of creative accounting between men and woman. The researchers find that both accounting and non-accounting students tend to hold themselves responsible for creative accounting decisions in professional life.

In principle, people trust accounting figures, yet it is possible that, by breaking some of the accounting principles and rules, the accounting representation might provide a deceiving and distorted image of the economic reality of the enterprise. In other words, the behavior of the users of accounting information can be influenced by the distorted accounting image and, thus, the users might be manipulated. Just like in life, *for many times, the truth is beyond appearance...* these practices are made under the endorsement of the auditors who are called in to ensure the social reliability of the accounting information by certifying the fact that the financial statements reflect the economic reality due to their conformity with a certain referential. The results of an empirical study regarding auditors perception conducted by Balaciu et. al (2012) show that most of respondents (44%)

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

consider that financial statements prepared by companies are not transparent enough, 68% of them consider that accounting manipulation is a frequent procedure encountered in practice and 68% of the respondents believe that the stakeholders' interests can be affected by using creative accounting; 72 % of the investigated auditors consider that a consolidated control can diminish the tendency to use creative accounting.

In accounting, all the organizations recognize the need for a code of conduct. Profound economic crises that mankind barely cross force us back to the fundamentals, the current world trying to discover morally and spiritually. Growing virtues was a frequently debated issue since the ancient philosophers. According to Platon, virtue can be taught, if it is taught by a real teacher.

This is why he emphasizes the Socratic idea that doing injustice is, in all circumstances, a thousand times worse than suffering an injustice. Therefore, one who commits injustice, even if they are in possession of all power and riches, of reputation and all pleasures, is in all circumstances unfortunate and unhappy especially when escaping punishment for his actions, because he does not have the opportunity to move. Happy is only one who is in possession Justice and Goodness. Hence, we continue our efforts to bring into question the words of a disciple of his, Aristotle according to which, in terms of virtue, it is not enough to know the theory, but must try to possess and make use of it, or any other existing means to become a good man. Scribner (1989) describes the case of a consolidation approach to content on ethics in accounting courses. According to him, a weakness of the existing accounting courses is their failure to include the adequate exposure of ethical dimensions of accounting practice. Students will probably have a better chance to make ethical decisions when they have been less naive about the existence of ethical issues in practice and have been warned. MahdaviKhousi and Khotanlou (2012) support the idea of introducing a new approach to ethics education in the accounting profession by incorporating the Islamic ethics in all accounting education courses.

The solution proposed by Lehman (2014) is that professionals act as phronemos, without forgetting the ethical ambiguities in accounting and the critical role the syllabus / curriculum of accounting, education and pedagogy plays

Starting from the behaviour of the characters of the controversial biblical parable of the unjust steward, Balaciu and Bogdan (2012) carried out an exploratory research that bring into discussion the implications regarding

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

the compliance or non-compliance with ethical principles in the accounting profession.

Breban, Dumbravă & Crișan (2008, pp.18-19) believe that "ethics establishes principles of right and wrong by standards of conduct (professional), an attitude designed to facilitate the application of values by the existence of a Code of Ethics for almost any activity; in this regard there is the Hacker's code of ethics: "Information must be free"; the Cowboy's code of ethics: "Do not shoot first and do not hit the weak"; the Code of Ethics for galactic trade: "Committed to ensure the free alien market conditions".

In a study that present the perception of male and female accounting majors and non-accounting majors on ethics in accounting before and after Enron/Arthur Anderson scandals Onyebuchi (2011, p.76) shows that "all the accounting majors male and female, of the respondents indicated that the adoption of code of ethics would help organizational integrity. Among non-accounting, 67% indicated that the adoption of code of ethics would help organizational integrity, while 13% indicated that it would not".

Among the authors preoccupied with the necessity of morality and ethics in the field of accounting we can mention: LaGrone (1996), Armstrong at all (2003)

Locally, Feleagă & Malciu (2008), bringing into question a number of ways to analyze ethics and ways to combat creative accounting practices, believe that "although legal, creative accounting is considered ethically dubious". An argument in favour of ethical regulations is, according to Țurlea et all (2011), the need to legitimize the profession (macro level) and maintain the professional's reputation (micro level).

Currently, humankind lives within an interactive social system based on «being the first», «being more successful» encouraging the old-fashioned corruption and unfair behaviours when, actually, in a truly enlightened society, the purpose would be everybody's survival, a better life for everybody, the secret being transparency, as it has already said: «Know the truth and the truth will set you free.» (Walsch, 2003), because in such a society nobody would want to get anything on someone else's expense. Instead, the governments, the politicians, the world corporations do not want to allow the promotion of such an economic-social system, taking into account that the law of gain and the law for power are promoted. We are invited to remain open in order to live the experience of a new system of thinking within a society based on the principle of transparency, without being afraid that someone might have something to lose. Our contemporary thinkers agree that the new model of economic-social development will depend on a re-

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

newal of minds, mentalities, and of human beliefs, by directing human will towards the reception of the source of superior Consciousness, generator of unconditioned love, freedom of expression, creativity, inspiration and intuition that human mind can transform into material, concrete experiences and manifestations, for everybody's welfare.

We intend that, by this study, to expand the scope of investigation regarding the field of creative accounting. We will analyze the perception of the Romanian students from Accounting specializations in Romania regarding the manifestation of creative accounting phenomenon in the current context that the accounting Romanian system Romanian goes through on its harmonization with the European accounting referential and IFRS.

Methodology of the research

Our research regarding the students' perception on the accounting practices is a descriptive one of transversal type, we have used as an instrument of research the questionnaire. Our survey was carried out between May-July 2014. Our sample consists of accounting master students' in three of the Romanian representative universities.

The objectives of our research are: to determine the perception of the master students from 3 major Universities in Romania regarding the existence and forms of manifestation of the creative accounting phenomenon. We will use a descriptive analysis of the answers provided by the sample subjects and also a test of some research hypotheses. Synthetically, these are:

H1: The students' propensity towards risk is correlated with their accounting manipulation inclination.

H2: There is a correlation between the master students' tendency (as potential managers) to modify the accounting information and to distort the real image of financial reports and their ethical behavior.

H3: The master students' perception regarding the managers' interests are associated with their willing to help them modify financial reports.

The total population under analysis is represented by the 158 (the total number of students) master students the Academy of Economic Studies, București Faculty of Accounting and Management Information Systems (41%), master students from the Aurel Vlaicu University, Faculty of Economics Arad (29%), as well as master students at the University of Oradea, Faculty of Economics (30%).

Discussion

In order to analyse the answers given by the students, we built one-dimensional tables (based on a single variable) as well as crosstabulation tables, in which we presented the absolute and relative frequency of the answers, at the sample level. The survey contains two categories of questions: general questions, their role being to provide an as faithful as possible image regarding the personal profile of the students as well as questions regarding their perception on the existence and forms of manifestation of the creative accounting phenomenon within Romanian companies.

Descriptive analysis of answers

I. General questions

- a) The first general aspect which has been emphasised with the help of the survey questions is the *distribution of students according to gender*.

Table.1. Distribution of respondents in the sample of students according to gender

Answer choices	Simple absolute frequencies	Simple relative frequencies
Female	117	81.0
Male	27	19.0
Total	144	100.0%

Source: the authors, based on survey answers.

The results presented in *Table 1* show us that the majority of students answering the survey questions are women.

- b) Distribution according to age groups. Another variable characterising the sample of students from the demographical point of view is age.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

Table 2. Distribution of respondents in the sample of students according to age.

Answer choice	Simple absolute frequencies	Simple relative frequencies
18-25 years old	112	78%
26-35 years old	20	20%
Over 36 years old	12	12%
Total	144	100%

Source: the authors, based on survey answers.

One of the conclusions that can be reached after looking at *Table 2* is that most of students are aged between 18 and 25 years old, moreover 98% of the master students are under 35 years old.

c) We also wanted to emphasize the *distribution according to their professional history*. We have noticed that most of the master students (71%) had previously an accounting related job, 83% of them are currently employed, out of which 71% work in an accounting related job. A half of the students that are currently employed are satisfied with their wage.

II. Questions regarding the financial students' perception on the existence and the forms of manifestation of creative accounting phenomenon.

The most important part of our research has as purpose the determination of the students' perception regarding creative accounting techniques. We present here a part of the descriptive statistics referring to these aspects, and we will tackle the subject again and more thoroughly analyse them in the part dedicated to testing some research hypotheses.

The students in our sample were asked about their opinion about the phenomena that encourage the existence and the forms of manifestation of creative accounting. Most of the students (50% of them) believe that the accounting rules are the ones that are the main cause of the existence of creative accounting while 39% of the students from our sample believe that it is the managers' need of fiscal optimisation that generates creative accounting practices.

The bivaried analysis. Testing the research hypotheses

In this stage of our research we tried to validate the research hypotheses in our sample of students as well as to expand the results at the level of the total population. For this purpose, each hypothesis was analysed and inter-

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

preted, using for this specific statistic calculations, qualitative appreciations and direct observations of data gathered.

H1: The students' propensity towards risk is correlated with their accounting manipulation inclination.

Regarding the first hypothesis, we tried to investigate a possible correlation between the students' propensity towards risk and their accounting manipulation inclination. For the validation of this hypothesis we have analysed the answers to the following questions: II. 2. Would you buy a green card if you had a car? and a set of five questions regarding the willingness of the student to use creative accounting techniques. For these five questions we have determined an average score for each student, ranging from 1 to 5, the highest value indicating a maximum disponibility of the student to use creative accounting techniques. The distribution of answers at the sample level is the following:

Table 3. Distribution of answers to questions II.2 and average scores used in the validation of H1 research hypothesis

II.2. Average scores	Answers to question		
	Yes	No	Total
[1-3)	58	23	81
3	8	2	10
(3-5]	35	18	53
Total	101	43	144

Source: the authors, based on survey answers.

To analyse the existence of a correlation between students' propensity towards risk and their accounting manipulation inclination, we will use the χ^2 – Chi squared test, which is a non-parametric test, being applied both for numerical, quantitative variables as well as for qualitative characteristics, no matter their probability distribution. The Chi square value in our sample is 0,97, the value is slightly higher than 0, which indicates a weak correlation between the students' propensity towards risk and their accounting manipulation inclination. The value is not statistically significant as the critical value for 5% level of confidence and 2 degrees of freedom is 5,99, much higher than our calculated value. The H1 research hypothesis is therefore not validated.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

H2: There is a correlation between the master students' tendency (as potential managers) to modify the accounting information and to distort the real image of financial reports and their ethical behaviour.

The questions based on which we will test the validity of this research hypothesis are *II. 13. When taking a strategical managerial decision, are the ethics and deontology important?* And a set of five questions regarding the willingness of the student to use creative accounting techniques. For these five questions we have determined an average score for each student, ranging from 1 to 5, the highest value indicating a maximum disponibility of the student to use creative accounting techniques. We have constructed a crosstabulation between these values, which is presented in Table 4.

Table 4. Distribution of answers to questions II.13 and average scores used in the validation of H2 research hypothesis.

Answers to question II.13.	Average scores			Total
	[1-2,5]	[2,5-3,5]	[2,5-3,5]	
Strongly disagree	1	0	0	1
Disagree	2	2	6	10
Neither agree nor disagree	2	6	6	14
Agree	26	29	16	71
Strongly agree	29	17	2	48
Total	60	54	30	144

Source: the authors, based on survey answers

The Chi square value in our sample is 27,84, the value is much higher than 0, which indicates a strong correlation between the master students' tendency (as potential managers) to modify the accounting informations and to distort the real image of financial reports and their ethical behaviour. The value is statistically significant as the critical value for a 5% level of confidence and 8 degrees of freedom 15,5 lower than our calculated value. The H2 research hypothesis is validated.

H3: The master students' perception regarding the managers' interests are associated with their willing to help them modify financial reports.

The questions based on which we will test the validity of this research hypothesis are:

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

*II.8. The managers' concern when choosing their accounting policy is (...):
b) Maximising the financial result for a beautiful financial position and financial and economic output:*

c) Minimising the financial result for fiscal optimisation purposes.

II.9. If the manager asks you to, would you maximise the financial result in order for the firm to get a loan?

II.10. If the manager ask you to, would you minimise the financial result for fiscal optimisation purposes?

The students were asked to express their opinion regarding the managers concern, by choosing from a list of possible answers, ranging from “Strongly disagree” to “Strongly agree”. First we have associated values for each answer – 1 for “Strongly disagree” and 5 for “Strongly agree” and then we have determined an average score for each student. The higher the average score, the more open minded the students are regarding the managers' interest to use creative accounting techniques. We have also calculated an average score using the answers to questions II.9 and II.10, by associating the same scores for the answers as before.

The distribution of the scores at the sample level is the following:

Table 5. Distribution of the average scores used in the validation of H3 research hypothesis.

Answers to question II.9. and II.10	[1- 2,5)	[2,5- 3,5]	[2,5- 3,5]	Total
Average scores to question II.8				
[1-2,5)	1	1	0	2
[2,5-3,5]	16	17	17	50
[2,5-3,5]	23	28	41	92
Total	40	46	58	144

Source: the authors, based on survey answers

The Chi square value in our sample is 2,98, the value is higher than 0, which indicates a correlation between the students' perception regarding the managers' interests and their willing to help them modify financial reports. The value is not statistically significant at the critical value for 5% level of confidence and 4 degrees of freedom is 9,48, much higher than our calculated value.

The H3 research hypothesis is not validated.

Conclusions

Accounting helps managers in their efforts to improve the company's performance and its image but, unfortunately, some managers, exceeding their powers, seek a number of solutions without questioning the observance of ethical standards. Thus, they are tempted to ask the firm's accountants to use those creative accounting techniques that lead to them obtaining the desired result. The professional accountants will not have to let themselves influenced or constrained by them in the performance of their mission, but they have to comply with the International Code of Ethics for Professional Accountants developed by IFAC and the National Code of Ethics for Professional Accountants developed by CECCAR (The Body of Licensed Accountants and Expert Accountants in Romania). They will need to show, during their mission, integrity, honesty and professionalism. It is important that the manager of the company is a model of conduct within the firm, to model the behaviour of the employees, including the accountant, without requesting to use creative accounting practices that aim to "smooth the earnings", either the providing of a favourable image on it even if the existing gaps in the standards, their flexibility, the accounting choices and estimates are a number of factors that allow the expression of creative accounting techniques.

In the study reflected in our paper we started with three hypotheses but only one was validated. This hypothesis shows that there is a correlation between the master students' tendency (as potential managers) to modify the accounting information and to distort the real image of financial reports and their ethical behaviour. We explain this situation by the fact that the students had not enough information about ethics. This demonstrates that the information regarding ethics in the accounting field is poor in the Romanian economical education. We consider this situation must be improved because the students are not capable to make the difference between good accounting and bad accounting.

The obvious limitations of our study are mostly circumscribed around the determined sample and the research propositions. In our future researches we will try to extend our sample, including master students from abroad.

**Europe 2020 Strategy Implementation.
Grouping the Countries with the Application of
Natural Breaks Method**

JEL classification: *C00; E61; O52*

Keywords: *Europe 2020 strategy; multivariate analysis; zero unitarization method; natural breaks method*

Abstract: In the year 2015 the European Union reaches the five year period of Europe 2020 strategy implementation. Thus, the aim of the research is to group the European countries based on the level of fulfillment aims of the strategy with the application of natural breaks method. Special consideration was given to the results of New Member States of European Union. As a result in the first part of empirical research a ranking of EU countries with application of zero unitarization method for the year 2004, 2008 and 2013 was made. Based on the rankings the countries were grouped in five classes with natural breaks method. The analysis showed that in spite of economic difficulties in Europe after global financial crisis, from the year 2004 till the year 2013 New Member States had made an important progress in the implementation of Europe 2020 strategy.

Introduction

In the year 2015 the European Union has reached the halfway of implementation of Europe 2020 strategy, which should result in building the conditions for sustainable and inclusive economy delivering high levels of employment, productivity and social cohesion. The strategy is based on three mutually reinforcing priorities: a) Smart growth: developing an economy based on knowledge and innovation; b) Sustainable growth: promoting a more resource efficient, greener and more competitive economy; c) inclusive growth: fostering a high-employment economy delivering social and territorial cohesion (European Commission 2010, p. 3).

Europe 2020 is a continuation of the Lisbon Strategy. With its implementation Europe was aiming at “becoming the most competitive and dynamic economy in the world; based on knowledge, capable of sustainable economic growth with more and better jobs and greater social cohesion” (see. Royuela-Mora et al., 2005, p. 54-58; Lenain 2005, pp. 9-31). The Lisbon Strategy was adopted during the economic changes associated with development of the global knowledge-based economy (see. Balcerzak 2009, p. 3-22).

The aim of the paper is to analyze the fulfillment of the goals of Europe 2020 strategy from the perspective of the years 2004-2013 with special consideration to the progress obtained by ten New Member States.

The first year of the analysis is the year of the biggest European Union enlargement, which can be considered as the most significant institutional change in Central and Eastern Europe. In the same time it is the first year of the availability of the data for all the specific diagnostic variables for reaching targets of Europe 2020. The year 2013 is the last year when the data is available.

This article is a continuation of the research on the realization of Lisbon strategy made in the year 2008 (Balcerzak et al., 2008, pp. 77-88) and refers to the further research, which was aimed at evaluation of “starting position” of Poland in the context of Europe 2020 (Balcerzak 2011, pp. 31-41, Balcerzak 2015, pp. 343-352).

Method of dynamic taxonomic research

European Commission has proposed the following headline targets for Europe 2020 Strategy (Europe 2020..., 2010, p. 3; Balcerzak 2011, pp. 31-41):

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

- a) 75 % of the population aged 20-64 should be employed.
- b) 3% of the EU's GDP should be invested in R&D.
- c) The "20/20/20" climate/energy targets should be met (including an increase to 30% of emissions reduction if the conditions are right).
- d) The share of early school leavers should be under 10% and at least 40% of the younger generation should have a tertiary degree.
- e) 20 million less people should be at risk of poverty.

The problem of fulfillment these aims should be considered as a complex phenomenon. As a result, in order to evaluate the progress of European Union member states a classic taxonomic approach for organizing and sharing of objects was applied based on normalization of variables with zero unitarisation method (Kukuła 2000, pp. 7-16; Kukuła, Bogocz 2014, pp. 5-13). In the research a constant reference point for the years 2004-2013 was used¹.

The method allows to create rankings of countries. Based on the method it is possible to group the countries into five classes: a) countries with very high level of synthetic measure of fulfillment aims of the strategy; b) countries with a high position; c) the countries with an average position; d) countries with low position; e) countries with very low position in the sphere of reaching the targets of Europe 2020 strategy. For this purpose the method of natural breaks (Jenks optimization method) was applied. The idea of natural breaks method consists of minimization of variance for objects from the chosen subsets and maximization of variance between the subsets (Jenks, 1967, pp. 186-190). The division of object into subsets gives the possibility for obtaining relatively homogeneous classes of objects in terms of the level of development of the analyzed phenomenon (see Balcerzak, Pietrzak 2014a, 2014b). The grouping procedure was applied for three years: 2004, 2004 and 2013.

In the research the data form Eurostat was used (Europstat, Europe 2020 indicators, <http://ec.europa.eu/eurostat/data/database>, 15.03.2015).

The fulfillment of headline targets is monitored with the following specific diagnostic criteria:

¹ The research for Europe 2020 and Lisbon Strategy with changeable reference points for different years can be found in the following papers: Balcerzak et al., (2008, pp. 77-88, 2011, pp. 31-41; 2015, pp. 343-352), Olczyk (2014, pp. 21-43), Baležentis (et al. 2011, pp. 6-21).

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

Target 1. 75 % of the population aged 20-64 should be employed

x_{1t} – Employment rate of females – age group 20-64 (% of the population);

x_{2t} – Employment rate of males – age group 20-64 (% of the population);

Target 2. 3% of the EU's GDP should be invested in R&D.

x_{3t} – Gross domestic expenditure on R&D (% of GDP)

Target 3. The "20/20/20" climate/energy targets should be met (including an increase to 30% of emissions reduction if the conditions are right)

x_{4t} – Greenhouse gas emissions, base year 1990;

x_{5t} – Share of renewable energy in gross final energy consumption;

x_{6t} – Intensity of energy consumption estimated final energy consumption in millions tons of oil equivalent in relations to GDP;

Target 4. The share of early school leavers should be under 10% and at least 40% of the younger generation should have a tertiary degree

x_{7t} – Early leavers from education and training – females – % of the population aged 18-24 with at most lower secondary education and not in further education or training;

x_{8t} – Early leavers from education and training – males – % of the population aged 18-24 with at most lower secondary education and not in further education or training;

x_{9t} – Tertiary educational attainment – females – age group 30-34;

x_{10t} – Tertiary educational attainment – males – age group 30-34;

Target 5. 20 million less people should be at risk of poverty

x_{11t} – People at risk of poverty or social exclusion – percentage of total population;

x_{12t} – People living in households with very low work intensity – percentage of total population;

x_{13t} – People at risk of poverty after social transfers – percentage of total population;

x_{14t} – Severely materially deprived people – percentage of total population;

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

Among the diagnostic variable one can find both benefit ($x_{1b}, x_{2b}, x_{3b}, x_{5b}, x_{9b}, x_{10b}$), and negative variables ($x_{4b}, x_{6b}, x_{7b}, x_{8b}, x_{11b}, x_{12b}, x_{13b}, x_{14b}$). The stimulants were normalized with the formula 1 and the destimulants with the formula 2.

$$z_{ijt} = \frac{x_{ijt} - \min_{it} \{x_{ijt}\}}{\max_{it} \{x_{ijt}\} - \min_{it} \{x_{ijt}\}} \quad (1)$$

$$(i = 1, 2 \dots n); (j = 1, 2 \dots m); (t = 1, 2 \dots l), z_{ij} \in [0, 1]$$

$$z_{ijt} = \frac{\max_{it} \{x_{ijt}\} - x_{ijt}}{\max_{it} \{x_{ijt}\} - \min_{it} \{x_{ijt}\}} \quad (2)$$

$$(i = 1, 2 \dots n); (j = 1, 2 \dots m), (t = 1, 2 \dots l), z_{ij} \in [0, 1]$$

Assessment of the variable that characterizes the objects – a synthetic measure SM_{it} – was obtained with the formula 3.

$$SM_{it} = \frac{1}{m} \sum_{j=1}^m z_{ijt} \quad (3)$$

$$(i = 1, 2 \dots n); (j = 1, 2 \dots m); (t = 1, 2 \dots l); SM_i \in [0, 1]; z_{ij} \in [0, 1]$$

The result of the research is presented in table 1 and in figures 1 and 2.

Source: own estimation based on Eurostat data: <http://ec.europa.eu/eurostat/data/database> (15.03.2015).

Figure 2. The average level of fulfilment targets of Euro 2020 strategy in case of EU10 and EU15 in the years 2004, 2008, 2013

Source: own estimation based on Eurostat data: <http://ec.europa.eu/eurostat/data/database> (15.03.2015).

Figures 1 and 2 show significant heterogeneity between New and Old Member States in the beginning of the analysis. However, during the following years the NMS reached an important progress in reducing the gap to the Old Member States of the European Union. In 2004 the average value of synthetic measure for fulfillment the Europe 2020 targets for EU-10 was equal to almost 82% of the average value reached by EU-15. In the year 2013 this relation reached 92%. Also very good results of Baltic countries or Czech Republic with grouping in the same clusters with Old Members states, can be considered as significant success.

Conclusions

The analysis confirms existing diversity between Old EU members and NMS in the sphere of reaching all the targets of Europe 2020 strategy. However, the research also points that since 2004 till 2013 NMS achieved significant progress and managed to reduce the gap to EU15 by half. When one concentrates on the results of most important economies of Eurozone

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

the research shows rather moderate progress made by Germany and very weak results of Italy, which is analogous to the results obtained by these economies at the halfway of implementation of Lisbon strategy in the period 2000-2005 (Balcerzak et al. 2008, pp. 77-88). Taking into consideration the leading political and economic role of these economies, their lack of significant progress for almost last ten years shows the scale of structural problems of the EU.

Business Cycle Synchronization: A Regional Perspective

JEL Classification: *E32; E50; F44; R10*

Keywords: *business cycle synchronization; regional economics; optimum currency area theory; Hodrick-Prescott filter; European integration*

Abstract: Turmoil in euro area once more forces EU authorities to rethink future of further monetary integration. One of the most commonly used criteria for successful monetary in contemporary research is business cycle synchronization (BCS). Though BCS has been vastly described at country level, not as much attention has been put on the degree of BCS at regional level. Topic is important for 2 main reasons. The first is that determining degree of BCS at regional level can help in assessment of monetary policy effectiveness at country level, as well as giving point of reference for evaluation of perspective costs of participation in monetary union. The second is that there is theoretical dispute within the optimum currency areas literature between 'European Commission' and "Krugman" view that can be resolved a great deal through regional analysis. In order to assess BCS in EU Hodrick-Prescott, as well as Christiano and Fitzgerald filter to time series of real GDP for 24 countries, 82 NUTS 1, 242 NUTS 2 and 1264 NUTS 3 regions over the period of 1998-2010. Data was later used to create bilateral measures of BCS, which gave 276 observations on country level, 3321 on NUTS 1, 29161 on NUTS 2 and 798216 on NUTS 3 level. Results of the analysis support "European Commission" view and show very high degree of BCS within EU countries. Country level analysis also reveals that within the EU there exist groups of countries that could form effectively working monetary union based on BCS criterion.

Introduction

Turmoil in euro area once more forces EU authorities to rethink future of further monetary integration. One of the most commonly used criterions for successful monetary integration in contemporary research is business cycle synchronization (BCS). This paper tries to assess the degree of business cycle synchronization at regional NUTS 1, 2 and 3 level and for country pairs. This analysis allows to assess the extent to which each of the national central banks, as well as European Central Bank can conduct monetary policy effectively. The higher is the business cycle synchronization between two countries/regions the better it the ability of central bank to conduct common monetary policy for these two countries/regions.

This article proposes measure of business cycle synchronization base on correlation coefficient of deviations of cyclical component of real GDP from trend. Than measure is used to check what groups of countries can introduce common currency at relatively low cost. Same measures are used to check monetary policy effectiveness within countries.

Section 1 presents literature review, which is mostly concentrated around theory of optimum currency areas and business cycle synchronization at country and regional level. Section 2 presents data source and methodology used to construct the business cycle synchronization measure. Section 3 presents results and section 4 concludes.

Literature Review

The prospect of monetary unification in economics is usually considered in context of theory of optimum currency areas (OCA) based on seminal works of Mundell (1961), McKinnon (1963) and Kenen (1969). Nowadays 'New' theory of optimum currency areas (Tavlas, 1993) also considers more dynamic approach closely related to works of Krugman (1993) as well as Frankel and Rose (1998) and their *'The Endogeneity of the Optimum Currency Area Criteria'* hypothesis as well as Mundell (1973a, 1973b). Both international (Grubel, 1970; Mongelli, 2002 and 2008; Tavlas, 2008) and Polish (Nowak, Ryc, Żyżyński, 1999; Łon, 2007; Lis, 2008; Żyżyński 2009 and 2011; Osiatyński, 2011) economists have discussed potential benefits and costs of introducing common currency on the theoretical level. More complex measure of countries readiness to form a monetary union has been proposed by Bayoumi and Eichengreen (1997), who introduced unified index based on nominal exchange rate volatility,

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

trade intensity, trade similarity (intra-industry trade intensity) and differences in real GDP growth rate.

Empirical research in this area is very complicated due to problems with measurement of potential costs and benefits. For this reason researchers focus their attention on testing conclusions from OCA theory using two main approaches. In both cases authors try to find similarities in either economic shocks or business cycle – if there are strong monetary policy and externally flexible exchange rate are becoming very effective tool of common central bank.

The first one uses Structural Vector Auto Regression models (Blanchard, Quah, 1989; Taylor, 2004) for identification of economic shocks and was firstly utilized for OCA purposes by Bayoumi, Eichengreen, (1993). They examined demand shocks among European countries and US census regions, and found out that regions in US are characterized by higher degree of cohesion. Using similar approach Dumitru and Dumitru (2011) found significant role of idiosyncratic demand shocks among European countries, even some of the core countries. Beck and Janus using SVAR approach find low correlation of economic shocks among Euro Area countries (2013) and find high degree of synchronization of shocks for V4 countries (2014).

The second approach is concentrated on business cycle synchronization (BCS), and the literature on BCS has put high interest on parts of determinants. Using multi-equation approach Imbs (2004) find evidence for trade, inter-industry trade, structural similarity and financial integration are positively influencing BCS using data on Developed countries and states in USA. He also finds evidence for Endogeneity: direct and indirect of trade and financial linkages on business cycles synchronization. Results have been later reproduced on sample of European countries by Siedschlag (2010), as well as Déés and Zorell (2011). Kalemli-Ozcan, Papaioannou and Peydro (2009), in contrast with Imbs, find that financial integration influence business cycles synchronization negatively using single equation approach. They argue that cross-section analysis suggests positive impact of financial integration on business cycles synchronization, but panel approach reveals opposite effect. Beck (2013) using multi-equation approach intermediate effects of GDP per capita distance through structural similarity on business cycle synchronization and Chang, Kim, Tomljanovich and Ying (2013) impact of similarities in ruling parties.

Complex analysis with sensitivity checks (Leamer and Leonard, 1981; Leamer 1983, 1985; Levine and Renelt, 1992; Sala-I-Martin, 1997a, 1997b)

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

has been performed for BSC by Baxter and Kouparitsas (2004). They employ extreme bounds analysis to several potential determinants of business cycles synchronization, but beside the gravity variables they found only trade significant. In more recent approach Bower and Guillemineau (2006) using the same methodology but focusing their attention on the Euro Area, found only trade, economic specialization at industry level, fiscal deficits, price competitiveness and stock market differentials to be significant business cycles synchronization determinants. In yet another attempt to use extreme bound analysis Sachs and Schleer (2013) obtained significant results for institutional similarities and directions of structural reforms, but find trade, structural similarities and fiscal and monetary policy similarities insignificant in many of their specifications. Beck (2013) using Sala-I-Martin version of extreme bound analysis found robust impact of structural similarities and GDP *per capita* distance on BSC.

Gogas (2011) using one equation approach find positive effects of introducing common currency on BSC using sample of twelve European countries. On the other hand, Bordo and Helbling (2010) argue that increasing business cycles synchronization is a worldwide phenomenon. Lehwald (2012) using Bayesian dynamic factor model, argues that great part of increased business cycles synchronization among Euro Area countries comes from worldwide tendencies rather than ongoing integration.

All research mentioned above was taking into consideration only countries as a unit of measurement. As noticed by Alesina and Barro (2002), number of countries in the world is changing, but does not necessarily mean that the number of OCAs is changing with them. So country perspective instantly eliminates the possibility of OCAs being within countries or amongst parts of countries. In order to assess that lower level of aggregation is required – regional perspective. For these reasons this paper tries to concentrate on regional business cycles synchronization which did not have as much attention in the literature.

Artis, Dreger and Kholodilin (2009) find no evidence on convergence of regional business cycles for European regions and for USA, and claim that BSC have been stable over 1982-2007. Correia, and Gouveia (2013) examined business cycle synchronization in Portuguese regions between 1988-2010 and concluded that it has decreased over the period. Anagnostou, Panteladis and Tsiapa (2012) in comprehensive research find for 14 European countries differences in regional BSC that could be explain by trade and differences in the level of development. Marino (2013) on the sample from 12 European countries found that changes in regional business cycle

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

synchronization could be explained by distance and differences in economic structure.

Data and measurement

In investigation only European countries with data available on regional level were taken into considerations. List of all the countries and number of different NUTS 1,2,3 regions along with the number of possible pairs is available in table 1.

Table 1. Data description

For countries quarterly data about nominal GDP and price level (2005=100) from the first quarter of 1998 to the first quarter of 2014 obtained from Eurostat was used. Data was seasonally adjusted with X-13 ARIMA. For regions (NUTS 1,2,3) annual data about nominal gross value added (GVA) and price level was collected. Due to lack of data about the prices at regional level data for national price level has been used as a deflator. This is a common practice in regional research (example: Sachs, Sala-I-Martin, 1991). GVA data comes from Cambridge Econometrics and for the price level from Penn World Table 8.0, both cover 1991-2010 period. For comparisons between countries and regions data for 1998-2010 has been used. Longer periods have been used in order to get better results from Hodrick-Prescott filter. For the same reason quarterly data was used for GDP and prices and national level.

To justify usage of detrending methods tests for the presence of unit root has been used. Since Nelson and Plosser (1982) there has been substantial disagreement over the nature of the GDP trend (Rudebusch, 1993) – whether it is deterministic or stochastic. Due to that fact ADF (Said, Dickey, 1984) test was performed with two variations of the following equation¹:

¹ Case with no drift is not considered due to increasing nature of real GDP

$$\Delta Y_t = \alpha + \beta t + \delta Y_{t-1} + \sum_{i=1}^p \gamma_i \Delta Y_{t-i} + \varepsilon_t \quad (1)$$

where ΔY_t denotes change in real GDP, α is a constant term (drift), βt is a deterministic trend, δ is coefficient on lagged real GDP and γ_i is coefficient on i th lag of change in real GDP and ε_t is a residual term. Number of lags has been chosen with Schwarz information criterion. In the first specification deterministic trend is ignored, but included in the second. Diebold and Senhadji (1996) shown that whether these test detect presence of deterministic or stochastic trend depends on analyzed time period – the longer the higher the chance of encountering deterministic trend. This implies that for used periods used in this paper the test is expected to be biased towards stochastic trend. Presence of the trend was also confirmed with KPSS (Kwiatkowski et al, 1992) test. Results for specification without deterministic trend for countries have been presented in table 2. Results for regions at NUTS 1 level are in the appendix. Due to too high number of observations (242 for NUTS 2 and 1260 for NUTS 3) results for lower levels are of dis-aggregation are not presented, but confirm presence of trend in the data.

ADF test detects presence of unit root in time series for all countries except Portugal and Spain – two geographical close countries that have experienced significant turmoil during recent crisis. According to KPSS test results unit root is present in cases of all countries. Results for the specification (1) are presented in table 3.

For specification (1) ADF test shows presence of unit root in time series for all countries. KPSS shows presence of unit root in all cases except for Germany. This result along with the analysis of p values in both specifications, gives strong support to deterministic trend only in instance of Germany, though evidence for stochastic trend can be found. Table 3 shows that deterministic trend is significant also for Bulgaria, Estonia, Greece, Poland, Romania and Slovakia. In most of the case result point to stochastic trend and drift. As mentioned above this result was expected because of not long enough time period. This result has consequences for measurement of business cycle component and final result. It points out to changes in trend underlying GDP. This difficulty is addressed and overcome later in the text.

For regions KPSS test find unit root for every region at NUTS 1 level. ADF test fails to find unit root at 5% level of confidence for 5 regions, namely: Brandenburg, Mecklenburg-Vorpommern, Sachsen, Sachsen-Anhalt (all Germany) and Alföld és Észak (Hungary). This results point to the presence of trend in analyzed data set, and allows proceeding with filtering.

In order to extract cyclical and trend component of real GDP time series high pass Hodrick-Prescott (HP) filter has been used. HP filter assumes

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

time series (y_t) can be divided into cycle component (c_t) the trend component (g_t):

$$y_t = c_t + g_t \quad \text{for } t = 1, 2, \dots, T. \quad (2)$$

The HP filter extracts trend component by solving following mathematical programming problem (Hodrick, Prescott, 1997):

Table 3. Results of unit root test: specification (1) (ADF H_0 : series has a unit root; KPSS H_0 : series is stationary)

Table presents p values for ADF test as well as for all variables.

*/**/** denotes 0.1/0.05/0.01 significance level for KPSS statistic

Source: own calculations.

$$\min_{\{g_t\}_{t=-1}^T} \left\{ \sum_{t=1}^T (y_t - g_t)^2 + \lambda \sum_{t=1}^T [(g_{t+1} - g_t) - (g_t - g_{t-1})]^2 \right\}. \quad (3)$$

In that context HP filter can be seen as a generalization of the exponential smoothing procedures used analyzed by Brown (1962). If c_t and the second differences of g_t are normally and independently distributed, HP filter is an optimal filter (Rawn, Uhlig, 2002). λ is a parameter penalizing for variability of the trend component and its value is given by:

$$\lambda = \frac{\sigma_c^2}{\sigma_{\Delta^2 g_t}^2}, \quad (4)$$

which is the ratio of variance in the cyclical component to variance of the second differences in the trend component. The higher the value of λ the smoother the trend component is becoming and becomes OLS estimate as λ approaches ∞ . The value has been set to 1600 for quarterly and for 100 to annual data, which are values recommended by the authors as well as commonly used in the most of business cycles literature (eg. Backus, Kehoe, 1992). Great advantage of Hodrick-Prescott filter is the fact that it directly corresponds to commonly used in the economic literature definition of business cycle as a: *movements about trend in gross national product* (Lucas, 1977).

Finally cyclical component c_t is divided by the trend component g_t to create time series of deviations of cyclical part of real GDP from trend part, or in other words deviations of cyclical GDP from the natural level:

$$dev_t = c_t / g_t. \quad (5)$$

This transformation deals with the problem of stochastic trend, cause cyclical component is scaled by trend component.

For each pair of countries/regions i and j for each level of aggregation separately the value of the correlation coefficient is calculated for data obtained with HP (hp_{ij}) filter. This measure takes values from -1 to 1, where 1 reflects perfect business cycle synchronization. Because BCS can be analyzed using at least two countries, unit used in this research is pairwise

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

oriented. Advantage of that approach is that number of observations (o) for a given number of countries/regions (n) is given by:

$$o = \frac{n(n-1)}{2}, \quad (6)$$

so for 24 countries gives 276, for 82 NUTS 1 gives 3321, for 242 NUTS 2 gives 29161, 1263 NUTS 3 gives 796953 observations. In case of NUTS 3 one can be sure that all asymptotical theorems work very well. The rest of the reasoning is based on values of these results.

Results

Descriptive statistics for values of hp measure for region pairs at NUTS 1, 2 and 3 are presented in table 4. The headers of columns with „IN” present results only for pairs of regions inside the countries (Polish region with Polish region, German with German, but not Polish with German).

Table 4. Descriptive statistics of hp for NUTS 1, 2 and 3 region pairs: all and within countries

Source: own calculation.

Degree of business cycle synchronization is very high at all three levels of aggregation though the highest is at NUTS 1 level (0.89). Average value of hp is decreasing with disaggregation, which is expected result. Nevertheless this very high value for all three levels of disaggregation indicate that

conduction of monetary policy would be on average rather effective judging from region perspective. On the other hand distribution in all cases is far from normal, which might indicate that there is some systematic factor attributing to skewness. For this reason statistics were calculated separately for pairs of regions within countries. Mean values within countries are significantly higher – by approximately 0,1 for NUTS 1 and NUTS 2 and 0,08 NUTS region pairs. Standard deviation for “inside” pairs is on the other hand significantly lower, approximately by factor of 12, 4 and 2.1 for NUTS 1, 2 and 3 region pairs respectively.

Figure 1. Kernel Densities for NUTS 1, 2 and 3 region pairs: all and within countries.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

Conclusions from table 4 are supported by comparison of the distribution between all pairs of regions and pairs within countries. Kernel densities for region pairs are presented in figure 1.

Distributions for all and inside pairs are not normal and I get more concentrated around mean with the level of aggregation, which can be attributed to the sample size changes. Distribution for “inside” pairs is more centered and covers only very high values of correlation coefficient. These results suggest that business cycle of regions inside countries are on average more synchronized than those of regions from different countries. This result contradicts “Krugman’s View” which states that elimination of barriers to all economic activities (ex. Trade, mobility of labor and capital) leads to higher degree of concentration of economic activity due to internal and external economies of scale. These in turn leads to higher specialization, fragility of regions exports to changes in demand and lower business cycles synchronization with other regions. Obtained result shows that regions are characterized by very high degree of business cycle synchronization, especially within countries. This also supports “European Commission View”. Further economic integration by eliminating barriers to economic activity and introducing similar policies – *ergo* making groups of countries more like one country – will lead to tighter business cycle synchronization and can make common monetary policy effective.

Table 5. Descriptive statistics of *hp* for pairs of countries and NUTS 3 level pairs within Poland, Germany, France and UK

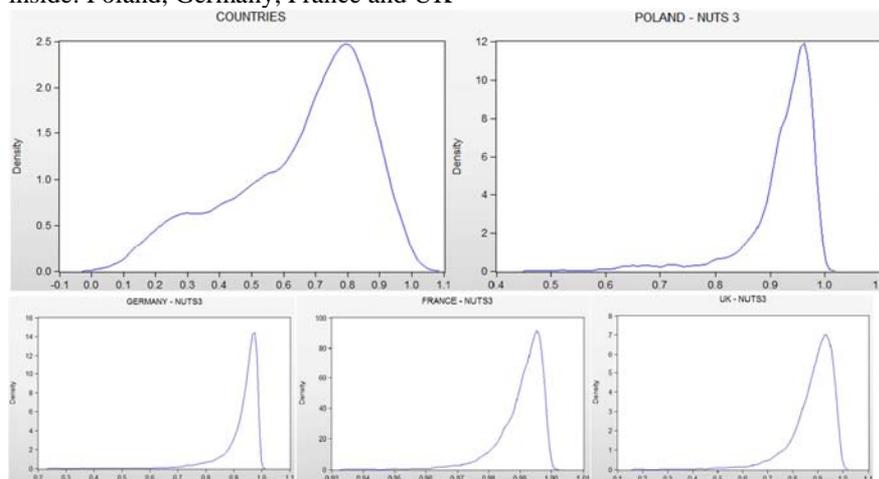

Statistic	COUNTRIES	POLAND	GERMANY	FRANCE	UK
Mean	0.65	0.92	0.93	0.99	0.88

Source: own calculation.

Results for regions are very different from pairs of countries, which are presented in table 5. Mean value of correlation coefficient for country pairs is equal 0.65, which is lower by 0.3 from NUTS 3 region pairs. Standard deviation is equal to 0.21, which in turn indicates lower concentration of the results. Distribution is not normal what can be seen from kernel densities in figure 2. Distribution almost entirely covers only values from 0 to 1. This suggests that in total business cycle synchronization among European countries is fairly strong, but degree differs significantly between pairs. The highest density of observations is around 0.75 what strengthens the point.

Table 5 also displays descriptive statistics for NUTS 3 region pairs inside Poland, Germany, France and UK. Result for these countries confirm that in all cases monetary policy can be implemented very effectively. This is especially true in case of France where mean value of *hp* measure is equal 0.99 with standard deviation equal to approximately 0.01 Degree of business cycle synchronization is also very high for Poland with mean of 0.92 and standard deviation of 0.07. Distribution in all cases is not normal, what can be seen in figure 2. Kernel distributions for regions inside countries are very concentrated and cover only very high values of correlation.

Figure 2. Kernel Densities for country pairs and pairs of regions at NUTS 3 level inside: Poland, Germany, France and UK

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

Results of the detailed analysis are presented in tables 6 through 9. For each country possible partners for monetary union are arranged according to *hp* measure in a descending order. NUTS 1/2/3 denotes average value for region pairs inside this country at a different 1/2/3 level of aggregation, while mean denotes average value with all countries. If country has higher business cycle synchronization with some other country than with other country than between regions inside it, then this country is a good partner to form monetary union with. In other words monetary policy could be implemented in this two countries, as effectively as for regions of one country – costs of participation in monetary union do not apply. This criterion is extremely rigorous and has been met only in couple of cases.

Values of correlation coefficient for NUTS 1, 2 and 3 level region pairs is higher than with any other country in case of Belgium, Greece, Poland, Spain, Holland, Hungary, Sweden, UK, Romania, France, Austria, Czech, Denmark, Ireland, Portugal, Slovakia, Slovenia, Estonia and Lithuania. Bulgaria has *hp* value for NUTS 3 “inside” equal to 0.79, while with Lithuania 0.8, so this country is a suitable candidate for monetary union with Bulgaria. Germany has higher value of *hp* with Italy and France than for region pairs at NUTS 3 level of aggregation (0.93). Latvia is characterized by very low value of correlation coefficient for pairs of NUTS 3 regions within countries (0.75) in comparison with other countries. This indicates that from regional perspective monetary policy cannot be implemented very effectively (especially in comparison with other countries). Values of *hp* for Latvia with Estonia, Lithuania, Hungary, Czech Republic, UK, Spain, Finland, Slovenia, Denmark, Ireland (in descending order) are higher than for within country NUTS 3 level region pairs. This means that possible number of candidates for monetary union with Latvia is quite extensive. In case of Finland *hp* with France is higher than for inside regions at NUTS 3 level inside countries (0.92), and with Germany, Italy and Spain is higher for than for NUTS 1 level regions. This indicates 4 very good candidates to form monetary union with Finland.

Even though there are possible partners for monetary union in case of Bulgaria, Germany, Latvia and Finland none of them are conceding – there is not even one pair of countries that could form monetary union at virtually no loss in monetary policy effectiveness. But criterion used here was ex-

tremely rigorous, especially if one takes a closer look at values of *hp*, one can see that they are very high in many cases. Values of *hp* measure above 0.8 were denoted in bold.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

Chosen value of 0.8 is somehow arbitrary but expresses rather high degree of business cycle synchronization. Taking this value as a point of reference Poland do not find any suitable partners to form monetary Union with. The highest value of hp is observed with Belgium and its equal to 0.77. Similar situation can be seen in instance of Greece, which have the worst results among all examined countries. In other words Greek business cycle is very poorly synchronized with cycles all of analyzed countries – monetary policy that is optimal for any of these countries would be inappropriate for Greece.

Using 0.8 as references value some countries have rather big number of possible candidates for introduction of a common currency: Belgium (9 countries), Finland (14), Germany (11), Spain (12), Holland (10), Italy (11), France (12), Austria (12), Denmark (15) and Slovenia (10). Numbers for other countries are not as big, but still many pairs of countries with highly synchronized business cycle can be found. This also indicates that a lot of countries from Euro Area form organism that can be considered quite close to optimum currency area. Germany, France, Italy, Austria, Belgium, Holland, Spain, Austria and Finland constitute such an entity – optimal monetary policy for one of these countries is very close to optimal policies for all others. Unfortunately same thing cannot be said about other members of Euro Area with Greece being a leading outlier.

Conclusions

Extraction of cyclical components with Hodrick-Prescott filter from real GDP time series in order to obtain correlation coefficient of deviations of cyclical component from trend resulted in obtaining 276 measures for country pairs, as well as 3321, 29191 and 796953 measures for NUTS 1, 2 and 3 level region pairs respectively. Analysis revealed that average value of hp measure for countries and NUTS 1, 2 and 3 regions are equal to 0.65, 0.89, 0.88 and 0.85 respectively. This shows that business cycle synchronization at regional level is generally higher than at country level, but is mostly driven by high degree of business cycle synchronization among regions within countries. This result contradicts “Krugman’s View” which states that elimination of barriers to all economic activities leads to higher degree of concentration of economic activity due to economies of scale. These in turn leads to higher specialization, fragility of regions exports to changes in demand and lower business cycles synchronization with other regions. To the contrary it gives support to “European Commission View”.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

Further economic integration by eliminating barriers to economic activity and introducing similar policies – *ergo* making groups of countries more like one country – will lead to tighter business cycle synchronization and can make common monetary policy effective.

Very restrictive criterion that used comparisons of business cycle synchronization at regional level within countries with country level correlations was used to access whether two countries can enter monetary union with each other with virtually no cost of monetary policy effectiveness loss. This restrictive criterion showed that 4 countries have candidates for effective monetary union formation, namely: Bulgaria, Finland, Germany and Latvia. On the other hand requirement must be fulfilled for two countries – and that criterion was not met. Using less restrictive criterion of correlation coefficient equal to 0.8 it turned out that a lot of countries have many good candidates to introduce common currency with. For example: Belgium (9 countries), Finland (14), Germany (11), Spain (12), Holland (10), Italy (11), France (12), Austria (12), Denmark (15) and Slovenia (10). Numbers for other countries are not as big, but still many pairs of countries with highly synchronized business cycle can be found. This also indicates that a lot of countries from Euro Area form organism that can be considered quite close to optimum currency area. Germany, France, Italy, Austria, Belgium, Holland, Spain, Austria and Finland constitute such an entity – optimal monetary policy for one of these countries is very close to optimal policies for all others. Unfortunately same thing cannot be said about other members of Euro Area with Greece being a leading outlier.

Results also show that Polish National Bank can use monetary policy very effectively, no matter what regional level of aggregation is used as reference point. On the other hand values of business cycle synchronization for Poland and other countries are very low. This indicates that there are no good candidates to form monetary union with Poland. Poland is also second outlier, after Greece, of the analyzed group. This result should not worry cause low degree of business cycle synchronization with other European countries can be attributed to well economic performance of Poland during recent crisis.

**Estimation of Export Specialization:
Lithuanian Case**

JEL Classification: *F1; F11; F14*

Keywords: *trade; export; export specialization; revealed comparative advantage index; trade dissimilarity index*

Abstract: This paper investigates the nature and pattern of export specialization in Lithuania. The aim of this paper is to estimate the nature and pattern of Lithuanian export specialization under existing conditions. Seeking to define the nature and pattern of export specialization, the basic methods of export specialization measurement and the nature and pattern of export specialization in trade between Lithuania and the EU are determined. For measurement the pattern of export specialization in Lithuania two approaches are adopted. The index of export specialization is used to determine the pattern of comparative advantage. Secondly, trade dissimilarity index is used to predict structural changes in Lithuanian exports. Using these methods of measurement and standard international trade classification (SITC) was determined the nature and pattern of Lithuanian export specialization. It was found that the biggest flows from Lithuania to the EU are in such groups: food, drink and tobacco; raw materials; mineral fuels, lubricants and related materials. These calculation results show the main directions of nature and pattern of export specialization. This research could be useful for preparing and forecasting the possibilities of Lithuanian export development.

Introduction

International trade practice shows that economic instability of countries and lack of trust for foreign trade partners are the main factors impeding the development of export. For various countries, exports are a major source of foreign exchange, a way to maximize economies of scale and specialization and a channel to new technologies and knowledge spillovers (Lall, 2000, pp.337-369). Specialization patterns and an increasing higher value added of county's exports have important implications for productivity and economic growth. A country's specialization pattern should reflect structural phenomena such as its factor endowments, economies of scale, relative gap of factor productivity, or specific advantages of firms and industries (Santos-Paulino, 2010, pp.1095-1116). Existing research shows that the variety of goods that a country produces and exports is affected by specialization, which in turn affects economic growth (Amable, 2000, pp. 413-431, Hausman et al, 2007, pp.3-42). Countries specialize by exploiting their comparative advantage arising from differences in technology, innovativeness and differences in factor endowments (Bernatonyte & Normantiene, 2009, pp.7-17). Classical approaches to international trade and specialization, such as D. Ricardo theory of comparative advantage and Hecksher-Ohlin theory of factor endowments state that countries with different resources or factor endowments will trade with each other (Husted, Melvin, 2013, pp.104-105). This traditional approach emphasizes the role of specialization in international trade which increases operating efficiency and thus totals productivity.

Many studies suggest that traditional sources of competitive advantage (e.g. natural resources, access to financial resources, economies of scale, etc.) no longer suffice, growing relevance has recently been attributed by researches to human resources and their management (Kazlauskaite & Buciuniene, 2008, pp.78-84). Recent empirical studies confirm the argument that in which products economies specialize and what they export matters for economic performance (Lewer et al., 2003, pp. 39-46). Today specialization is a dynamic process and its effect on productivity depends on the circumstances in which industries operate.

EU enlargement creates a wider single market, which stimulates structural adjustment and economic specialization. This implies an increasing interest in analyzing export specialization patterns within the EU market. Several studies have assessed the evolution of the export patterns in the transition economies (Bernatonyte & Normantiene, 2009, pp. 7-17).

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

Lithuania's integration to the European Union has opened huge possibilities for export development. It was determined that in recent years export of Lithuanian goods into EU countries and import from the EU comprised the biggest share of all export and import. Researches show that the economic crisis and Russian embargo have a significant influence on the changes of nature and pattern of Lithuanian export specialization. At the same time, researches investigating such changes are missing. For this reason the actual problem is to estimate the nature and pattern of Lithuanian export specialization under the changed conditions. In order to estimate the nature and pattern of export specialization it is necessary to analyze the problem of its measurement.

Methodology of the research

The research examines the nature and pattern of export specialization in Lithuania. In order to estimate the nature and pattern of Lithuanian export specialization, the methods of assessment of export specialization were examined and the best methods were selected on these grounds.

Researchers have employed a number of measures of export specialization. They are used for studying the structure and determinants of country's export and to identify the basis on which to build competitive advantages (Bernatonyte & Normantiene, 2009, pp.7-17). The concept of comparative advantage is widely used in modern economic literature to evaluate the patterns of trade and specialization of countries in commodities which have a competitive advantage (Saboniene, 2009, pp.49-57). The indicator of the revealed comparative advantage provides a more concise picture of export specialization. The concept of revealed comparative advantage was introduced by Liesner (1958), but refined and popularized by Bela Balassa and known as the 'Balassa index' (Balassa, 1966, pp. 114-121). It is widely used empirically to identify a country's weak and strong export sectors. Michael Porter uses it to identify strong sectoral clusters (Porter, 1990, pp.45-50). Balassa (1965) explored the possibility of relying on various theoretical explanations of international trade to determine the patterns of comparative advantage (Balassa, 1965, pp. 35-55). The revealed comparative advantage (RCA) index is defined by Balassa (B) (1965) as follows:

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

$$B_{ij} = (X_{ij} / X_i) / (X_{wj} / X_w), \quad (1)$$

Where: X_{ij} is country's i export of sector j ; X_i – total export of country i ; X_{wj} – world export of sector j ; X_w – total world export.

If the share of sector j in total exports of country j is higher than the equivalent share of sector j in world exports, then $B_{ij} > 1$ and country j is classified as having a revealed comparative advantage in sector j . A value of less than unity implies that the country has a revealed comparative disadvantage in the sector j . The Balassa index has been subject to several critiques, leading some authors to propose several modified versions. Laursen (1998) suggests a transformation that produces a symmetric outcome, ranging from -1 to 1 with a threshold of 0; Proudman and Redding (2000) suggest a transformation that results in a constant mean across the different sectors for a given country. As in the Proudman and Redding (2000) contribution, the product specialization index suggested here has a clear and well-defined link with the original Balassa index (Laursen, 1998, pp. 30-42); Prodman & Redding, 2000, pp. 373-396).

The export specialization index (ES) is a slightly modified RCA index, in which the dominator is usually measured by specific markets or partners. It provides product information on revealed specialization in the export sector of a country and is calculated as the ratio of the share of a product in a country's total exports to the share of this product in imports to specific markets or partners rather than its share in world exports:

$$ES = (X_{ij} / X_{it}) / (m_{kj} / M_{kt}), \quad (2)$$

Where X_{ij} is the value of country's i export of product j ; X_{it} – total export of country i ; m_{kj} – the value of import of product j in market k ; M_{kt} – total import in market k .

The ES is similar to the RCA in that that the value of the index less than unity indicates a comparative disadvantage and a value above unity represents specialization in this market (Trade indicators, 2010).

A common measure for export specialization in the literature is the herfindahl index on exports. The evolution of the herfindahl index of export specialization might reveal to what extent a given country is becoming more specialized or diversified, regardless of how the economic structures of other countries are evolving. A higher index indicates that the country exports in a smaller range of sectors and hence is more specialized (Trade

indicators, 2010). Santos-Paulino (2010) used the trade dissimilarity index to illustrate how specialization might affect a country's export productivity (Santos-Paulino, 2010, pp.1095-1116). Trade dissimilarity index reflects the adequacy of a country's trade pattern or specialization, that is, it considers the uncertainty in the real growth of exports. The indicator tries to predict structural changes in a country's exports. Also, it evaluates if a change in the behaviour of exports is oriented towards more dynamic products demanded by the rest of the world, or by the main trade partners of a country. It is calculated as follows:

$$A_j = \frac{1}{2} \sum_k \left| \frac{X_{jk}}{X_j} - \frac{X_k}{X} \right|, \quad (3)$$

Where k is the product and j is the country. X represents total exports.

Trade dissimilarity index ranges from zero to one, with higher values indicating higher dissimilarity. This indicator is higher when a country exports commodities in an industry with relatively low international demand. Lower dissimilarity index mean higher diversification and diversification into new export products protects economies against unstable price and terms of trade shocks. As indicated by empirical exercise in Amable (2000), a decrease in trade dissimilarity index has a potential positive impact on the trade pattern of growth (Amable, 2000, pp. 413-431).

Regarding to the fact that export specialization index helps assess a country's export potential, it will be used for used to analyse the nature and pattern of export specialization between Lithuania and the EU. The structural changes in Lithuanian export are examined using trade dissimilarity index.

Comparative analysis of export specialization in Lithuania

Development of Lithuanian economy depends on foreign trade to a great extent. Development of foreign trade encourages structural changes of economy, helps to make close economic contracts to businessmen of other countries and to adjust to market conditions better. Lithuanian integration into the EU opened huge possibilities for Lithuanian foreign trade. Regional integration oriented transformations in the Baltic region Formation of the unified social, economic and technological space in the Baltic region could be comprehend as a successful case of the regional integration oriented

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

transformations in the European Union (Melnikas, 2008, pp. 54-64). It was determined that in recent years export of Lithuanian goods into EU countries and import from the EU comprised the biggest share of all export and import. In 2014 export of Lithuanian goods to the EU comprised 54.9% and import from the EU –63.8 % (Statistical Yearbook of Lithuania, 2014). While demand in Eastern markets is shrinking, export conditions to EU countries are getting more attractive (Snieska, 2008, pp. 29-41). Increase of the share of export of industrial products in comparison to the general export to EU market shows possibilities for industrial production to compete in these markets.

The analysis of Lithuanian export specialization is based on export specialization index and trade dissimilarity index. Using export specialization index (ES) and standard international trade classification (SITC) are calculated the nature and pattern of export specialization in trade between Lithuania and the EU (Table 1).

The export specialization index presented in Table 1 indicates that in 2007-2013 Lithuania has achieved comparative advantage in trade with the EU in: food, drink and tobacco, raw materials, mineral fuels, lubricants and related materials and other manufactured goods.

Table 1. Export specialization indices of Lithuanian trade with the EU in 2007-2013

SITC	Year						
	2007	2008	2009	2010	2011	2012	2013
Food, drink and tobacco (SITC 0+1)	3.19	3.31	3.23	3.43	3.41	3.42	3.44
Raw materials (SITC 2+4)	1.94	2.02	1.99	2.01	2.02	2.14	2.16
Mineral fuels, lubricants and related materials (SITC 3)	2.62	2.64	2.60	2.62	2.67	2.69	2.70
Chemicals and related products (SITC 5)	0.84	0.83	0.85	0.86	0.88	0.89	0.89
Machinery and transport equipment (SITC 7)	0.53	0.55	0.54	0.55	0.65	0.67	0.69
Other manufactured goods (6+8)	1.13	1.16	1.16	1.18	1.19	1.23	1.26

Source: own calculations based on Eurostat (2014).

Data of Table 1 show that Lithuanian trading with the EU in food products, drinks and tobaccos during 2013 not only increased if compared to 2007 but also were the largest. Such situation was determined by many reasons, mainly, abolition of customs taxes for food products and alcoholic

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

drinks from the EU states. This reduced the prices of these products in 2005, increased consumption and import thereof. On the other hand, during the examined period from 2007 to 2013 export of the said goods increased.

Using the trade dissimilarity index standard international trade classification (SITC) are calculated the pattern of export specialization between the Lithuania and the EU (Table 2).

Empirical results indicate a large variation in the trade dissimilarity index (Table 2). Results presented in Table 2 reveal that the trade dissimilarity index is lower in 2008. This situation is connected with trade structure of Lithuania (i.e. trade structure of Lithuania is rather similar to the EU trade). The EU trade policy and implementation of its principles had influence to new members of EU export and import marketable structure. It should be noted that since the Lithuania becoming the member of the EU common custom tariff of the EU is valid in Lithuania. This means that the same customs are applied for goods which are imported to the territory of Lithuania from the third countries as importing goods to any other EU country. In order to make sure implementation of solid foreign trade policy Lithuania and other members of EU applies custom tariffs, quantitative limitations, tariff quotas and other means of foreign trade regulation to the third countries, which EU applies. Lithuania has applied other means of EU foreign trade regulation: antidumping, protective, compensatory, reciprocal means, quantitative limitations, non-tariff limitations (veterinary and other standards), and means, introduced as sanctions according to the decisions of the United Nations.

Table 2. Trade dissimilarity indices of Lithuania in 2007-2013

Year	Trade dissimilarity index
2007	0.34
2008	0.30
2009	0.31
2010	0.32
2011	0.33
2012	0.35
2013	0.36

Source: own calculations based on Eurostat (2015).

Thus, the analysis of export specialization reveals that after Lithuania becoming the member of the EU, having national economics under development, structural changes of its economy takes place. Having Lithuania trade with the EU in a free trade regime influences the increase in the volumes of im-

Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

port and export. A country can simultaneously decrease the amount of produced goods and to increase the range of goods useful to the consumers. Thus, the nature of international trade is changing as well as its structure of goods due to increasing specialization within a branch and the variety of produced goods increases.

Conclusions

The conducted analysis enabled to draw the following conclusions:

Firstly, research shows that Lithuanian integration into the EU has influence on changes of export specialization. It was determined that in recent years export of Lithuanian goods into EU countries and import from the EU comprised the biggest share of all export and import.

Secondly, in order to understand the nature and pattern of export specialization of Lithuania it were examined the methods of assessment of export specialization and on these grounds were selected the best method. The analysis of these methods shows that researchers have employed a number of measures of export specialization for studying the structure and determinants of country's export and to identify the basis on which to build competitive advantages. It was determined that that export specialization index is the best of measuring export specialization in trade between Lithuania and the EU. This index helps to estimate a sector in which the country is relatively more competitive in terms of trade.

Thirdly, on the basis of study many methods of export specialization were determined that the most appropriate method for measuring how specialization might affect a country's export productivity is trade dissimilarity index. Trade dissimilarity index reflects the adequacy of a country's trade pattern or specialization, that is, it considers the uncertainty in the real growth of exports. The indicator tries to predict structural changes in a country's exports.

Fourthly, on the basis of standard international trade classification (SITC) and export specialization index was determined the nature and pattern of export specialization in Lithuania. It is found that the biggest flows from Lithuania to the EU are in such groups: food, drink and tobacco; raw materials; mineral fuels, lubricants and related materials. Such situation was determined by many reasons, mainly, abolition of customs taxes for food products and alcoholic drinks from the EU states. This reduced the prices of these products in 2005, increased consumption and import thereof.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

On the other hand, during the examined period from 2007 to 2013 export of the said goods in Lithuania increased.

Fifth, on the basis of standard international trade classification (SITC) and the trade dissimilarity index are calculated the pattern of export specialization between Lithuania and the EU. It was determined the low level of trade dissimilarity index because trade structure of Lithuania is rather similar to the EU trade.

Thus the analysis of export specialization reveals that after Lithuania becoming the member of the EU, having national economics under development, structural changes of its economy takes place. Having Lithuania trade with the EU in a free trade regime influences the increase in the volumes of import and export. Lithuania can simultaneously decrease the amount of produced goods and to increase the range of goods useful to the consumers. Thus, the nature of international trade is changing as well as its structure of goods due to increasing specialization within a branch and the variety of produced goods.

Influence of Unemployment Benefit on the Duration of Registered Unemployment Spells

JEL Classification: *C01; C14; J64; J65*

Keywords: *Kaplan-Meier estimator; Cox hazard model; hazard ratio; unemployment*

Abstract: The purpose of the article is to present the analysis of the influence of the unemployment benefit on the duration of the registered unemployment spells. The authors made a hypothesis that the very fact of receiving the benefit prolongs the job seeking time and determines the intensity of unemployment leaving. The power of this influence varies depending on a subgroup the unemployed person belongs to. The study was conducted on the basis of data from the Poviast Labour Office in Sulęcın. The data were collected in the course of the European Union project implementation. The analysis covered two periods of time – before and after Poland’s accession to the European Union and the change in legal regulations concerning unemployment benefits. In each of the periods the authors observed separate cohorts of the unemployed registered in 2001 and 2005. The closing dates of the observations were: the end of 2003 and 2007, respectively. Also, the authors examined whether the EU projects implemented after 2004 had an effect on the length of the unemployment spells as well as on the intensity of finding a job.

Introduction

The influence of benefits, threshold salary and education on the unemployment duration is explained by the job search theory¹ which refers to certain principles followed by individuals in the process of job seeking. The job search theory represents a microeconomic approach. Its counterpart in the modern macroeconomic thought is a matching theory also called the search and matching theory². Nickell (1979), Hughes and Perlman (1984) have shown that the increase in unemployment benefits lead to prolonged spells of job seeking. The power of this interrelation is weakening as the unemployment spell is getting longer.

The purpose of this paper is to analyse the influence of the unemployment benefit on the duration of the registered unemployment spells. The study was conducted on the basis of data from the Poviát Labour Office in Sulęcín obtained under the European Union project³. The analysis covered two periods of time: before and after Poland's accession to the European Union and the change in terms of granting unemployment benefits (Act on promotion of employment and labour market institutions of 20 April 2004). In each of the periods the authors observed separate cohorts of the unemployed who had been registered in 2001 and 2005. The observation deadlines were the end of 2003 and 2007, respectively. In the paper the following hypotheses are made: the fact of receiving the benefit by an unemployed person prolongs their job seeking spell and affects the intensity of unemployment leaving; the implementation of the EU projects after 2004 has influenced the duration of unemployment spells. The effect of this influence varies among the sub-groups defined according to the categories of the job-seekers' attributes.

The job search theory explains why the unemployed individuals delay their employment decisions and extend their unemployment spell. The spells of frictional unemployment are the subject of the job search theory as

¹ The Nobel Prize winner of 1982 is regarded as the founder of the search theory.

² Noble Prize winners of 2001, Diamond, Mortensen and Pissarides contributed to the development of the search and matching theory and to its popularization in the job market analysis.

³ The project *The Analysis and Diagnosis of the Problem of Long-term Unemployment in the Poviát of Sulęcín (Analiza i diagnoza problemu długotrwałego bezrobocia w powiecie sulęcńskim)*, implemented as a part of the Operational Programme Human Capital 2007–2013.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

well as the search and matching theory, with both theories focusing on the demand issues. There are plenty of studies confirming the two theories.

Meyer (1990) investigated the impact of the amount and duration of the unemployment benefit on the duration of the unemployment spells. He was particularly interested in the analysis of events in the period before the termination of the unemployment benefit. He found out that higher benefits have a strong negative influence on the likelihood of unemployment leaving. This likelihood significantly rises towards the end of the period of benefit claiming. Meyer applied the methods for hazard function estimation and compared them with the methods that had been commonly used before, e.g. the Weibull model. He also discovered that the parametric approach gave more reliable estimations. The data came from the CWBH database and concern males from twelve US states observed in 1978-1983 (3365 observations). Their advantage was accurate information about the subjects' wages received in a week prior to unemployment and about the claimed benefits. The disadvantage was that the available information was restricted to the period of claimed benefits. The data concerning the unemployment period upon the benefit termination are considered to be censored. Meyer pointed to a high replacement rate amounting to 0.70 (the ratio of the average benefit to the average income earned before the unemployment spell). The presented empirical hazard defines the ratio of the number of unemployment exits over a given week to the number of the unemployed at the beginning of this week. High intensity is observed in the first few weeks, then between the 25th and 29th week, to be followed by the subsequent increase between the 35th and 38th week. Meyer attributes these intensity fluctuations to the period when benefit spells come to an end. His conclusions concerning the application of the model of proportional hazards include the finding that the 10% increase of unemployment benefits is associated with the 8.8% drop in the intensity of unemployment leaving. The obtained results refer solely to the period when the benefits are granted. According to Mortensen (1977), higher benefits may lead to stronger intensity in this period, while Katz (1986) claims that the intensity of unemployment leaving rises towards the end of benefit spells.

Han and Hausman (1990) conducted their study basing on the PSID database. It covered 1055 observations of breadwinners aged 20 to 65. The indicated a large number of unemployment exits in the 26th and 39th week (the moments when benefit spells come to an end in various American states). What is interesting, the intensity of unemployment leaving was strong also at the beginning of benefit spells. The authors divided the group

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

of the observed subjects into the ones who had found new employers and those who had returned to their previous employer. It turned out that job seekers who terminated their unemployment spells early were those who were re-hired by their former employer, even though they had been granted the unemployment benefits. In the case of the former group the unemployment leaving intensity does not increase until the end of their benefit spells.

Røed and Zhang (2003) did research into the effect of the benefit amount on the intensity of finding a job by people under 60 who had lost their full-time jobs in 1990 and did not qualify to be granted the unemployment benefit. The observation covered 103 thousand people. Those of them whose benefit spell ended and who did not find a new job were considered censored. Røed and Zhang proved that the benefit amount had a negative effect on the unemployment leaving intensity, especially in the case of the unemployed males. However, the threat of losing the benefit mobilised them (mainly women) to find a job. The researchers pointed out that the unemployment leaving intensity was rising by 60% (women) and 40% (men) at the end of their benefit spells. What is more, Røed and Zhang found out that the unemployment spells varied depending on the amount of the benefit: a 10% reduction shortened the job seeking time by 1 month in the case of men and by 1-2 weeks in the case of women.

This article is in line with the trend in the modern reference literature, which is the measurement of the unemployment benefit effects on the length of unemployment spells (Moffitt, 1985; Katz & Meyer, 1990; Hunt, 1995; Card & Levine, 2000; Hahn et al., 2001; Lalive, 2007). Unemployment brings negative effects to both the national economy and the well-being of households. This is why governments can and should use adequate tools to alleviate these effects, focusing in particular on the duration of unemployment. Unfortunately, there are no ready-made solutions to the problem. Both the unemployment rates and its mean duration vary from country to country, disregarding their development level. Governments offer diverse forms of support and activation programmes directed to the unemployed citizens in general as well as to their specific groups. The outcomes of individual programmes can be difficult to predict. Therefore, it seems essential to conduct studies on the effectiveness of these tools. One of the researchers dealing with this issue was Lalive (2007) whose interesting study focused on the possible effect of prolonging the unemployment benefit from 30 to as many as 209 weeks. Such an extended benefit was introduced by the Austrian government in 1988 and it was targeted at the 50+ unemployed who had been residents of the selected regions for at least

six months and who had been employed before. Obviously, such extension of the unemployment benefit resulted in the prolonged unemployment spells, especially in the case of women, which was due to the opportunity of early retirement. In the reference literature authors often point out that the maximum length of unemployment benefits is strongly correlated with structural unemployment (Nickell & Layard, 1999). The extended benefit time usually discourages the beneficiaries from job-seeking, thus leading to prolonged unemployment spells. For this reason, it is important to address support programmes to carefully selected groups of beneficiaries. In his research Lalive used the nonlinear regression model in its sharp form, with the thresholds of age eligibility and of distance to danger area border. Szmieder, von Wachter and Bender (2012) applied the nonlinear regression models with several age thresholds to study the effect of the potential benefit duration on the unemployment time throughout the whole economic cycle of 1980-2008 in Germany. The authors point out that they are basing their research on the model of job-seeking with limitations to liquidity and that the German system of unemployed benefits is ideal for this kind of studies. They adopt the age thresholds reflecting the potential benefit duration as the non-linearity thresholds (42, 44 and 49).

Methodology of the research

In this study the authors used the following methods to conduct the survival analysis: the Kaplan-Meier estimator (curves of surviving in unemployment, identification of hazards proportionality, the average time of unemployment spells, the intensity (hazard) of unemployment leaving) and the Cox model of non-proportional hazards (the relative intensity (relative hazard) of unemployment leaving). Kaplan and Meier (1958) proposed the way of estimating the survival function in the case of censored data:

$$\hat{S}(t_i) = \prod_{j=1}^i \left(1 - \frac{d_j}{n_j} \right), \text{ for } i = 1, \dots, k \quad (1)$$

where:

t_i – the moment when at least one event happened (deregistering),

d_i – the number of events in the time t_i ,

n_i – the number of units under observation in the time t_i .

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

The hazard (the intensity of deregistering from PLO) was estimated by means of the formula:

$$h_j = \frac{d_j}{n_j} \quad (2)$$

where:

d_j – the number of deregistered subjects in a given month,

n_j – the number of the unemployed subjects under observation at the beginning of that month.

The relative intensity of registered unemployment leaving was evaluated by means of the model of non-proportional hazards⁴ (following the recognition of the absence of non-proportionality on the basis of the course of the survival curves) in a form:

$$h(t, Z) = h_0(t) \exp(\beta Z + \delta Z \times g(t)) \quad (3)$$

where:

$$g(t) = \begin{cases} 0 & \text{for } t < t_0 \\ 1 & \text{for } t \geq t_0 \end{cases} \quad (4)$$

$$Z = \begin{cases} 0 & \text{no benefit} \\ 1 & \text{benefit} \end{cases} \quad (5)$$

In the model (3) the parameter β defines the influence of the endogenous variable on intensity, while the parameter δ indicates if this influence changes over time. The value $\exp(\beta)$ is understood as the relative intensity (hazard ratio) of leaving unemployment by the deregistered job seekers entitled to the unemployment benefit to the unemployment leaving by the job seekers deprived of this benefit due to their deregistration over the period of time shorter than t_0 . The value $\exp(\beta + \delta)$ is the relative intensity when the unemployment spell was longer than t_0 .

⁴ See more on the Cox non-proportional hazard model in (Bieszk-Stolorz & Markowicz, 2012, Bieszk-Stolorz, 2013).

The effect of unemployment benefit on the job seeking process – study results

In the study the authors used individual data of 2799 unemployed individuals registered in 2001 and 3377 ones registered in 2005 by the Poviát Labour Office in Sulęcín. The sizes of sub-groups can be found in Table 1. The individuals considered to be censored were those who remained registered by the end of the observation, i.e. who failed to leave unemployment.

For both the periods of observation the authors determined the Kaplan-Meyer estimators that were used to compare the probabilities of leaving the register by the individuals who were claiming the benefit and by those who did not, in total (Figure 1) and in the sub-groups. In the first months of unemployment we can clearly see the difference in the survival models constructed for the unemployment claimants and to those who were not granted the benefit. It means the absence of hazard proportionality in those groups. A similar shape of the survival curves could be seen in the sub-groups discriminated according to gender, age and education.

When analysing the results in Tables 2 and 3, we have come to the following conclusions:

- a) referring to the unemployed registered in 2001
 - 25% of the benefit claimants were de-registered after 5.6 months of job seeking, 50% – after 13.4 months, and 75% – after 21.5 months,
 - 25% of those who were not entitled to the benefit got de-registered after 3 months of job seeking, 50% – after 7.5%, and 75% after 18.9 months,
 - in the group of benefit claimants it was men who de-registered sooner, while in the group of the unemployed not entitled to the benefit women left the register earlier than men,
 - generally speaking, younger people were leaving unemployment more often,
 - unemployment spells got shorter with the rising level of education of the unemployed person.
- b) referring to the unemployed registered in 2005
 - generally speaking, the registered job seekers were leaving unemployment sooner than in the previous period of observation,
 - 25% of the benefit claimants got de-registered after 3 months of job seeking, 50% – after 6.9 months, while 75% – after 13.3 months,
 - 25% of those who were not entitled to the benefit got de-registered after 1.1 months of job seeking, 50% – after 2.8 months, and 75% – after 6.5 months,
 - in terms of gender, age and education the situation was similar.

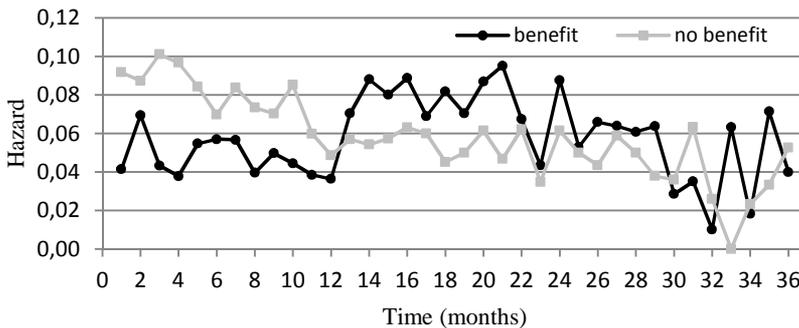

The mean values in Table 4 indicate the differences in the duration of unemployment spells. The unemployment spells were longer in the case of the benefit claimants in each of the sub-groups and in both observation periods. However, in 2005-2007 the average period of registration was shorter than in 2001-2003.

Figure 5. Hazard of the unemployment leaving in months (group 2005-2007) by gender

Source: own study based on the data from the Poviát Labour of Sulęcín.

The charts of hazards determined for benefit claimants and for the job seekers not entitled to benefits in both observation periods demonstrate the absence of proportionality (Figures 2 and 3). In the first 12 months we can see higher intensity of register leaving by the unemployed who were not entitled to the benefits than by the benefit claimants. In the 13th month the situation was reversed. A similar tendency took place in the gender, age and education sub-groups (see exemplary presentations of the age sub-groups in Figures 4 and 5). Therefore, in the Cox regression model (3) for the function (4) we adopted $t_0 = 13$. In the first period up to 13 months the values of hazard ratios were less than 1, which means that the intensity of the register leaving by the benefit claimants was lower than in the case of

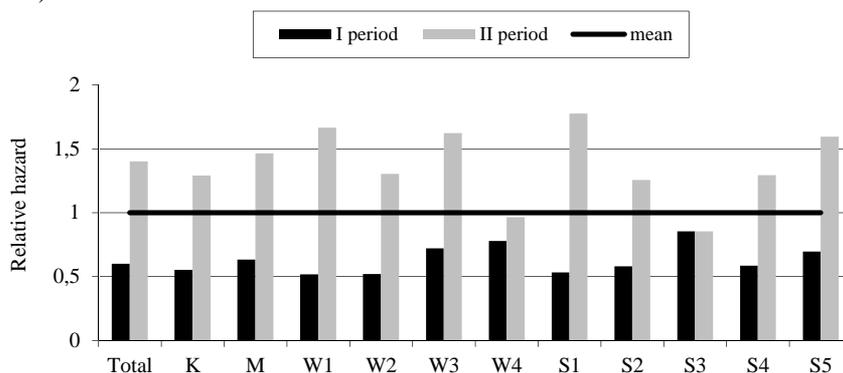

the remaining unemployed (Figures 6 and 7). When determining the hazard ratio, the peer group was the group average, which was marked in Figures 6 and 7 with a line in bold. After the 13th month (period II) the situation reversed in most of the sub-groups (excluding the insignificant ones). The parameter estimators together with errors and the significance level for the model in question are presented in Tables 5 and 6.

Figure 7. Relative hazard of the unemployment leaving in months (group 2005-2007)

Source: own study based on the data from the Poviát Labour of Sulęcín.

Conclusions

The study confirmed the research hypotheses. The fact of claiming the unemployment benefit prolonged the unemployment spells in both periods of observation. The loss of the right to the benefit increased the probability of de-registration in each sub-group. The fact of claiming the benefit reduced the likelihood of leaving the register in the first 13 months following

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

the registration in both 2001-2001 and 2005-2007. Poland's accession to the European Union and access to funding under projects implemented by the Poviats Labour Office in Sulęcín had an effect on reducing the registered unemployment spells and on the intensity of unemployment leaving. Since 2004 the PLO have implemented numerous projects financed by the EU⁵ and aiming at improving the situation of job seekers on the job market. The projects were directed at concrete groups of job seekers, e.g. those affected by long-term unemployment, young people, women or those who were planning to start their own business.

**R&D Tax Incentives in Industry: Empirical
Study Among Small and Medium Electronics
Manufacturing Enterprises***

JEL Classification: *E61 ; H29; D 92*

Keywords: *small & medium-size enterprises; R&D tax deductible; own research and development; Czech Republic*

Abstract: The paper deals with the topic of direct and indirect support for research and development and its use in small and medium-sized enterprises operating in the electronic industry. The Czech Republic is the geographic segment to be explored. A chapter on theoretical issues is followed by a description of the current situation in the Czech Republic and abroad and access to legal support for research and development in the business sector. Primary data collected from a survey are analysed in the analytical part. Some small and medium-sized enterprises of chosen group of manufacturing industry focus on research and development performed by their own means and they searched the possibility of financing the research from various sources. The initiative of these enterprises increase considerably their competitiveness in the global market and they realize the necessity of the innovation policy in the strategic management of the business, but still they do not make full use of all available supports in research and development from public sources

* The research is financed by Internal Grant Agency of the Brno University of Technology. Name of the Project: Economic Determinants of Competitiveness of Enterprises in Central and Eastern Europe. Project Registration No. FP-S-15-2825.

and instruments of fiscal policy, which allows the legislation of the Czech Republic.

Introduction

The third millennium, the change of regimes in the countries of Eastern and Central Europe, the expansion of the European Union (hereinafter the EU) has brought the enlargement of globalization and the pressure on sustainable development and growth of competitiveness of enterprises of all sizes. Companies can no longer operate only regionally, but if they want to succeed in the global market, they must be flexible when responding not only to the demands of consumers and customers, but all stakeholders, on the legislative changes and to the changes in the business environment. The turbulence that occurred to the EU when accepting new member states caused, thanks to the process of economic integration, the reduction of the technology gap between new and old members of the EU. This emphasized the dynamics of the export of the member countries. The link between technological innovation and the growth of the international competitiveness of both new and existing EU member states has been empirically confirmed. (Antimiani & Costantini, 2013, p. 355-389) One of the ways to succeed in the global market is therefore a systematic research, development and innovation of products and services provided, all in accordance with the protection of the environment. (Borghesi, 2015, p. 669-683) Innovation is not only the modern trend, but this is a basis for sustainable growth of enterprises, regardless of size. Product, process, marketing and organisational innovations must respond to the development and trends in the demographic area. (Bierwisch, Goluchowicz, & Som, 2014, p. 343-357).

The forces that drive innovations at the company level, and innovations that will succeed in improving the performance of the enterprise, are essential to establish the strategic objectives. Recently, there was a connection of the practical interest of the business community and the professional public as for the creativity and types of innovations in enterprises, in particular the impacts of the types of innovation activities on the performance of the business. The fact, how to successfully make use of the innovation in enterprises is very important in the time when innovation strategy is nearly the question of survival. This solution is not surprising, because the innovation could be described as a differentiation from the others, which will lead to an increase of the performance level and to a gain of a competitive ad-

Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

vantage. Evaluation of the types of innovation in organizations should help the managers to develop of production processes and productivity (Gelard & Emamisaleh, 2014, p. 222-228).

The impact to differences in the structural characteristics of the selected member countries of the EU were described in a study conducted in the private sector of manufacturing enterprises. (Mate-Sanchez-Val & Harris, 2014, p. 451-463) The business innovations were described using the two-step Heckman model. The European Community Innovation Surveys (CIS4) revealed that Spanish companies were at a different stage and they are behind with the UK companies. According to (European Commission, 2012) the Czech Republic is in the same category as Spain, it means the week innovators (moderate innovators) while the UK belongs among the innovators - followers. Similar recommendations such as for Spanish enterprises - to try to reach the technological level of innovators followers - should be recommended for Czech enterprises. Therefore, it is recommended to make use of public or regional support for the increasing market share of the enterprise.

Research activities and the following implementation of innovation belongs among the expensive budget items with no guarantee that the investment would have a real rate of return in the future for the company and the owner. Investment in research, development and innovations (hereinafter referred to R&D&I) should be a reasonable expenditure, a presumption for the continuous evaluation of innovative projects and processes. Ongoing evaluation of innovative projects should accompany the enterprises when deciding whether a project is beneficial for the company and whether it is appropriate to continue the innovation.

Definition

Several authors define the terminology and concepts dealing with innovation, research and development used in the literature. The concepts of innovation, innovation ability, development and applied research must be defined for the purposes of this contribution. Joseph Schumpeter mentions the importance of innovations for the competitiveness of the enterprise. He worked out the way of inherence in the productive process of capital, called it creative destruction and its effect is called innovation. The positions and importance of the business were introduced in 1911. The entrepreneur is, according to him, the only one who is innovating and developing unproven technologies (Jirásek, 2002).

**Proceedings of the 8th International Conference on Applied Economics

The main international source for the collection, analyse and use of information and data on the development and innovation is the Oslo manual. It summarizes the definitions and the legislations of the different EU countries. In the Czech Republic, the research is defined by the law 130/2002 Sb. as a systematic creative work of expanding knowledge, including knowledge of man or of society using methods enabling the confirmation, completion or overturn the previous results as basic and applied research. Development is then defined as the creative use of research knowledge to produce new or improved materials, products, equipment and services, including the acquisition and verification of prototypes. The result of research and development are, in many cases, innovations. The Oslo manual defines innovations in four types:

- Product innovation – means the introduction of new or significantly improved goods or services with respect to their characteristics or intended use. This includes significant improvements in technical specifications, components and materials, software, user friendliness or other function parameters.
- Process innovation – means the introduction of new or significantly improved production or supply methods. This includes significant changes in techniques, equipment and/or software.
- Marketing innovation – means the introduction of a new marketing method involving significant changes in product design or packaging, product placement, promotion of the product or of pricing. The distinguishing feature of a marketing innovation compared with other changes in the marketing tools of the company is the introduction of marketing methods, which were not previously used.
- Organization innovation – means the introduction of a new organisational method in business practices, the organization of the workplace or external relations. Organisation innovation in business practice includes the implementation of new methods for the organization of the standard practices and procedures for the implementation of the work (OECD - Eurostat, 2005).

This article examines the research, development and innovation in the field of electronic industry in the Czech Republic. The branch of electronic industry is one of the most important and significant part of the manufacturing industry and occupies a leading position in the Czech economy. It concentrates many groups and the total trade, capital and production consistency make electronic concerns the strong companies. These companies had to respond to globalization and entry of foreign investors. It is possible

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

to maintain continuity in business and achieve success only by developing innovative capabilities (Dul & Ceylan, 2014, p. 1254-1267).

The ability of competitiveness and sustainable growth are not possible at present without innovation capacity of enterprises. (Ebersberger & Herstad, 2013, p. 626-630); (Costa & Carvalho, 2013, p. 355-389) Small and medium - sized enterprises have due to the quick flow of information in the vertical direction and due to simpler administrative systems an advantage in pace of response to market demands and trends. Innovation can be interpreted as the ability to transform innovation inputs into outputs; it means the ability to transform innovation capacity and efforts to implement its results on the market. (Žižlavský, 2013, p. 234-250) Small and medium – sized enterprises have a position more difficult when financing R & D. Especially for this market segment the measures were taken in the form of direct support for R & D and deductible items (R & D Deductible) in 2005. The use of these types of aid is not frequent, as the following research reveals.

Methodology of the research

Respecting the identified objectives for basic research - to investigate the current state of the evaluation of innovative activities and sources of financing in the electronic industry enterprises in the Czech Republic were used scientific methods of work- secondary data analysis method. This method was used to obtain new knowledge about the quality and relevance. The source of secondary data was the literature, especially foreign literature - books, magazines, articles from scientific and professional conferences, published in the databases (Scopus, Science Direct, Web of Science, EBSCO). Questionnaires were used to obtain the primary data. The data obtained from the survey were enriched during structured interviews with owners or company managements. Logical methods were used for processing primary and secondary data. Analysis was used to study the records of interviews. Synthesis was the method used for data classification and processing of research results, induction was used for the generalization of all results gained in the survey. Statistical data processing was carried out in PC programme Statistica 12.

Before starting the research itself, the selection of respondents was done. The companies operating in NACE 26 and taking part in 2013 and 2014 at AMPER exposition were chosen to be analysed.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

Companies in this group of the manufacturing industry were focused on and they were chosen according to the participation in specific research "Effective economic management of the company with regard to the development of global markets" and "Microeconomic and macroeconomic principles and their effect on the behaviour of firms" and according the participation in the research on the financing of innovative activities through indirect support R & D.

Table 1. Numbers of enterprises surveyed according to the industry group.

Source: Own resources.

The intention was to contact enterprises based in the Czech Republic only. The Table 1 shows the number of respondents.

The investigation itself could be carried out under condition that the questionnaire would be simple, accurate and relatively short for a respondent. These conditions were an important criterion for the preparation of the questionnaire. The questionnaire was composed of four types of responses. There were questions with one or more optional answers. Questions aimed at measuring the innovations were pre-defined answers proposing the evaluation scale. Some questions were without predefined answers, free to be answered. In case of a company which does not implement any activity, the answer was redirected to the next block of questions.

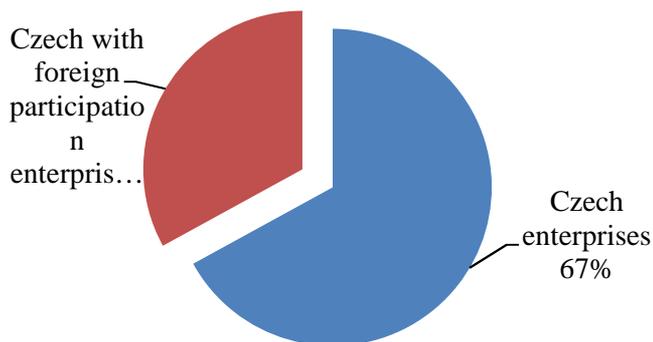

Research results

The questionnaire was divided in four sections:

- characteristics of the enterprise
- innovation activity
- sources of financing research and development
- evaluation of innovations for the enterprise

The questionnaires were distributed to companies, which I knew by name, so it was possible to add their economic data from the database or Amadeus Commercial register. The definition of micro, small and medium-sized enterprises used in the EU comes from Annex no. 1 of Commission Regulation (EC) No. 800/2008 of 6. 8. 2008, in accordance with Articles 87 and 88 of the EC Treaty declaring certain categories of aid are compatible with the common market (General Regulation of Block Exemptions). (Evropská společenství, 2006) Question N.1 and 2 were focused on the number of employees and the size of the turnover in 2013, possibly 2012. For simplification, the size of the company is based only on the number of employees. Micro and small enterprises prevail among the contacted companies, which are 63.9 %. That's mostly because the research was focused on companies based in the Czech Republic. The number of micro and small innovative companies was higher in a study conducted among manufacturing enterprises (Zizlavsky, 2013, p.234 – 251). Two-thirds of surveyed companies are owned by Czech owner, one third is a foreign-owned enterprise. These are mainly medium-sized enterprises.

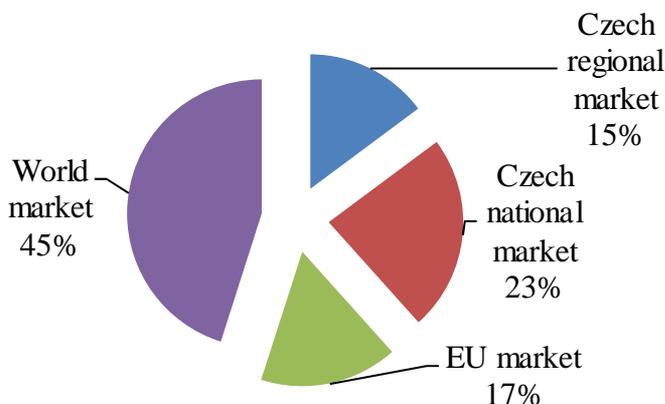

Graph 1. The ownership structure of companies

Source: Own research.

Surveyed enterprises answered the question about their regional influence. In terms of competitiveness, the presence in the global market is advantageous for the company. The deficit of customers can be compensated by the expansion of activities in another market. Territorial partition of companies is shown in graph 2. Companies focus the world market (45 %). Enterprises that not only exported to EU countries, but especially the Russian and American markets were represented in this category. Enterprises operating in the regional market were represented by 15 % and companies operating on the Czech national market were represented by 23 %.

Graph 2. Orientation to markets (%)

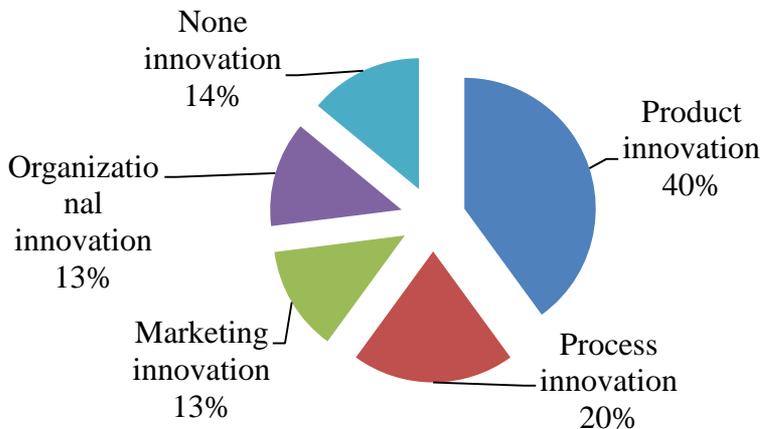

Source: Own research 2014

Further the respondents answered the question: what types of innovations were carried out in the company in 2011 – 2013. The information was used in the following questions relating to the evaluation of innovative means and funding R & D. The choice from 5 predefined answers corresponded to the classification according to the Oslo Manual (OECD - Eurostat, 2005). The most frequent type of innovations was the product innovation however, marketing and organization innovations were performed by the same percentage of companies. 14 % of companies only made no innovation. For more information see graph 3.

Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

Graph 3. Effected innovations (%)

Source: Own research 2014.

In the period following the economic recession and increasing pressure of globalization, it is expected that small and medium-sized enterprises are forced by the external conditions and the threat of competition to invest in innovations. On the other hand, the larger medium enterprises and large enterprises can increase operational efficiency and reduce costs by economies by quantity. The importance that the respondents see in various types of innovations is shown in table. 1

Table 1. Importance of individual types of innovations for companies

Type of innovation	Evaluation 1 - 5 (%)					Average	Modus	Standard deviation	Σ 1+2 (%)
	1	2	3	4	5				
Product innovation	53	27	13	0	7	1.8000	1	1.2540	80
Process innovation	23	52	9	0	17	2.3636	2	1.3093	74

Marketing innovation	23	23	23	8	23	2.8514	Multiple	1.4650	46

Source: Own research 2014

The results of weighted averages accentuate the importance of individual types of innovation for the business, product innovation are important for companies, but the innovation of new products may accompany the innovation process and marketing. The importance of innovations was evaluated in the scale: 1 - Very important, 2 - Important, 3 - Neutral, 4 - Not im-

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

portant, 5 – Completely unimportant. The table shows the percentage of positive responses, ie. the sum of responses 1 and 2. According to this summation of the respondents answer, the importance of innovation for the company is in the following order: product innovation, process, marketing and organizational innovation. Compared with research carried out throughout the manufacturing industry in the Czech Republic in the years 2010 - 2011 (Žižlavský, 2013, p.234 – 251) the difference is in ranking between marketing and organizational innovation. A higher percentage of enterprises in the electronic industry appreciate product innovation. Organizational innovations are according the percentage of answers less important for companies operating in electronic industry than for companies in manufacturing industry.

Other part of the questionnaire was to answer questions about the impetus for the introduction of innovations and to evaluate their significance for the company. Answers of respondents according to the level of importance in percentage and their statistical processing is shown in tab. 2.

Table 2. Effect of chosen innovative activities for companies

	Evaluation 1 – 5 (%)					Average	Modus	Standard deviation	Σ 1+2 (%)
	1	2	3	4	5				
Extending the assortment	69	23	8	0	0	1.3900	1	0.6339	92
Reducing material intensity of production	30	14	30	22	0	2.4583	Multiple	1.1600	44
The development of new technologies	31	45	8	8	8	2.1700	2	1.1896	76

Source: Own research 2014

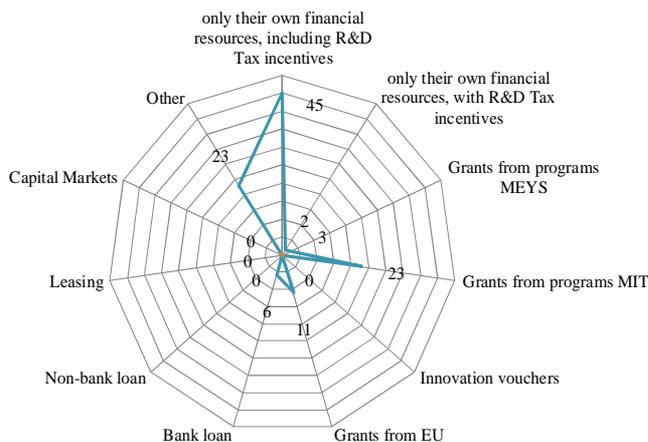

Extend the range of products and increase the quality of use of a product or provided services were the most significant impulses for the surveyed enterprises. R & D Council of the Czech Republic found that the Czech

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

production had relatively high expenditures of production, which is compared to the EU average of 28 countries 2.5 times higher to a production unit of GDP (R & D Council, 2014, p.3) and it is very alarming that to reduce energy and material costs of production is the least significant impetus for the introduction of innovations in the electronic industry. Similarly, the development of new forms of work organization, eventually organization of supplier relationships is considered “not very important” for enterprises. 44 % of respondents considered it “very important” or “important”.

The respondents provided information on sources of funding for innovation activities in the next part of the questionnaire. Small and medium-sized enterprises in the manufacturing industry often mentioned insufficient resources to cover R & D expenditures. (Nowakowska-Grunt, 2014, p. 789 - 795); (Kearney, 2014, p. 552 - 567) SMEs in the Czech electronic industry use mainly their own resources. The result of the survey is presented in the chart 1.

Chart 2. The sources of funding of research activities of SMEs in the electronic industry

Source: Own research.

The most common way of financing development activities of SMEs in the electronic industry are own resources. The enterprises use financing to their own detriment without the use of tax incentives. Tax incentives in the

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

Czech Republic were legitimized in 2005. Companies, as a legal entity, could make use of the tax allowances for research and development in the reporting period according to § 34 para. 4-8 of the Act no. 586/1992 Coll., On income taxes, and deductions among individuals according to § 34 para. 4 of the Act no. 586/1992 Coll. Among the respondents there were only two companies that took advantage of tax incentives for reimbursement of a part of eligible R & D costs. The company representatives said that the deductible item for R & D was the form less demanding as for administration as well as less time-consuming form of support from public funds than direct assistance in the form of grants. Tax incentives were used repeatedly. A quarter of companies used direct support for R & D programs of the Ministry of Industry and Trade (MIT). 13 % of companies only reported that in 2011 – 2013 they used funding support from the EU for research. Any of the companies had no experience with the use of innovation vouchers. This tool of innovation support was introduced in 2009 in the Czech Republic by the South Moravian Innovation Centre (hereinafter referred to as JIC). It is a way of collaboration between Brno research institutions and enterprises in the region. Vouchers are designed especially for small and medium-sized enterprises, which enable the company to fully concentrate on business, while the selected researcher will supply the knowledge necessary for innovation. The aim of the cooperation is to create high added value and increase the competitiveness of companies in the region. According to the authors of this idea the innovation vouchers help to eliminate mutual distrust between the academic and business backgrounds. (Jihomoravské inovační centrum) A total of 300 innovation vouchers for over 32 - million CZK were issued during the calls from 2009 to 2014. This principle of innovation support was also adopted by other regions, eg. Zlin, Liberec etc. Small and medium-sized enterprises of electronic industry do not benefit of leasing, non-bank loans and financing through capital markets for funding innovation activities.

The enterprises of the manufacturing industry felt that the most important factor limiting their innovating activities was a lack of funds and too high costs and risks of innovation in the years 2009 - 2011. (Žižlavský, 2013, p. 242) The companies reported in other responses the reasons for not using innovation vouchers, indirect support, subsidy programmes and bank loans to finance their research activities. More than half of the companies stated that they did not trust the system of allocation of funds for innovation vouchers and indirect support. At the same time, however, two thirds of respondents stated that management did not know about the possibility to

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

finance R & D expenditures through innovation vouchers and deductions when they were asked questions about this kind of financing.

The last part of the questionnaire asked questions about the ways of evaluation of innovation processes. The most important indicator for the evaluation of innovation activities for SMEs of electronic industry was *revenues*, which 27 % of companies considered “very important”. The evaluation of innovative activities through the Balance Scorecard, indicators of profitability and market potential was behind the revenues.

Conclusions

The survey was based on the interest of companies in practical experience in use of methods of funding research activities in the Czech industry. Based on experience with the use of direct aid and tax incentives in advanced European economies (Bozeman & Link, 1985, pp. 370 - 382); (Bozio, Delphine, & Loriane, 2013, p. 1-28); (Baghana & Mohnen, 2009, pp. 91-107); (Cappelen, Raknerud, & Rybalka, 2012, pp. 334-345); and evaluation of the legislation in the Czech economy (Elschner, Licht, Spengel, & Ernst, 2011, pp. 233-256), it might be assumed that the Czech production companies would invest in accordance with the International Strategy of competitiveness in the Czech Republic in research and development and constantly innovate. The survey revealed that the reality was different.

Real numbers of innovations, measurement of innovation activities in connection with the competitiveness of countries are measured by international indicators such as Innovation Scoreboard, GCI etc. Countries whose indicators are lower look for a way to increase innovations and enhance the innovation process. One of the means is to identify barriers. Identification of innovation barriers was effected in the Spanish manufacturing industry with 294 companies (Madrid-Guijarro, Garcia, & Van Auken, 2009, pp. 465-488). The biggest barrier is the high costs of the innovation process. This barrier affects more the small-sized enterprises than large enterprises. A less significant barrier to innovation is the discrepancy between employees and owners. Innovative activities of companies depend on the company's position in the region, the size of company and public support for innovation in the private sector. The identification of barriers was conducted from the perspective of managerial perceptions. *Internal barriers*: lack of financial resources, low-skilled human resources, weak financial position of a company, the high cost of innovations and investment risk of innova-

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

tions. *External barriers*: turbulence environment, lack of external partners for cooperation, lack of information, lack of public support. Similar results were reported by other authors (Cordeiro & Vieira, 2012, pp. 97-104); (Holmenlund, 2014); (Georghiou, Edler, Uyerra, & Yeow, 2014, pp. 1-12). In Finland, one of the most innovative and developed countries, the barriers of innovations are described to the smallest detail including recommendations on how to overcome these barriers. (Sandberg & Aarikka-Stenroos, 2014, pp. 1293-1305) Global European survey was performed in two stages and their results are presented by (Hölzl & Janger, 2013, pp. 1450-1468). They point to differences in barriers to the fast growing innovative companies and other enterprises in connection with the influence of public administration.

Identification of innovation barriers in countries with a similar historical development as the Czech Republic is based on a comparison of innovation barriers in different industrial branches. (Balcerowicz, Peckowski, & Wziątek-Kubiak, 2010, pp. 1-44) I did not find any detailed information in available resources about identification of innovation barriers in Hungary and Slovakia.

There are more authors in the local literature who deal with the issue of identification of innovation barriers, especially (Nečadová & Scholleová, Motives and barriers of Innovation Behaviour of companies, 2011); (Nečadová & Breňová, Inovační aktivity a konkurenceschopnost firem, 2012). They mention especially these kinds of innovation barriers:

1. high expenditures,
2. lack of specialists,
3. extremely long period of return on investment,

High expenditures and a long period of return on investment are the barriers of innovation activities that can be partially overcome by using direct and indirect support for research and development. Czech business sector has one of the best legislative support for tax incentives, ie the possibility to deduct incurred expenditures of research and development in the amount of 200 %. This possibility can be applied if the company is not profitable. Deductible item can be applied in three following tax years. There is existing legislative support for companies, therefore, SMEs finance the innovations mainly from their own sources and without the use of indirect support as the survey revealed. According to the survey the companies do not trust the subsidy programmes offered by MIT, MEYS and EU .

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

Small and medium-sized manufacturing companies in the electronic industry in the Czech Republic implemented all four types of innovations in 2010–2013, mostly product innovations. Owners and management of companies consider the impact of innovation on the position of enterprises as beneficial and companies behave responsibly when measuring the impact of innovations. Measurement of results of innovations using financial and non-financial indicators was not the main aim of this paper, but could be the subject of further survey in individual groups of manufacturing industry.

In conclusion it is necessary to add that funding of research, development and innovation in small and medium-sized enterprises of certain groups of the manufacturing industry is influenced by the position of SMEs in comparison with the big players in the market - access to information, sources of financing, own research departments, ensuring their own research by skilled human resources. Yet SMEs innovate, overcome in some researches defined barriers and increase the competitiveness of SMEs in the electronic industry, and therefore contribute to increasing the competitiveness of regions according to their competence and increase the chances of the Czech economy to progress to the category of *Innovation followers* eventually *Innovation leaders*. It is important to note that Czech SMEs should make better use of available resources of funding research and development in cooperation with research institutions, which can significantly reduce their own costs for R&D.

**Corporate Bankruptcy and Survival on
the Market: Lessons from Evolutionary
Economics**

JEL Classification: *G33*

Keywords: *corporate bankruptcy and survival; creative destruction; evolutionary economics*

Abstract: The following paper is a theoretical and empirical study. The terminological differences between bankruptcy and insolvency have been indicated and compared in the article. Most frequently considered aspects of bankruptcy appear in definitions. The first of them emphasises the economic character of bankruptcy. Insolvency is a culmination of a lack of financial means and the loss of solvency, which does not have a fading tendency but develops into a permanent phenomenon. In legal terms, solvency is an institution, whose purpose is to stop the accumulation of debts and most frequently it consists on the liquidation of the debtor's estate. A critical review of the scientific achievements of the representatives of evolutionary economics within the scope of bankruptcy and the survival of enterprises was presented. The analysed case of the Beta company, which went bankrupt, indicates that the companies which are not able to undertake proper adjustments to competitive conditions of the market at the right moment are eliminated from it. The theoretical law “the survival of the fittest” finds then its reflection in practice. The following research methods were used in the article: a descriptive analysis and the trajectories of J. Argenti in terms of models. Detailed examinations of files of insolvency proceedings of the Beta company have been carried out.

Introduction

Benjamin Franklin said that there were only two things certain in life: death and taxes. "Bankruptcy" and "insolvency" should be added to them (Cousins at al., 2000, p. 6). E. Mączyńska and Zawadzki (2006, pp. 21-24) point out that bankruptcies of enterprises are natural phenomena in the social market economy, ensuring necessary economic selection. However, they do not always facilitate a long-term increase of economic effectiveness. In relation to the increasing globalisation, a threat of the so-called insolvency chain (an insolvency domino effect) may be observed. According to A. Herman (2010) experiences arising from the last financial crisis in the global economy contribute to the awareness that insolvency and bankruptcy are an inherent feature of social market economies. According to F. Borman "Capitalism without bankruptcy is like Christianity without Hell." The market self-purifies itself from ineffective entities. Their resources may be utilised in a more effective manner by the more competitive entities. According to the theory of "creative destruction" by J. Schumpeter, the entities which are not adjusted or which are least adjusted are eliminated from the market. This raises many questions and doubts concerning the reasons of this phenomenon. But *scire est rerum cognoscere causas*. Many causes of bankruptcy, from strong market competition to tough luck, may be distinguished. Bankruptcy is a traumatic experience for many stakeholders, among others, owners, shareholders, employees and creditors. Bankruptcy contributes to the loss of: employment, savings, investments, movable and immovable assets. In the United Kingdom the loss of pension follows as well. As a result of insolvency the decrease of tax revenues and the destruction of regions also take place.

Herman (2010) points out that in contemporary market theory of enterprise there is still no developed bankrupt economics - such, which would demonstrate the processes and mechanisms of survival and insolvency of managing entities. There is a lack of one, consistent theory of bankruptcies and its elements are the part of separate economic theories. E. Mączyńska at al. (see 2010, pp. 5, 10) draws attention to the development of economics and bankruptcy economics.

The notions of bankruptcy and insolvency

Bankruptcy and insolvency are not identical terms. Insolvencies fulfil the function of necessary selection in business and they fulfil a significant function of rationalisation, purifying the market from the entities which cannot meet the requirements of effectiveness, which constitutes at the same time the element of the protection of creditors and other entities.

The notions of bankruptcy and insolvency are frequently treated as synonyms (Mączyńska, 2009, p. 57). It is not precise as bankruptcy is the notion of, first and foremost, economics, while insolvency is basically a legal category (*Bankructwa przedsiębiorstw...* 2009, p. 4). Identifying bankruptcy with insolvency is justified only in case of culpable bankruptcy, consisting on the penalty which is proportional to fault, which is regulated by specific provisions. Non-culpable insolvency is not regarded as bankruptcy in the economic terms as it does not arise from the irregularities in the management of an enterprise but from the external reasons, e.g. fraud of counterparty. The differences between bankruptcy and insolvency have been presented in table 1.

Table 1. The differences between bankruptcy and insolvency

Bankruptcy and insolvency Insolvency ≠ Bankruptcy		Insolvency = Bankruptcy	
Non-culpable		Culpable	
Is not subject to a penalty	Unintentional	Intentional	Intentional profit-driven
Is subject to a penalty			
Criminal liability of entrepreneurs (a fine, deprivation of the right to perform particular functions, a custodial sentence)			
Milder penalty	More acute penalty	The most acute penalty	

Source: Mączyńska (2009, p. 57).

From the point of view of economics, a bankrupt is an enterprise which is not able to settle its debts and the value of its assets is not sufficient to cover all liabilities (a bankrupt is also an enterprise which, in spite of the occurrence of the above-mentioned premises, still operates a business).

In legal terms insolvency of an enterprise occurs only after the declaration of bankruptcy by the court. Its purpose is to satisfy equally all creditors of a debtor, who is not able to satisfy each creditor separately. Bankruptcy should prevent carrying out enforcement against a debtor only by some

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

creditors (in the event the others don't have the enforcement title yet, e.g. when their claims have not been paid yet) and in case when there is a priority system in enforcement proceedings. This means that the fact of bankruptcy is established judicially on the basis of the request either from a debtor, or from some of creditors or a few creditors. In the first case it is voluntary bankruptcy and in the second one forced bankruptcy (Tokarski, 2013, p. 393-400). In economic terms, bankruptcy does not have to mean insolvency in legal terms, but each insolvency declared by the court means economic bankruptcy.

Methodology of the research

Research objectives

Scientific achievements of the representatives of evolutionary economics have been used to assess the adjustment of a selected enterprise to market requirements. The objective of the research was to recognise the mechanism of bankruptcy of a selected enterprise, whose object of economic activity was wholesale of food products, in the context of evolutionary economics. Among specific objectives the following have been indicated: the determination of the major reasons of bankruptcy as well as the presentation of bankruptcy trajectory of the purposely chosen young (around 5 years) food company Beta from Dolnośląskie Voivodeship.

The choice of the research object

The Beta enterprise, which declared bankruptcy, has been chosen for the purpose of research. The choice of the company was deliberate. A changed name of the enterprise was given in the paper due to business secret and data protection. The enterprise operated a business in a legal form of a limited liability company. Bankruptcy petition of a debtor was filed in the District Court in Wrocław. Relatively poor knowledge of the topic of bankruptcy of food enterprises supports the need to introduce research which may contribute to the better recognition of this phenomenon, including also the basic driving forces.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

Methods of data collection

Data concerning bankruptcy of the selected Beta enterprise come from the insolvency court files and from the financial statements of the company. A critical analysis of subject literature, national and foreign one, has been carried out.

Methods of data processing

Methods used in the paper:

- research case study,
- ratio analysis of financial statements,
- bankruptcy trajectory method of Argenti,
- examination of insolvency files.

The appearance and the development of crisis was presented by J. Argenti. He also distinguished three bankruptcy trajectories:

- 1) the bankruptcy trajectory of a newly established enterprise,
- 2) the bankruptcy trajectory of a young enterprise,
- 3) the bankruptcy trajectory of a mature enterprise (Argenti, 1976, p. 121).

Argenti distinguished four stages, which ultimately lead to bankruptcy:

- 1) problems in the operation of an enterprise start to arise, but they do not cause significant changes,
- 2) all irregularities deepen, mistakes are made,
- 3) significant irregularities concerning particularly the sphere of solvency appear,
- 4) the bankruptcy of an enterprise follows.

Method of presenting results

The obtained results have been presented in a descriptive and graphic form.

Bankruptcy macroeconomic outlook

Companies have been and continue to be the actual victims of the ongoing global financial crisis. Corporate bankruptcies in the eurozone were expected to increase by 21% in 2013 before ebbing back to a moderate growth rate of 7% in 2014. In Spain, it was expected a new all-time high

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

with nearly 11 000 companies defaulting 2014. A high number of bankruptcies influences on soaring unemployment and a real phenomenon of deindustrialization. After record figures in 2009, another flood of bankruptcies – from the United States to China to France – poured into sectors with tax incentives coming to a halt such as construction and services. The acceleration in the number of bankruptcies is more a result of market fundamentals: from slowdown in household consumption in Europe to sluggish exports for Asia. In Europe, the retailing, furnishing, automobile and consumer electronics sectors have been hit strongly. It is this industrial Darwinism, against a backdrop of ongoing credit rationing. The consequences are significant: in Asia, for example, companies are seeing their export markets decreasing and overcapacity is posing a problem (Subran, 2013, p.3).

The question arises if this economic turbulence (with the number of companies created also increasing in many countries) come to be synonymous with a renewal. According to the evolutionary theory of Schumpeter, such economic entropy could indeed foster a new beginning. The least adapted and, especially, the least innovative companies will give way to those that reinvent themselves and meet the needs of today. After the 2008 and the current chill in the economy, now Schumpeter's "perennial gale"; it starts to make a lot of sense. It is in sectors with high value added, intensive in talent, human capital and social capital, driven by research, innovation and entrepreneurship that these needs can be found. So the news may be bad, with soaring corporate insolvencies and heightening non-payment risk at a time when margins are already eroded. However, this could be a case of a step back in order to make a bigger leap forward. The condition for success is that adequate policy steps are taken in terms of innovation, business environment and incentives, especially to support startups, before it is too late (Subran 2013, p. 3).

Most frequently, bankruptcy precedes crisis, which is the effect of the impact of the adverse internal and external factors with a macroeconomic character. Among macroeconomic factors, the most influential one is the phase of the economic cycle, which includes a country and an economic growth rate. Unfavourable economic situation increases negative selection of ineffective entities, contributing to the change of resources allocation.

In many countries, there is a close correlation between the business cycle and bankruptcy figures. Generally, it takes GDP growth of 2% to 3% to stem the rise in bankruptcies, and there is a very high elasticity of bankruptcies to growth. A GDP growth reduction of 1 percentage point implies

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

a 5% to 10% increase in bankruptcies. In the second half of 2008, however, these general approximations, seen in practice from the start of the 1990s, were significantly exceeded: on top of the normal shock resulting from the economic cycle came the abrupt addition of exceptional factors directly stemming from the nature and impact of the global crisis. In 2009, it was in fact the record collapse in economic growth, due to the collapse in demand, that explains the bulk of the rise in bankruptcies, which proceeded with exceptional ferocity (*Corporate insolvencies...*, p. 4).

The Banque de France stressed in particular that the higher level of business creations during the 2003–2007 period – itself correlated with the business cycle – may explain the increase in the number of bankruptcies (Bruneau et al., 2012, pp. 119 – 220).

There is agreement in the financial economics literature regarding the existence of a link between bankruptcies and the business cycle. This topic has already been extensively investigated and it is acknowledged that some interaction exists. However, there is no agreement on the channels by which bankruptcies and the business cycle interact, nor on how to measure the link. Regarding the channels of interaction, the business cycle affects the environment of firms, and hence may explain, with a lag, the changes in bankruptcies over time, in addition to firm-specific variables like financial ratios. On the other hand, bankruptcies may affect the business cycle, marginally through lost capacities of production, and more significantly through credit rationing as shocks to credit supply have often been shown to be leading indicators of the business cycle. In addition, banks may limit credit supply because they become more risk averse when they observe more bankruptcies or because larger losses constrain their ability to expand assets. As far as measurement is concerned, the approaches followed in many studies are usually partial, as they focus on one-way interactions between bankruptcies and the business cycle (Bruneau et al., 2012, s. 220). (Bruneau et al., 2012, s. 220) attempted to merge two strands of the quantitative economic literature regarding how the macroeconomic environment affects financial fragility, and conversely how financial fragility affects the business cycle. It also considered evidence that points to two-way interactions between business bankruptcies and the macroeconomy.

Staszkiwicz (2013, p. 14) conducted correlation analysis on dynamic of GDP and company failure rate for Poland, Europe and USA for the period 2003-2011. It was found a negative correlation. An analysis was also undertaken for the relation between the rate of corporate failure in Poland and the rate of change of overall company's net turnover profitability. It was

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

observed no statistically significant correlation. An alternative significant variable was pointed out for a linear regression model. Staszkievicz (see 2013, p. 14) partly confirmed others authors' results.

Evolutionary economists on bankruptcies

The object of research, which is the economy, alters continuously. A. Hansen regarded this change as the first law of economics (Hansen, 1939, p. 1). Physiocracy, which developed in France over the period 1750-1780, finally losing ground to classical economics, which began to come from the United Kingdom, should be considered as the first economic theory in history. Physiocracy means the mastery over nature. Domination of the laws of nature over the laws of economics is the underlying law in this theory. The laws of nature are independent of the human will. They may and should be learned in order to be able to use them in a business activity. Later on this issue was ignored in economics (Bartkowiak, 2003, pp. 29-30, 33].

It was only after environmental limitations for a business activity started to become increasingly apparent (e.g. hurricane, drought, flood, etc.), that physiocracy started to return again. It found its particular reflection in the evolutionary economic theory of R. Nelson and S. Winter in 1982, belonging to Schumpeter's economic theory. For the researchers of evolutionary economics the needs to learn about the human motivations, a human decision-making processes, mechanisms of economic development and understanding of the activity of business entities become significant (Kwaśnicki, 1996, p. 2).

The terms "evolution" and "development" are often used interchangeably. The term "evolution" comes from Latin *evolutio* - unrolling (of a scroll); opening (of a book), *evolvere* - to unroll. The term "evolutionary economics" is currently used in many, sometimes very different, approaches to the analysis of economic processes. In the most general terms, it indicates the significance of economic and developmental changes, which is done in order to emphasise the opposition in relation to the economic analysis focused on the problems of balance and statistical models. In narrower terms, it refers to the metaphor based on the ideas of biological evolution taken from Darwin or Lamarck. Kwaśnicki (1996, pp. 3-4) says that nowadays a few detailed explorations of economic processes analysis characterised by the adjective "evolutionary" have crystallised:

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

- the economists, who perceive the economic process in a way proposed by Joseph Schumpeter, use the term “evolutionary economics” in order to underline the importance of economic changes in the long-term perspective, the role of innovation in the economic process and the approval of the role of an entrepreneur in the stimulation of a socio-economic development process. This approach is sometimes called Schumpeterian or Neo-Schumpeterian approach. The journal issued by the International Joseph A. Schumpeter Society is entitled *the Journal of Evolutionary Economics*. According to this approach, an evolutionary process is a dynamic and historical process, whose macroeconomic characteristics are the result of the behaviour of single business entities acting in microeconomic scale, whose characteristic feature is the diversity and heterogeneity of behaviours and two of its basic mechanisms are the search for innovation and the mechanism leading to the diversification of development and the selection process;
- the perception of the economic development of the Austrian School of economics is frequently defined as “evolutionary”, the work of Carl Menger, in particular his theory of the appearance of money and other social institutions, has a clear evolutionary character; frequent use of evolutionary analogies and metaphors by Friedrich von Hayek, especially in his later works referring to the concept of spontaneous development (e.g. *Fatal Conceit*) also allow to regard his approach as evolutionary;
- institutionalised theory of economics originated by Thorstein Veblen was defined by him as “evolutionary” or “post-Darwinian” economics; the works of Adam Smith, Carl Marx and Alfred Marshall and many others' are defined as having an “evolutionary” character;
- occasionally, the term “evolution” is used in the implementation of different mathematical approaches to describe economic phenomena, e.g. the chaos theory; some computer stimulations use the mechanisms of selection and the game theory (compare Kwaśnicki, 1996, pp. 3-4).

Creative destruction

Unfavourable economic situation intensifies the phenomenon of negative selection of inefficient entities contributing to a change in the allocation of resources. J. Schumpeter abandoned the assumption of market balance between the demand and supply and balance in the enterprise – between the production size and price. According to him, the most important

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

factor shaping the behaviours of enterprises was competition understood as launching new products, technologies, resources, organizational forms. Insolvency of an enterprise does not result from unfavourable external conditions, but delayed adjustment to new market requirements or lack of such adjustment. For this is the consequence of implementing innovations by the competitors. J. Schumpeter (1942) considered the bankruptcy of an enterprise as a necessary component of economic growth in macroeconomic terms (“creative destruction”). Insolvent enterprises release the assets involved, the use of which may be enhanced due to the innovations implemented and better organization (Pieńkowska, 2005, p. 21).

Schumpeter's proposal was to treat a business entity not as somebody (or something) maximising their behaviour in any conceivable way, but rather as entities pursuing to improve their situation in comparison to the situation of other business entities (Kwaśnicki, 1996, p. 22).

Armen A. Alchian searched for the ways of replacing neoclassical concept of maximising through the biological theory of natural selection. The application of the “natural selection” idea in the company's model was discussed by Alchian for the first time in 1950 and two years later by Penrose (Alchian, 1950; Penrose, 1952). Alchian argued that competition between companies is not defined by the motive of maximising profit but by “adjusting, imitating and based on the trial and error method search for the possibility to increase their profit.” Therefore, “those, who obtain *positive profit* survive; and those who lose are eliminated from the market” (Alchian, 1950, pp. 211-213), which is the statement in the spirit of Darwinism. The work of Alchian was a significant, preliminary step towards the use of evolutionary analogies in the construction of mathematical models of economic changes. The scholar states that “the economic equivalents of genetic transfer, mutation and natural selection is imitation, innovation and positive profit” (Alchian, 1950, p. 220). Alchian presents the manner of the analysis of the companies' behaviour in the competitive environment in a suggestive way (see Kwaśnicki 1996, p. 22).

The evolutionary theory situates itself on the axis beginning with the theory of resources and capabilities. According to the theory of resources and capabilities (Noga, 2009, p. 177), enterprises which are not able to overcome the so-called Penrose effect [1959] (the surpluses of the growth advantages over the growth costs, also called the costs of E. Penrose), go bankrupt. According to Penrose (1959), the costs of the growth of enterprises are all additional costs, born by an enterprise during the growth, which were not born by it when it was smaller. The elements of a structure

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

("genes") of the evolutionary theory are routines. The approach proposed by Alchian and Penrose was developed and, more importantly, ingrained in the evolutionary paradigm by Nelson and Winter in their numerous articles and books - e.g. Winter (1964), Nelson and Winter (1980, 1982). In the evolutionary approach, both quantitative and qualitative changes are emphasised. The ways of making decisions by a human being are modelled in a manner which is much more satisfactory and closer to reality.

According to Marshall, companies have a defined period of duration in the intergenerational model, in which with the passage of time, family businesses lose their vitality and longevity originated by their founders systematically (Metcalf, 2007, p. 2).

Some of Marshall's successors, including the evolutionary researchers, have combined thinking about the companies and sectors in the category of population. Marshall perceived the analogy between a sector and a forest. He claimed that a sector is like a forest, which may grow and develop independently and transform and organise itself as it combines growing and falling trees becoming a mature and, it seems, a static plantation of similar and stationary members (Bloch & Finch, 2009, p. 141).

Marshall (1920, p. 280) argued that each new withdrawal from the market is an experiment, which may fail. Those, who stay on the market pay for their failures and the failures of others. Marshall underlined fair and harmonious adaptation rather than creative destruction in the explanation of the economic development. He drew attention to the fact that companies may survive more by benefiting from the environment rather than transferring benefits to it. Enterprises and sectors are in the centre of research of contemporary evolutionary economics, starting with the model research of Winter and Nelson (1982).

Steindl points out that entrepreneurs demand the risk premium for these investments, which are characterised by uncertain return, as compensation for the exposure to risk related to the variance of returns, extended to the risk of bankruptcy. Risk premium increases together with the sum of financial means necessary for the company in relation to equity. Steindl confirms the Kalecki's principle of increasing risk (Kalecki, 1937, pp. 440-447). Both small and big companies come across various opportunities to undertake an activity with a higher risk, which are characterised by a higher rate of return because of the economics of scale. Sufficiently high rate of demand growth in a sector may attract new entries of companies (Bloch & Finch 2009, p. 152). Initially, growing companies react to the unplanned increase of production capacities by the engagement in the aggressive price

or sales competition. Marginal companies are not able to cope with aggressive competition because of a lower gross profit margin so they are forced to transfer the market share to growing companies. Some of them go bankrupt and leave a sector. Decreased gross profit margins also discourage the entries of new companies into a sector. Concentration of a sector increases in the absolute categories in a sense that together with the decrease of the number and the size of margin companies, the decrease of the total sales volume of small companies and the increase of the total sales volume of big companies take place as well (Steindl, 1952, 1976, p. 42-43).

The survival of the fittest on the market

An enterprise (Noga, 2009, p. 179) is an organisation and an institution, a peculiar “phenotype”, which is the result of the interaction of a routine set (peculiar “genotype”, “hereditary” factors) and the environment conditions. Routines play a similar role to the genes in a living organism. Routines in an enterprise may be divided into:

- technical, allowing to manufacture,
- marketing, allowing to acquire better resources and to sell them,
- investment, allowing to create new production capacities,
- diversification, allowing to compete,
- tacit and idiosyncratic knowledge,
- innovative changes.

Changes of a routine set of an enterprise lead to evolutionary (stochastic) changes of its boundaries on the market, enterprises develop or go bankrupt. The objective of an enterprise is as fast entry into the market as possible (an enterprise using innovations is in the best situation) in order to achieve a high return on equity and to remain as long as possible on the market with the falling return on equity with which the competition cannot remain on the market (natural selection). The economy requires the development of routines (memories), which the market does not have but which enterprises and consumers have.

Competing between enterprises as a routine set and the ability of those routine sets to react to the environment contribute to the fact that the economy sectors (markets) evolve to the structures, in which only a certain group of enterprises, e.g. an oligopoly, remains. Yet, it is a stochastic process, non-deterministic, which is tried to be modelled, e.g. by means of Markov chains (probability distributions in time), as it is done in case of evolution of living organisms.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

The relation between the development of enterprises and the overall economic advantages takes place through the natural selection. However, according to the principles of Lamarck and, therefore, not of blind selection, but the one, in which those, who are better at shaping routines (“genes”) and adjusting to the environment, survive. Macroeconomic policy does not have to select enterprises (routines sets) as it is done by the evolution. Macroeconomic policy may temporarily sustain weak routines but in a longer period (of evolution) they will be eliminated from the market. In this theory enterprises are “the engine” of growth and development. Selection results in the appearance of the most healthy enterprises, creating “healthy” growth, based on strong microfoundations (Noga, 2009, p.180).

The major representatives of the evolutionary theory are: Winter (1964, 1982, 1986, 1987a, 1987b), Nelson (1996), Nelson, Winter (1982, 2002), Teece, Dosi (1991), Mangolte (1992) and Kwaśnicki (2000). The main representative of the evolutionary economics in Poland is W. Kwaśnicki, who has formulated the evolutionary model of industry development (see Kwaśnicki, 2000).

Some of the basic evolutionary ideas were borrowed by Spencer from the biologist Jean Baptiste de Lamarck (1774-1829) and the embryologist Karl Ernest von Baer (1792-1857). In his works, the scholar often referred to biological analogies and compared society to a living organism.

In two essays from 1852, a few years before the publication of Darwin's *On the Origin of Species*, Spencer had presented an original concept of evolutionary development. In these essays, Spencer presented the evolution as “a shift from undefined, inconsistent homogeneity to defined, consistent heterogeneity by a constant variation.” The evolution is equivalent to the progress and the increase of effectiveness towards a certain ideal condition. Spencer perceived the evolutionary process as a shift from lower forms of an organisation or forms of life to higher ones, from worse ones to the better ones. He argued that complexity is usually related to the better forms, which are advanced and more adjusted (compare Kwaśnicki, 1996, p.12). Organisms which manage to survive are not necessarily the best ones, only relatively good. Organisms adjust to the local conditions in order to survive and to leave their offspring. The principle of the survival of the fittest was applied in the economics by the introduction of the principle of maximising profit - the company, which survived had the biggest profit. The unadapted entities, or least adapted are eliminated from the market. Similarly to the principle of “the survival of the fittest”, the principle of maximising is in contradiction with experience; enterprises which generate relatively high

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

profit survive on the market. Herbert Simon underlines the need to replace the concept of maximising with the concept of satisfying achievements (Kwaśnicki, 1996, p.12).

Veblen perceived institutions as the analog of biological genes. He interpreted social and economic development in the categories of Darwinian selection. "The life of a human being in society, similarly to the lives of other species, is the struggle for survival and, therefore, it is the process of selective adaptation. The evolution of a social structure was the process of natural selection of institutions." (Veblen, 1899, p. 188) (see Kwaśnicki, 1996, p. 18).

**The relation between "age" and the number of bankruptcies.
The survival of enterprises on the market**

The tests aiming to determine if there is a correlation between age and the number of bankrupt enterprises were carried out in the United States. S. Thornhill and R. Amit (2003, pp.7, 14-15) addressed the above-mentioned issue. The scholars carried out tests on 339 enterprises which went bankrupt in 1996. The lack of skills and experience in the field of the company management and a limited possibility of raising capital necessary to develop were the main problems of the enterprises which went bankrupt up to 2 years from the moment of setting up. The objective of the companies, which just enter into the market is the survival, managers and owners are very flexible and they try to adjust to the environment. Enterprises do not follow the changes in the competitive environment (Korol, Prusak, 2005, p. 64-67).

Similar tests were conducted in Europe and they had a questionnaire survey character as well. The above-mentioned analysis concerned such countries as the United Kingdom and Germany. From these it appeared that the lack of financial means was the biggest problem of enterprises. Respondents also drew attention to the insufficient flow of information, which arose from the lack of knowledge of entrepreneurs on the prevailing situation on the market.

A number of theories, whose purpose was to explain the probability of the survival of business entities on the market was developed in the economic literature. One of them is the liability of smallness concept, related to the liabilities of small enterprises. According to it, small companies have smaller chances to survive. P. Preisdorfer & T. Voss (1990, p. 107-129) claim that smaller enterprises are frequently incapable of competing with

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

bigger companies. Small enterprises often do not have permanent outlets and because of this they are not able to provide their employees with such possibilities of development as the ones which are offered by bigger companies (Mączyńska, 2009, p. 113). It is also worth to indicate the liability of newness concept concerning the liabilities of new enterprises. Research on the correlation between the duration of business entity activity on the market and the survival plays an important role. According to this concept young companies leave the market faster than the older companies. Competition the new enterprises must cope with is one of the underlying reasons behind this. Entering the market, the enterprises compete with organisations with well-established positions and they must gain reputation in order to acquire clients, suppliers and investors.

According to the concept, which has its roots in the industrial economics, only after entering the market are enterprises able to state if they can exist on it. The representatives of this approach search for the factors which will allow the enterprises to survive on the market and, in a broader sense, not only on the level of the company but also on the level of the whole economy. Assuming that structural characteristics of industry, such as market entry and withdrawal barriers and the intensity of applying new technologies exert a significant influence on the survival and the development of new enterprises on the market.

Corporate bankruptcy case of Beta: Lessons learned

Even though the scenario and stages of the course of crisis as well as its signs are similar for many bankrupt enterprises, the process is different in younger enterprises and in mature entities, which have been operating on the market for many years (Argenti, 1976, p. 121). Depending on the age of a business activity, different factors have impact on it in particular periods. The trajectory concept of J. Argenti was confirmed by the research carried out by S. Thornhill and R. Amit. According to the results, there is a correlation between the age of enterprises and the number of bankruptcies. Young companies are heavily burdened with the risk of bankruptcy. The main objective of business activities in the initial phase of their existence is the survival.

The enterprise Beta, selected for research, had its registered office in Oborniki Śląskie. The company had two owners and it operated a business from 27 February 2003. Initial capital amounted to PLN 50,000 (100 shares, worth PLN 500 each). The main objective of the business activity

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

was the wholesale of fruit, vegetables, meat and meat preparations, milk products, eggs, edible oils and fats, alcoholic and non-alcoholic beverages, tobacco products, sugar, chocolate and confectionery, tea, coffee, cocoa and spices, the retail of food, beverages and tobacco products. The balance sheet as at 30 November 2005 indicated the loss exceeding the sum of the initial capital and the assets of the company did not suffice to satisfy the repayment of receivables and the company lost financial liquidity permanently. The situation was caused by the circumstances independent of the company, in particular by the decline in the sales of food products of about 50%. As a result, on 13 December 2005 a bankruptcy petition including the liquidation of assets was filed in the District Court in Wrocław. The company settled all liabilities owed to the Tax Office, the Social Insurance Company (ZUS) and the employees.

The Beta company lost financial liquidity. As it is clear from court files, this condition was caused by the external causes. The sale of food products decreased by about 50%, which contributed to their expiry and withdrawal from sale. Enterprise struggled with the crisis caused by strong competition and a fast growing food discount, which used dumping prices. The Management Board of the company tried to defend itself against bankruptcy and, therefore, introduced the modernisation of the sales department, organised a self-service point of sale and expanded sales portfolio. It organised the promotion of sale in order to acquire new customers. The company reduced costs by reducing remuneration, redundancies and it decreased store space. Despite the undertaken actions, the revenues from sale decreased.

On 30 November 2005 the assets of the company amounted to PLN 375,237.91, almost 3 times less than in the previous year. The company had only current assets, in which inventory had the biggest share - 72%, short-term trade receivables from other entities constituted the remaining share. Short-term liabilities which amounted to PLN 564,011.95 dominated in liabilities. Equity of the Beta company constituted a negative value. The net loss in the amount (PLN -242,996.82) exerted the biggest influence on this item.

In 2005 a current ratio amounted to 0.67. It means that the Beta company had problems with the settlement of its liabilities from current assets. Short-term liabilities far outweighed current assets of the enterprise. The level of a quick ratio indicator was not satisfactory as well, since it amounted to 0,18. It was caused by the high level of inventory, which in case of this company was negative. It is clear from court files that the excessive

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

amount of inventory of food products became expired. A receivables rotation ratio amounted to 21.44, which means that the company conducted too restrictive policy of debt collection. A liabilities rotation ratio indicates the emerging problems of the Beta company with the settlement of liabilities. The reason of this situation was the significant growth of liabilities in relation to revenues. Despite the undertaken activities, whose aim was to emerge from crisis, the enterprise was not able to further carry out its business activity (tab. 2).

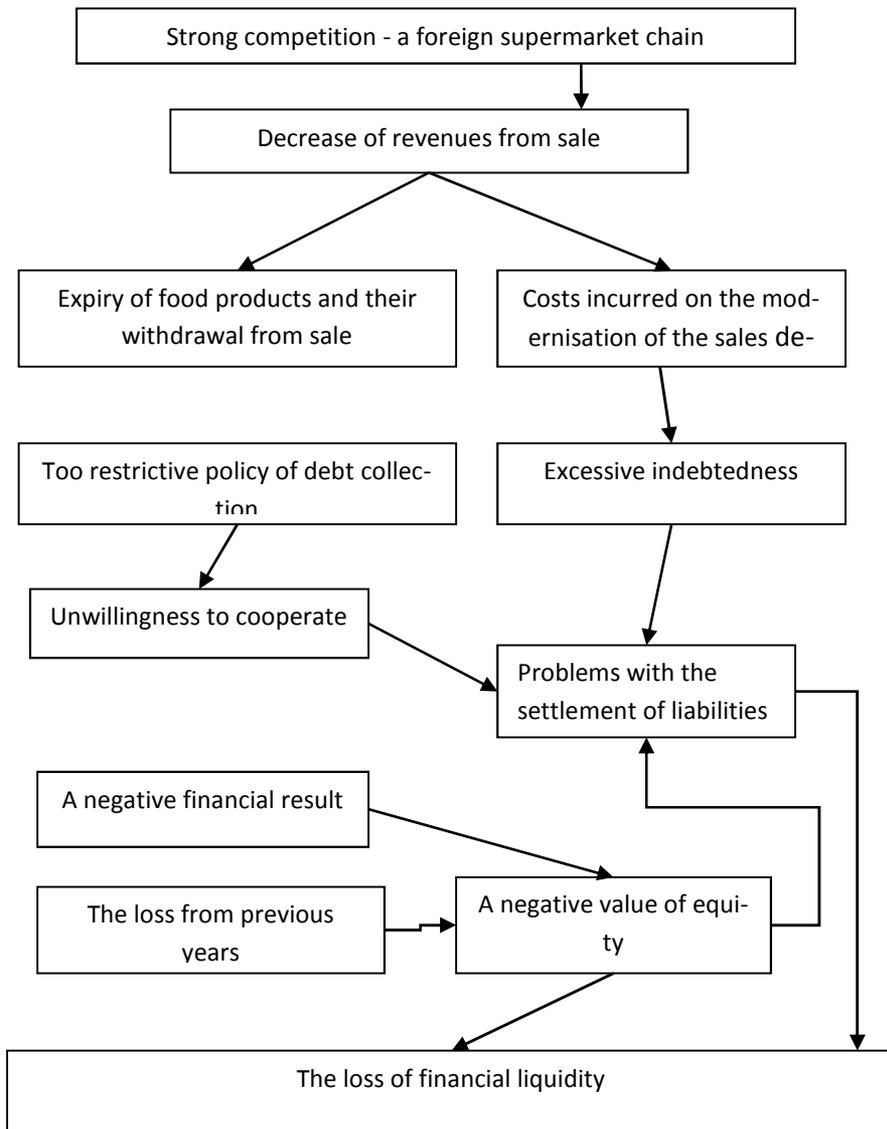

Table 2. The reasons of the Beta company bankruptcy

The reasons of bankruptcy	Specification
- strong competition,	+
- decline in revenues from sale,	+
- increase of liabilities,	+
- loss from previous years,	+
- negative financial result,	+
- high level of indebtedness,	+
- loss of financial liquidity,	+
- excessive amount of inventory,	-
- lack of fixed assets,	+
- restrictive policy of debt collection.	+

The major determinant of crisis in its initial phase was the occurrence of decreasing sale share in the market, which is caused in many cases by the lack of a marketing strategy and an improper carrying out of marketing research (or its lack). The subsequent symptoms appear later, particularly those with a financial character. Permanent loss of financial liquidity was indicated as the main reason of insolvency. Additionally, the losses of the company in the previous years contributed to a difficult financial situation. Problems started from the expansion of foreign supermarket chains and markets. The enterprise lost its customers as the prices proposed by competition were much lower. Despite the actions aiming to lower business expenses, the company was not able to emerge from crisis. The problems related to the settlement of liabilities emerged. Subsequently, financial sphere factors occurred and, consequently, led to bankruptcy (fig.1).

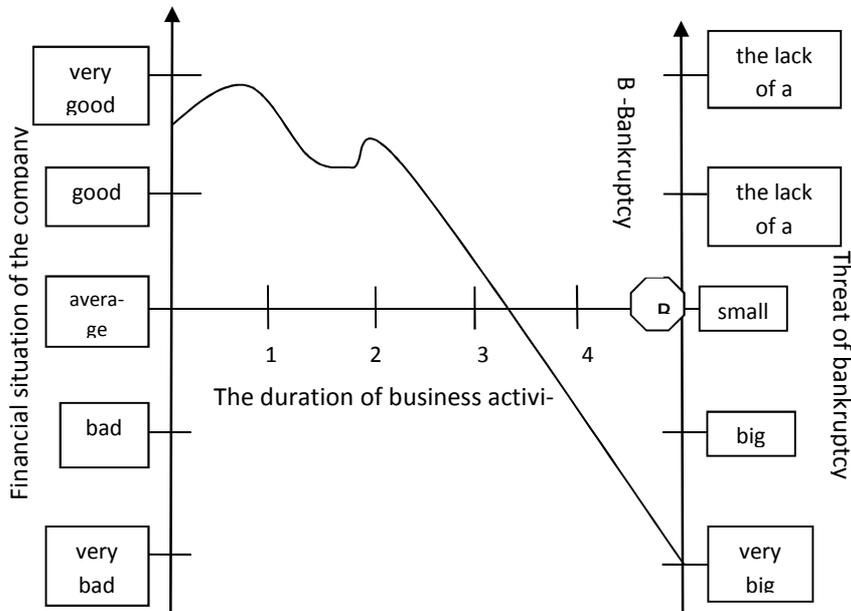

Figure 1. The mechanism of the Beta company bankruptcy

Source: Own research on the basis of information from insolvency files of the company.

The Beta company operated on the market for nearly 5 years, Within the period of two first years of its business activity, the financial situation of the company was good, and the enterprise was developing. Sales volume was at the appropriate level. After the second year of its activity, the financial situation of the Beta company deteriorated (fig. 2). The expansion of foreign market and supermarket chains exerted influence on this situation. The sale of products started to decline. The company undertook the activities aiming at the improvement of a financial situation but competition was very strong. The company started to bear losses, it was not able to settle its liabilities and it lost financial liquidity permanently. The owners were forced to file a bankruptcy petition.

Figure 2. The trajectory of the Beta company bankruptcy

Conclusions

1. Young enterprises are more vulnerable to the risk of bankruptcy. The discussed example inserts itself into research between “age” and the survival of the company. The survival was the main objective of the studied entity in the initial phase of its functioning. According to the evolutionary theory, the entities which are best adjusted to the market conditions survive on it. Despite many undertaken adjustment activities, the Beta company was not able to compete and to stay on the market and, therefore, it finally went bankrupt.
2. Creating the bankruptcy trajectory according to the methodology of J. Argenti, it was indicated that the financial situation of the Beta company deteriorated as a result of the emergence of fast-growing foreign super-market chains, which used dumping prices. The purpose of foreign competitors was to conquer the market on which the Beta company was operating and eliminating it by applying much lower prices. The sale of food products decreased which was connected with the expiry of products and withdrawing them from the sales. Defending against the crisis the Beta company introduced the modernization of the sales department, expanded product portfolio and organised the promotion of sales in order to acquire new customers. Unfortunately, those activities involved additional costs and, therefore, the revenues from sale were still falling. The enterprise borrowed excessively. Additionally, too restrictive policy of debt collection discouraged cooperation with the company. The company had serious problems with the settlement of liabilities. The business activity generated losses and equity constituted a negative value. All of these factors exerted influence on the permanent loss of financial liquidity and, consequently, led to submitting a bankruptcy petition by the Beta company.
3. The issue addressed in the article becomes increasingly important from the point of view of the entities whose aim in the initial phase of their functioning is, first and foremost, the survival. The discussed case of bankruptcy is a specific lesson on evolutionary economics, from which the analysed company did not draw proper conclusions. Despite the repeated attempts to emerge from a difficult situation and to implement adjustment actions, the market eliminated the ineffective entity. Corrective actions were undertaken too late. Apart from this, they were not sufficiently intense and effective. The achievements of the representatives of evolutionary economics, especially the one concerning “the survival

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

of the fittest”, should be particularly significant in the age of uncertainty and the increase of the bankruptcy risk in times of the world economic crisis. The complex issue presented in the article requires further in depth research and conclusions should not be considered in relation to the whole population of enterprises.

**A Model Assessing Innovativeness
of Administration Units Awarding Public
Contracts as a Tool to Conduct Economic
Policy of the State**

JEL Classification: *E1; E6*

Keywords: *Macroeconomic Policy; Policy Making; Innovations; Public procurement*

Abstract: In today's market economy factors concerning knowledge, new technologies and innovative solutions are essential for economic development. However, the Polish economy, despite its high innovation potential compared to other European Union countries, is characterized by a very low level of innovativeness. Implementing this potential is conditioned with an appropriate economic policy of the state and rational approach to its resources and legal solutions. One of the possibilities of such an action is the use of public procurement instrument through which it is possible to more effectively create demand for innovative products and services.

As shown by literature studies, the achievements of the subject literature associated with the creation of demand for innovations by public administration in Poland have been very modest. This gap is recognized the article and it attempts to build a model for assessing the innovativeness of these units. Network thinking methodology was used to build the model. As a result, after the identification of factors affecting the conduct of an innovative public procurement, a network of links was established between them and examined in terms of type, intensity and

**Proceedings of the 8th International Conference on Applied Economics

duration of exposure. Building a model according to the methodology, the opinions of experts have been used along with long-term observations conducted in the course of participation in all kinds of conferences and trainings. The model was also subjected to validation in two selected units.

Introduction

In recent years innovativeness has been one of the priority areas of economic policy in Poland and other EU countries. This policy, in line with the understanding of innovations as a driver of economic growth (Romer, 1986), is reflected in many documents at Community level, as well as the actions taken by the governments of many countries. However, while analyzing the position of Poland in the ranking of the EU innovativeness, it should be noted that its economy is showing a low level of this indicator and scores the fourth place from the end in comparison to the remaining EU Member States¹. Especially worrying is the insufficient activity reported in connection with the decommissioning of the institutional barriers and the lack of adapting public institutions to the needs of entrepreneurs.

It seems that there are several reasons behind a growing importance of innovations in the Polish economy. Firstly, the 20th Century witnessed a great technological revolution - especially in the field of telecommunications and informatics. This considerably accelerated the aging process of many products and services available on the market. This situation obliges the producers to multiply their efforts to generate innovations, especially regarding products and processes, as well as rapid changes in the structure of employment. Secondly, the Polish market economy has been slowly entering a state of maturity, and after more than 22 years of operation it requires new challenges and effective actions. For this economy to be respected in the European Union efforts should be strengthened and expanded in order to accelerate its development and its competitive position should be improved as well. Thirdly, the beginning of the 21st Century showed how much countries like India, Brazil and China did to improve competitiveness of their economies. To maintain its position as a strong European country Poland should, therefore, take steps to maintain and perhaps strengthen its economic position.

As we can see, there can be numerous motives for introducing innovations and they may involve internal and external sources (Freeman, 1994). They should focus on many aspects of economic policy, including the pub-

¹ The innovative position has been determined using the Innovation Union Scoreboard

lic procurement market, which in Poland has been growing rapidly and its estimated value amounted to approximately 8.76% of gross domestic product by 2013 (PPO, 2014, p. 27). Thus, the value of this market indicates that the analysis of creating demand for innovations through public procurement system (and thus the use of the existing potential of this system) is a very important economic problem facing the Polish economy. Despite the lack of empirical achievements in this regard, the examples of highly developed countries show that through the effective use of existing resources and legal status (through solutions used by public administration) innovativeness of many economies could be raised.

Innovative potential inherent in the system of public procurement, as well as the lack of comprehensive research on this issue, have led to an attempt to build a model for assessing the innovativeness of public administration entities awarding public contracts. This model is a proposal of the first in the literature system recognition of key factors related to public procurement, which affect the innovativeness of the Polish economy. Moreover, such an assessment can be useful for decision makers for an effective, and most importantly, fair allocation of budgetary resources to the bodies responsible for organizing legal tenders in our country, as well as comparing them to responses favoring the creation of demand for new products and services.

Methodology of the research

According to J. Gmurczyk, in case of such complex issues as innovativeness, system thinking seems to be almost necessary (Gmurczyk, 2014, p.32). Network thinking methodology has been used to build the model to assess the innovativeness of public administration entities involved in public procurement. As a result, after the identification of factors affecting the conduct of an innovative public procurement, a network of links has been established between them and examined in terms of type, intensity and duration of exposure. This identification was made possible as a result of discussion in a group of experts dealing with procurement on a daily basis².

Network thinking methodology based on the cooperation of those involved in the analysis of the problem posed in front of them, provides very objective results. In this sense it certainly deserves to be called a moral methodology. Although it takes much more time than a simple methodolo-

² These people form a group of 43 postgraduate students participating in the course titled "public procurement and public-private partnerships."

gy of cause and effect, it also avoids the pitfalls of linear thinking and taking "shortcuts" and finding numerous unpleasant surprises. The methodology requires the use of a simple yet very precise language. Many of the concepts, definitions and problems require, therefore, the analysis and extensive consultations of participating experts. This is of great importance when it comes to a critical attitude toward the discussed problems. As stated by A. Piekarczyk and K. Zimmiewicz, the use of network thinking methodology allows us to discover the various limitations and barriers present in the decision-making process, which in the case of the provision of innovative public procurement is an extremely important issue.

The construction of a model for assessing the innovativeness of Polish public administration entities awarding public contracts

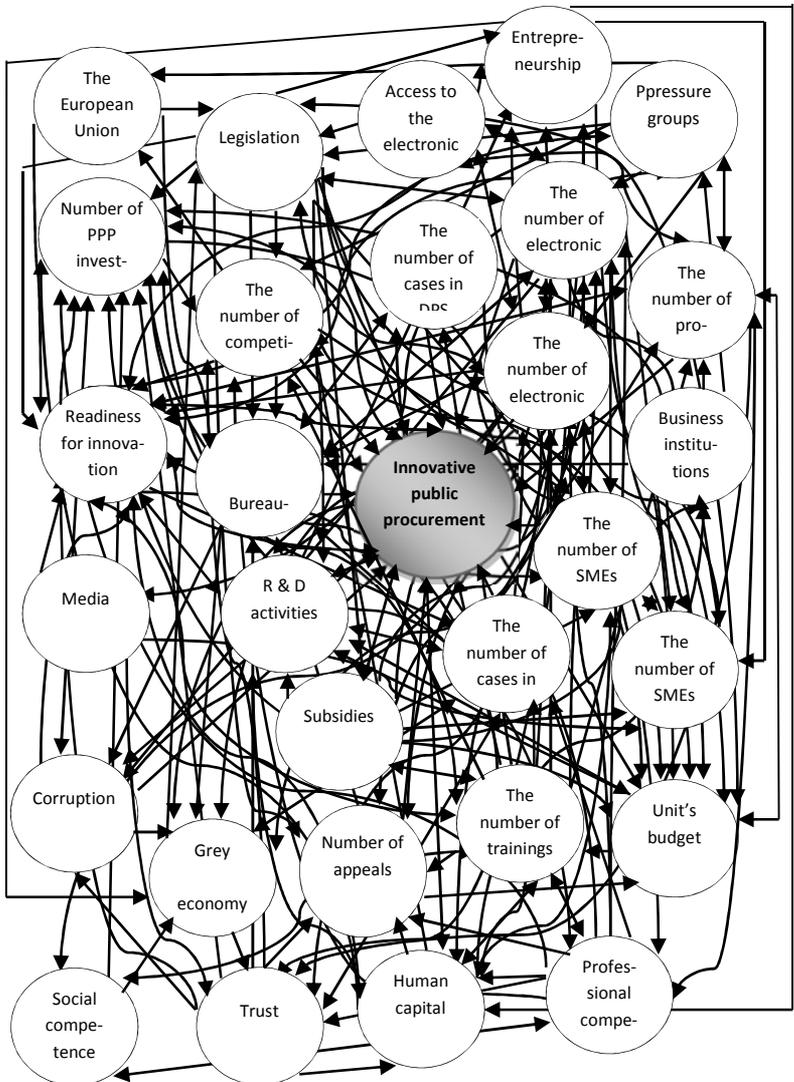

According to the network thinking methodology, it is necessary to illustrate the problematic situation first. For the assessment of entities purchasing innovative products and services, the problematic situation is to identify the elements included in the network of connections formed by the contract with both proximal and distant environments.

Innovative public procurement had to appear in the center of the created network because the objective is to develop a model for assessing the innovativeness of public administration through the prism of public procurement contracts. This type of procurement is created by public institutions, which simultaneously constitute one of the most important stakeholders influencing the launch of the award of these contracts and through this prism it is necessary to assess entities awarding public contracts. The network of connections between the factors influencing the solution to the problem situation is shown in Figure 1.

The next step should be to analyze the interrelationships between the various factors in the network in accordance with the adopted network thinking methodology. From a point of view of impacts, isotropic (prefix +) and opposite (sign \square) interactions have been assumed. These designations, however, have not been provided in the figure due to their low readability.

The next step in the analysis of network thinking is to create an influence matrix (Table 1). For this purpose it is worth using a spreadsheet, where the individual rows and columns are included in the value of the intensity of interactions between factors. Then it is necessary to add up the rows and columns that show activity (sum of A) and reactivity (sum of P).

Source: own study.

High values obtained in the "sum A" column mean that the factor has a strong impact on other factors, while low values mean that its influence is small. High values obtained in the line "the sum of P" mean that the factor

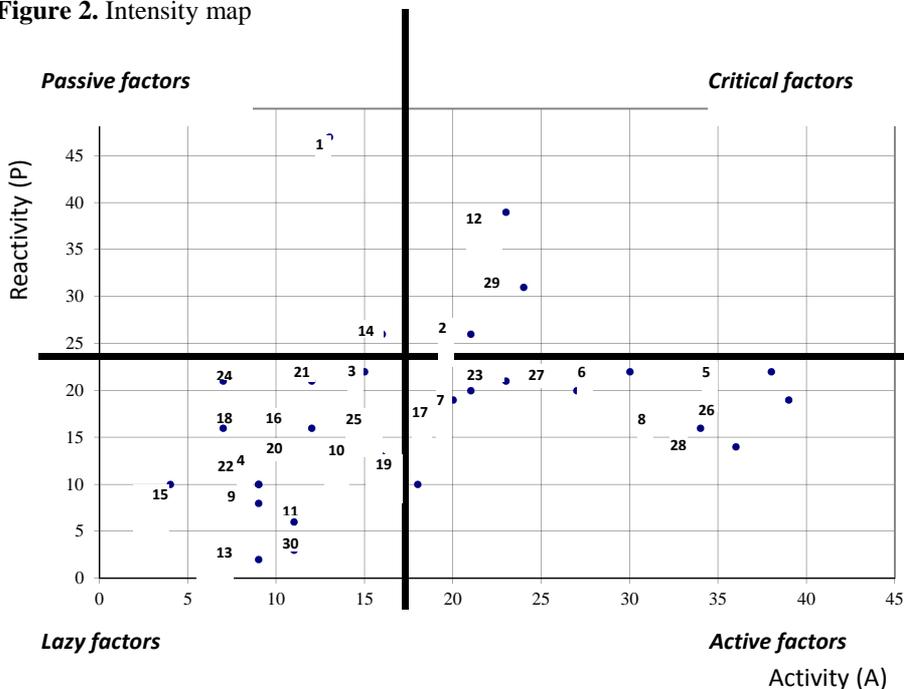

was heavily influenced, and low mean that it is subject to a weak influence of other factors.

The matrix of influence is an indispensable tool for the preparation of the so-called intensity maps. After its creation, it is possible to determine which of the previously separate factors are active, critical, passive or lazy.

From the point of view of the construction of a model (for assessing the innovativeness of public administration awarding public contracts) for further analysis only those factors will be admitted that constitute the two first-mentioned groups.

Intensity maps (Figure 2) is a two-dimensional graph wherein the values for the activity of a factor have been placed on the horizontal axis, while those regarding reactivity - on the vertical axis.

Figure 2. Intensity map

Source: own study.

It is very important to objectively lead the verge of splitting between the categories of factors obtained in the matrix of influence, in order to identify active, critical, passive and lazy factors. It is assumed that the dividing lines

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

will extend in places that are formed by dividing the maximum value of A and P by 2. Thus obtained values are $A = 19.5$ and $P = 23.5$.

On the basis of the intensity maps it is possibly to finally emerge active, critical, passive and lazy factors. Table 2 shows the distribution of these factors along with the values for the activity and reactivity.

Source: own study.

The maps of intensity show that there are three critical factors that strongly influence other elements, but are also heavily influenced themselves. However, it seems that only the first and the last (the number of PPP investments and the unit's budget) may be under the control of public administration. On the other hand, the individual unit's budget depends in its income part on the distribution of funds by the government and the local government and to some extent the contracting authority does not affect it. By using it, this institution can cause considerable changes especially if it allocates an essential part of the funding in innovation. Today the structure of the budget is dominated by expenditure on the wages of employees.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

The second group of factors (and the most desirable from the point of view of creating demand for innovative public procurement) is the group of nine active factors. They strongly affect innovative public procurement, and most importantly, they are not subject to strong influences themselves. Among these factors, there was legislation that - like previously the unit's budget - does not depend directly on the actions of the contracting authority, but may, however, play a very important role in creating the demand for modern supplies, services or construction works.

The next step in the deployment of network thinking methodology in the process of creating a model to evaluate the innovativeness of public administration entities that create demand for public procurement should be to determine which critical and active factors are manageable and non-manageable, and which can be measured. Thus, it is necessary to use the following factors: the number of PPP investments, willingness to innovate, the unit's budget, the number of electronic biddings, the number of electronic auctions, the number of orders with the pro-environment criteria, legislation, the number of SMEs winning tenders, confidence, the number of trainings received by authorities, human capital, professional competence.

To objectively assess changes in a public administration unit, and thus in the whole national economy, it is necessary to rely primarily on such factors which are directly influenced by the audited entity. Therefore, the starting point in the selection of the factors used for its evaluation should be an ability to influence them by deliberate actions taken by this entity's management.

Such reasoning results in a situation where it is necessary to use only the manageable factors, separated within the framework of network thinking methodology. They include: the number of PPP investments, unit's budget, the number of electronic biddings, the number of electronic auctions, the number of pro-environmental contracts, the number of trainings received by authorities and professional competence.

Of the seven aforementioned factors two are critical (the number of PPP investments and the unit's budget), while others remain active. Therefore, the critical factors strongly influence other elements, but they are also subject to a strong influence and their weight in the model of innovativeness assessment must be smaller as it is difficult to predict the effects associated with their use. Therefore, one should be very careful in using these factors, which may not necessarily be related to the reluctance of officials to introduce innovative solutions in public procurement.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

In order to select the weight of various factors involved in the model evaluating the innovativeness of public administration entities awarding public contracts, one can use a methodology based on the proprietary model of analytical hierarchy (Borowiec, 2008).

The assessment of the validity of individual factors in this model will be based primarily on the strength of activities they possess, read from the matrix of influence developed in this chapter. Table 3 contains a list of manageable factors with their assignment to a specific group, and an indication of the strength of their influence (activity) regarding the other factors included in the network of public procurement system.

Table 3. Manageable factors in the construction of a model for assessing the innovativeness of Polish public administration entities awarding public contracts

A manageable factor	Group of factors	Factor activity
Number of PPP investments	Critical	21
Unit's budget	Critical	24
The number of electronic biddings	Active	38
The number of electronic auctions	Active	30
The number of pro-environmental contracts	Active	21
The number of trainings received by authorities	Active	39
Professional competence	Active	36

Source: own study.

As it can be seen from Table 3, the most important factors in terms of the impact on other components of the system are: a number of trainings received by authorities and the number of electronic biddings. Most problems arise with the factor related to technical competence. They are understood in the literature in very different ways and exhibit significant difficulties for the process of measurement. For example, A. Poczowski believes that competence is a broader concept of qualification and includes the total assets of human characteristics that make up a causal link with high or above average effects of work, which have a universal dimension (Roszkowski, 2004). In addition to knowledge there are also: loyalty, trustworthiness, honesty, perfectionism and self-improvement. Yet another definition is given by M. Armstrong - according to him competencies include what an employee should know, what he or she should do and how to do it (Whiddett, Hollyford, 2003).

It can be assumed that professional competence is strongly related to knowledge received by employees. Therefore, the model assumes that the analyzed factors: the number of trainings received by authorities and professional competence are highly similar to each other. However, since the first one can be expressed in a very simple manner by means of a measura-

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

ble value, in the construction of the model the second one can be skipped. Finally, six variables were incorporated into the analytical hierarchy method used to determine the weights of individual factors included in the model.

To objectify the values resulting from comparisons, it is necessary on the basis of Table 3 to determine the relationships between factors in terms of their activities and bring them down to the values used in the method of analytical hierarchy. Table 4 shows the relationships between the factors, resulting from dividing their activity by itself.

Table 4. Relationships between the factors associated with their activity

	The number of PPP investments	Unit's budget	The number of electronic biddings	The number of electronic auctions	The number of pro-environmental contracts	The number of trainings received by authorities
The number of PPP investments	1	0.87	0.55	0.7	1	0.54
The unit's budget	1.14	1	0.63	0.8	1.14	0.61
The number of electronic biddings	1.81	1.58	1	1.27	1.81	0.97
The number of electronic auctions	1.43	1.25	0.79	1	1.43	0.77
The number of pro-environmental contracts	1	0.87	0.55	0.7	1	0.54
The number of trainings received by authorities	1.86	1.62	1.03	1.3	1.86	1

Source: own study.

As it is apparent from the table, the maximum value obtained in the comparison of the various factors with each other is 1.86. This means that it should correspond to the value of "9", which arises from the comparison of two factors, one of which is predominant over the other. Since the minimum value in the method of analytical hierarchy is the number "1", we should calculate the difference between the maximum value (1.86) and this number and divide the result obtained by 9, assigning consecutive intervals with individual severities. The severities obtained in this way, which correspond to the different intervals, can be found in Table 5.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

Table 5. Intervals corresponding to the degrees of importance (severities) in the method of analytical hierarchy

The obtained range of values	Severity
1.00 - 1.07	1
1.08 - 1.16	2
1.17 - 1.26	3
1.27 - 1.36	4
1.37 - 1.46	5
1.47 - 1.56	6
1.57 - 1.66	7
1.67 - 1.76	8
1.77 - 1.86	9

Source: own study.

Now in place of the values in the various ranges it is necessary to assign the respective values of Table 4 with the corresponding degrees of importance (severities) of Table 5. Apart from values <1 we obtain data summarized in Table 6.

Table 6. Severity levels resulting from the comparison of the activity of factors

	Number of PPP investments	The unit's budget	The number of electronic biddings	The number of electronic auctions	The number of pro-environmental contracts	The number of trainings received by authorities

The number of trainings received by authorities	9	7	1	4	9	1

Source: own study.

Since, as noted earlier, the number of PPP investments and the unit's budget both are critical factors, which may involve a high risk of adverse reactions, it is necessary to increase the importance of other factors in rela-

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

tion to these criteria. It was assumed, therefore, that each factor in comparison to critical factors will have an extra degree of severity added to it. By adding a severity level in comparing the number of orders and the number of environmentally-friendly PPP investments, the ratio between the number of PPP investments and the number of pro-environmental contracts changed, and it is its inverse. Analogously, the degree of severity resulting from the comparison of the unit's budget to the number of pro-environmental contracts should be reduced by 1, so that these factors become equivalent.

Simultaneously, the missing degrees of severity in Table 6 are the inverse ratio of those degrees that are already in the matrix. For example, the ratio of the number of electronic auctions and the number of trainings received by authorities is the inverse of the degree obtained as the ratio of the number of trainings to the number of auctions. Thus, it amounts to $\frac{1}{4}$. After making the necessary corrections and additions we received the data presented in Table 7.

Table 7. Severity levels resulting from the comparison of the activity of factors

	Number of PPP investments	The unit's budget	The number of electronic biddings	The number of electronic auctions	The number of pro-environmental contracts	The number of trainings received by authorities
The number of PPP investments	1	1/2	1/9	1/6	1/2	1/9

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

After filling the matrix, it is necessary to calculate the 6th degree root value of the product of numbers within it. The degree of the root always depends directly on the degree of the matrix. The result is:

- for the number of PPP investments $\sqrt[6]{1 \cdot \frac{1}{2} \cdot \frac{1}{9} \cdot \frac{1}{6} \cdot \frac{1}{2} \cdot \frac{1}{9}} = 0,283$,
- for the unit's budget $\sqrt[6]{2 \cdot 1 \cdot \frac{1}{8} \cdot \frac{1}{4} \cdot 1 \cdot \frac{1}{8}} = 0,445$,
- for the number of electronic bidding $\sqrt[6]{9 \cdot 8 \cdot 1 \cdot 4 \cdot 9 \cdot 1} = 3,706$,
- for the number of electronic auctions $\sqrt[6]{6 \cdot 4 \cdot \frac{1}{4} \cdot 1 \cdot 5 \cdot \frac{1}{4}} = 1,399$,
- for the number of pro-environmental contracts $\sqrt[6]{2 \cdot 1 \cdot \frac{1}{9} \cdot \frac{1}{5} \cdot 1 \cdot \frac{1}{9}} = 0,413$,
- for the number of trainings for authorities $\sqrt[6]{9 \cdot 8 \cdot 1 \cdot 4 \cdot 9 \cdot 1} = 3,706$.

The next step in determining the weights of factors included in the model for the assessment of innovativeness of public administration units awarding public contracts is summing these values:

$$0,283+0,445+3,706+1,399+0,413+3,706 = 9,952$$

Calculating the sum allows for the calculation of optimal percentage weights for the factors included in the model:

- the number of PPP investments: $(0,283 / 9,952) 100\% = 2,84\%$,
- the unit's budget: $(0,445 / 9,952) 100\% = 4,47\%$,
- the number of electronic biddings: $(3,706 / 9,952) 100\% = \mathbf{37,24\%}$,
- the number of electronic auctions: $(1,399 / 9,952) 100\% = 14,06\%$,
- the number of pro-environmental contracts: $(0,413 / 9,952) 100\% = 4,15\%$
- the number of trainings for authorities: $(3,706 / 9,952) 100\% = \mathbf{37,24\%}$.

Having determined the percentage weight of each factor included in the model, we can proceed to its presentation. Its final form has been shown in Table 8.

Table 8. Model for assessing the innovativeness of Polish public administration entities awarding public contracts

Factor	The method of calculation (a)	Weight (b)	The result (a x b) [%]
The number of PPP investments	the number of orders leading to contracts in the form of PPP / total number of cases	2,84%	___ x 2,84% = ___
The unit's budget	the amount of the expenses associated with the purchase of innovative procurement / total public procurement expenditure	4,47%	___ x 4,47% = ___
The number of electronic biddings	the number of cases in the electronic bidding / total number of cases	37,24%	___ x 37,24% = ___
The number of electronic auctions	the number of cases using electronic auction / total number of cases	14,06%	___ x 14,06% = ___
The number of pro-environmental contracts	the number of cases with pro-environmental criteria / total number of cases	4,15%	___ x 4,15% = ___
The number of trainings received by authorities	the number of trainings related to innovative public procurement / total number of trainings received by employees	37,24%	___ x 37,24% = ___
the sum of innovativeness			

Source: own study.

As regards the interpretation of the results obtained from the use of the model, it looks as follows:

- the results in the range of 100% - 76% - the highest innovativeness,
- the results in a range of 75% - 51% - high innovativeness,
- the results in the range of 50% - 26% - moderate innovativeness,
- the results in the range of 25% - 0% - low level of innovativeness.

Such a division is supported primarily by the European Union guidelines, which (for example in the field of green public procurement) planned to obtain the number of 50% of cases by the end of 2010. It is recommended to carry out the calculations associated with the use of the model on an annual basis by comparing the results with those of the previous year. This will provide an opportunity to indicate the direction of changes in the development of innovativeness in the analyzed entities awarding public contracts.

Since each model should be validated, also in this case the two units of public administration got their innovativeness indicators calculated. These entities were local government bodies performing similar functions in Po-

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

land and Germany³. The data were obtained during an interview conducted with the leadership of departments responsible for public procurement and on the basis of data collected by the audited entities. The obtained results are shown in Table 9.

Table 9. The use of the model to assess innovativeness in the selected units of public administration

Factor	Polish Unit			German Unit		
	Ratio	Weight	Result	Ratio	Weight	Result
LIP _{pp}	0	2.84%	0%	0.03	2.84%	0.08%
BJ	0.08	4.47%	0.36%	0.22	4.47%	0.98%
LLE	0.031	37.24%	1.15%	0.23	37.24%	8.56%
LAE	0.076	14.06%	1.07%	0.17	14.06%	2.39%
LZP	0.006	4.15%	0.02%	0.24	4.15%	1.00%
LSZ	0.12	37.24%	4.47%	0.51	37.24%	18.99%
Total Innovativeness	7.07%			32%		

Source: own study based on test results.

As indicated by the data obtained on the basis of the research on public administration in Poland and Germany, the native unit belongs to institutions that create low innovativeness, while the German one to those of moderate innovativeness. In both cases, there is a visible distance that has to be covered to catch up with the guidelines of the European Union. In fact, in the use of all the factors that create innovativeness, the Polish unit is still lagging behind its German counterpart. The largest differences can be seen especially in the use of green public procurement (the Polish unit generates only 0.6% compared to 24% on the German side), the number of electronic auctions (3.1% and 23% of cases respectively), and the number of trainings received by authorities characterized by issues related to the factors included in the model (12% and 51% respectively). The Polish example shows how much still remains to be done in terms of utilization of the factors that create demand for innovative procurement and how big distance separates our country from our western neighbors regarding work on improving the innovativeness of the entire national economy.

Conclusions

The resulting model can play an important role in economic policy-making related to the allocation of state funds to the state administration

³ The validation was conducted during the research internship in Germany.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

entities throughout the country. In such application, it can also act as an incentive function of these units because the results obtained in terms of innovativeness may influence future revenues associated with the development of regions or investment for local communities.

The annual assessment conducted by the entity or by a system that allows the introduction of online data will also allow the determination of the average level of innovativeness in public administration units dealing with procurement in the entire country.

Undoubtedly, it is important in this area to take appropriate legislative action, because as foreign experiences shows, only quick and efficient calculation of the rate of innovativeness allows for an appropriate use of the model. Therefore, its use is simplified to the maximum and does not require multiple procedures.

The model should also be applied to the micro level, because each unit of public administration can use it to monitor their progress in the purchase of more modern supplies, services and construction works. It is also of major importance in the use of electronic tools and the so-called green public procurement, whose weight is not large, but can be decisive in a situation when public entities maximize the number of trainings and the use of electronic tools.

Finally, we should mention the fundamental principle of economics associated with the use of the model. Using it ensures optimal results with the utilization of given resources. For example, it is difficult to imagine that while using the model, the money received by entities would be allocated to the trainings of employees not related to raising awareness on creating demand for innovative public procurement. This solution also seems to be a kind of a remedy for the lack of knowledge of contracting in the area related to negotiating procurement modes and the procedures of public-private partnerships.

The use of public-private partnership forced by the model is linked to another macroeconomic benefit. The use of this tool provides significant relief for the state budget expenditures related to the development of infrastructure and public services by replacing public capital with the private one. The benefits obtained this way can also translate into the desired concentration on the entire lifecycle of a given project, as in the case of proceedings conducted in the PPP efficiency and effectiveness formula, which are not counted for in the individual stages, but in relation to the total integrated cost throughout the lifecycle of the project. Finally, the big advantage associated with the launch of PPP in Poland on a larger scale is the

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

acceleration and improvement of the efficiency of project implementation. This is just an example of the benefits associated with the use of this tool.

The use of the model can also help to change the attitude of authorities in the field of environmental protection. Awarding these contracts and the associated influx of budgetary funds resulting from an increased innovativeness of certain units can successfully compensate for the often higher expenses they incur in connection with the purchase of green products and services.

Ultimately, there is also a chance to change the image of public administration. There is a still lingering notion that it is outdated and does not pass on good practices in the area of creating demand for innovative products and services to the private sector. It is worth mentioning that this change may lead to a greater confidence of citizens in these units as well as the entire economic system of the state.

Analyzing the importance of the manageable factors in the presented model, we can get an impression that only two of them dominate (the number of electronic biddings and the number of trainings received by authorities). In fact, these factors (given the results) seem to be crucial in conjunction with the next phase of network thinking methodology associated with the planning of strategies and actions. They provide the launch of processes associated with the use of electronic tools, which (as indicated by numerous examples) allow for huge savings of budgetary funds (which can be used for the purchase of modern products and services), as well as the efficient use of public funds for training of employees of public administration in Poland. Therefore, they essentially play a huge economic role as they allow obtaining significant savings not only in the administration of public institutions, but also in the entire state budget.

The model also carries certain limitations. Not every tender procedure can be carried out using the formula of public-private partnerships or as electronic bidding. The legislature has imposed limitations and only some of the proceedings can be realized in this way. It is also difficult to expect that the staff of the unit providing public contracts will be trained in the use of only the procedures associated with obtaining innovative products and services in public tenders. There exists a whole range of other activities that require the improvement of knowledge such as formulating the terms of reference, selecting criteria and procedures for evaluating an offer or judicial appeal proceedings that do not involve raising innovative procedures, but are necessary for the smooth functioning of individuals.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

Moreover, not all procurements have their ecological equivalents. Also, it is not always possible to analyze the balance of benefits and costs associated with them and maintain their green nature.

A threat to the use of the model can also lie in the so called "rat race" between public authorities striving for the greatest proportion of the budget regarding expenses related to tenders. This may result, among other things, in management trying to enforce participation in trainings on employees - withdrawing them from their daily duties and causing backlogs in the current work.

It is worth mentioning that the created model does not provide guidelines for creating innovations on the supply side of public procurement market. As we know innovation-oriented companies may find the problems that P.M. Simpson divided into four categories: too many changes for the sake of change, market risk, hostile attitude of the staff or an increase in costs (Simpson, Siguaw, Enz, 2006). Innovativeness of companies of different sizes may also be influenced by various factors such as, for example, the structure of the market (Audretsch, 1995), (Malerba, Orsenigo, 1996). These facts mean that in the future, it will be necessary to undertake a study on the construction of a model for assessing the innovativeness of enterprises participating in the public procurement market.

Protecting the Organization Against Risk and the Role of Financial Audit

JEL Classification: *D81; M42*

Keywords: *risk; risk identification; risk management; financial audit; internal audit*

Abstract: In the contemporary economic reality and organization's activities aiming at effectiveness and efficiency of functioning, a lot of significance is attached to a financial audit as an important instrument for protecting the organization against the risk factors. The aim of this article is to present theoretical and practical (on the basis of the examined example) aspects concerning the (internal) financial audit in the organization within the context of its assessment of the exposure to risk. The applied research methods are based on the method of conceptual analysis of the literature on the examined field, as well as on the case study of the auditing task. The results of the performed analyses and examinations allow to state that the financial audit constitutes an effective tool for protecting the organization against internal, as well as external risks. Each of the co-authors will contribute 50% of work to this article.

Introduction

A professional and unbiased financial audit (especially internal audit) constitutes for the management the main source of information about the organization. The appropriate provisions have introduced the obligation to

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

create the procedures of the internal control system, that is to say the collection of rules and mechanisms intended to assure proper functioning of the organization. The organization's management is also responsible for appointing an internal audit function that is independent from all the other sections of the organization. Information obtained from the auditor enables to assess whether the implemented internal control system fulfils its role. The environment of the examination includes the management style, culture of the institution, professional awareness of the employees and the organization's exposure to risk. The control mechanisms aim at preventing, detecting and repairing irregularities, in order to assure an orderly and effective conducting of the organization's activities, maintain conformity with the applied internal policies, secure the property, detect irregularities and frauds, timely prepare the required information about the financial situation etc. The subject carrying out the internal audit has also the task of identification and assessment of the risk areas, thus deciding about the form (selection) of the auditing tasks. Connecting the internal audit with the risk management results not only from the audit's definition presented by the Institute of Internal Auditors (IIA), but most of all from the increasing awareness of the fact that contemporary enterprises operate in the risk conditions, which are to be diagnosed and the mitigating mechanisms are to be implemented by means of control.

In this study the significance of the financial audit is presented on the example of the internal audit in an organization, focusing on demonstrating the relation between audit and risk. The fundamental aim was to recognize the auditing task in reference to the diagnosed or identified risks, at the same time acknowledging that the risk identification process constitutes a stage of the integrated risk assessment within the risk management process. Firstly, the study identifies the significance of the audit in the organization, taking into consideration the basic characteristics of the internal and external audit, in order to later direct the discussion to the internal audit and its connection with the risk management in the organization. What is then pointed out is the importance of identification of risk, as a stage of integrated risk assessment, for the auditing task concerning the travelling expenses and related costs – on the basis of a risk map of the examined organization. In the first – theoretical – part of the study the method of the conceptual analysis of literature was applied, whereas the second – practical (empirical) – part concerning the presentation of the auditing task was based on a case study.

The nature and objectives of audit versus the context of risk management

The term “audit” comes from the Latin word “audire”, which means to interrogate, examine, listen (Kiziukiewicz, 2009, p. 13). Internal and external audit can be distinguished basing on the criterion of the subject carrying out the audit. The external audit is performed by external institutions independent from the unit’s management, with the intention to examine the financial situation of a particular unit. In the local government administration the audit is carried out by the institutions that are independent from the local government, e.g. Regionalna Izba Obrachunkowa (RIO – Regional Chambers of Accounts), and in the government administration – Najwyższa Izba Kontroli (NIK – Supreme Chamber of Control). The external audit can also be outsourced to an external subject, e.g. an auditing company (as it is the case in the example examined in this study). On the other hand, the internal audit is performed by an own section (a particular position), which is distinguished in the organization’s structure. The auditor is the employee of a given enterprise (Kiziukiewicz, 2009, pp. 13-14).

An external audit is an instrument that in an active, objective and independent way evaluates the efficiency and effectiveness of the internal control system as well as the risk management process, yields an added value by means of revealing the defects, errors and weaknesses and by presenting the possibilities of increasing the quality of work (Saunders, 2002, p. 36). What is understood under the notion of added value is the improvement of the unit’s structure, which would enable generating a higher profit or achieving the same effect with similar expenditure (Kiziukiewicz, 2009, p. 16).

According to the definition of the Institute of Internal Auditors (IIA), “internal audit is an independent, objective assurance and consulting activity designed to add value and improve an organization’s operations” (Pickett, 2005, p. 3). Furthermore, according to IIA’s understanding of the audit, it helps to achieve the outlined objectives of the organization through consistent and systematic actions leading to the improvement of the effectiveness of the risk management, organization or control system (Czerwiński 2005, p. 10). Therefore it can be stated, as it arises from the definition of internal audit given by the IIA, that it is deeply embedded in the risk management, control and governance agenda.

Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

Table 1. Characteristics of the basic features of external and internal audit

Criterion	External audit	Internal audit
Objective of an audit	It serves the external subjects that want to get to know the financial situation of the unit	Bringing added value to the unit
Scope of an audit	Financial aspects of the activities	Financial, as well as non-financial scopes
The examined period	The events that occurred, especially the evaluation of data in the financial statements	Current state
Frequency of examinations	In most cases, once a year	According to the prepared schedule, during the whole year
Familiarity with the unit	The auditor gets to know the unit before or during the examination	The auditor knows the unit really well
Examining subject	The subject independent from the organization	The auditor employed in the organization

Source: Compilation based on the literature on the subject.

Internal audit is a regular examination of the correctness and effectiveness of the unit's (subject's) activities carried out over a longer period of time by an appropriate specialist – an auditor, in most cases employed in the unit on the full-time basis. Its role is mainly to evaluate and facilitate the functioning of internal control and the process of making management decisions. The developed reports are intended for the bodies managing the organization, including an enterprise. During the evaluation of the internal audit's functions the following areas and issues are taken into consideration (Herden, 2010, p. 105):

- internal audit independence,
- human resource capacity,
- knowledge and scope of internal audit function,
- information access,
- adequate funding and technology,
- existence of audit committees,
- stakeholder support,
- implementation of audit recommendation.

Any activities conducted by a given organization, examination and assessment of the effectiveness of the management control system, quality of the accomplished objectives, following the legal provisions and internal regulations, economy and effectiveness in using the unit's resources, as

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

well as the risk management process can constitute the subject of internal audit. It is assumed that “if internal audit (is to) enhance good corporate governance it should have acceptance and support of major stakeholders of the corporation. This includes shareholders, the board of directors, senior management, the audit committee as well as employees” (Herden, 2010, p. 103). The audit evaluates also the level of adjusting the activities to the previous recommendations and guidelines of an audit or inspection (www.mf.gov.pl., pp. 6-7) The auditing tasks should be the part of the annual audit plan. Therefore, such plan has to be based on the risk analysis carried out at least once a year or at any point when new risks are identified and when the exposure to the previously identified risks changes, as well as on the correlation with the objectives outlined by the unit’s management. It has to be remembered that the risk analysis is the stage of the risk management which is preceded by identification and the whole thing takes place at the stage, also a process, called the risk assessment (Bożek, 2010, pp. 99-100). In the international risk management standards, e.g. COSO II, AS/NZS 4360, FERMA, ISO 31000 the risk analysis constitutes a really significant process within the overall risk management process; it can be considered that it is a part of the enterprise risk management process (COSO II does not clearly divide the risk assessment into stages, however the reference to the risk analysis as the central process in the risk assessment process can be noticed (Zarządzanie Ryzykiem Korporacyjnym – COSO, 2007, pp. 45-55)). Most generally speaking, “risk analysis is performed both at the level of planning and the level of operations. It is an instrument for: facilitated long-term planning; used during drawing up a plan of an auditing task; allowing calculating and control risk of failure occurring in an audit of project; helping to evaluate the effectiveness and adequacy of a system of internal control” (Korombel, 2010, p. 117).

In the end, the auditor should collect information concerning the legal provisions regulating the activities of the organization, and more precisely, of all the significant areas of its activities. In exceptional justified cases there exists a possibility to perform an auditing task even though it was not considered in the plan. However, such procedure is applied occasionally – especially in case of a sudden occurrence of the risk factors and circumstances that may result in incurring significant financial losses, making harmful decisions, exposing to unnecessary expenses. The audit plan has to contain the following elements:

- the results of the conducted risk analysis,
- the results of the conducted human resources analysis,

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

- list of the risk areas, for which the assurance tasks will be performed,
- determining the time (in person-days) intended for the realization of particular assurance, advisory and revision tasks (Sławińska – Tomtała, 2009, pp. 91-109).

However, in order for the auditor to be able to efficiently fulfil the auditor's objectives, he should pay attention to the mission of the examined unit. Determining such mission constitutes an important stage in the unit's strategic planning as it outlines the general direction of activities and facilitates the management and employees to notice the elements responsible for creating advantage over competition in a long-term perspective (Kozmiński, Piotrowski, 2005, pp. 17-18)

Moreover, the auditor has to receive answers to the questions concerning the objectives of the unit's activities – whether they are measurable, if there are financial forecasts connected with their realization, as well as whether appropriate budgets were provided, if responsibility was placed on the people realizing the objectives and if these people are aware of the risks that may occur during the realization, whether the superiors meet the employees in order to discuss the progress and monitor the realization (Knedler, Stasik, 2005, pp. 41-44). The following situations are what should be of special interest to the auditor, focused on the assessment of the functioning mechanisms with respect to their correctness connected with the objectives' realization:

- lack of clearly stated objectives,
- vague organizational structure,
- improper process of planning,
- wasting the resources and lack of precision in communication with the employees (Knedler, Stasik, 2005, pp. 5-6).

Thus, generally speaking, the auditor's actions in the organization concentrate on the systematized activities which include:

- evaluation of risk areas,
- preparation of a plan of an internal audit,
- preparation of a program of an auditing task, performance of an auditing task,
- drawing reports from an audit,
- checking activities (Korombel, 2010, p. 116).

The work performed by the auditor should provide him with the answers to the essential questions:

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

1. whether the operational procedures and their control mechanisms enable the realization of the assumed objectives in an effective, and at the same time, economic and efficient way,
2. whether the assumed objectives are rational,
3. whether all the risks connected with the realization of the objectives have been identified,
4. whether the assumed procedures are followed and compliant with the provisions of law – if they protect against the occurrence of misuse.

Risks identification – significance, auditing objective

Quantification of risk is one of the most difficult parts of the enterprise risk management. (Emerling, 2013, p. 50). As it is emphasized in the literature on the subject, the understanding of the risk can be diverse, depending on the criterion of reference, the research area (on one hand, on the area of science, including social and economic science, on the other hand, for the fields of economic activity, including banking, insurances and finances), therefore there is no one and universal definition or attempt to specify this term (Bożek, 2013, p. 328). “Although is not easy to clearly define risk, it is often defined as uncertainty regarding which outcome will occur” (Seog, 2010, p. 7). Most generally speaking it can be assumed that the risk describes any situation (circumstances) which is an uncertainty as far as the occurrence (achievement) of the expected results is concerned (Harrington, Niehaus, 2004, p. 1). From the organization’s, and more precisely its business objectives’, point of view it is noticed that the risk is the possibility of incurring a loss caused by an event or a series of events that can have an adverse effect on the accomplishment of such objectives (Monahan, 2008, p. 3). Activities of the organization in a changing and unpredictable environment is of particular relevance to the objectives and strategic behaviour (Marzec, 2014, p. 395). And the “businesses too must manage their risks efficiently and effectively if they are to succeed” (Skipper, Kwon 2007, Preface). The implementation of an enterprise risk management system constitutes the most adequate approach to the risk which the organization is exposed to. “In the context of risk management there appear very significant determinants, namely the controls (constraints), which regulate, control or constrain the risk management process in the enterprise. Those are mainly: business risk management culture, resources, study parameters and plan” (Bożek, 2014a, p. 74).

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

The sources of risk might be as follows:

- direct hazards that result in non-accomplishment of the objectives,
- opportunities, offering the possibility of more effective accomplishment of the objectives (Czerwiński, 2005, pp. 68-70).

The internal auditor, in order to prepare the audit plan, prepares, according to his own professional evaluation, a documented analysis of the risk areas, which has a decisive influence on the selection of the auditing tasks (Sławińska – Tomtała, 2009, pp. 90-93).

The risk identification can constitute a separate process within the risk management process (Harrington, Niehaus, 2004, p.8; Rejda, 2010, p. 45 ff.). or, what is suggested in the enterprise risk management (ERM), it is a stage of the integrated risk assessment process¹. The risk opportunity identification process will be sufficient if at least the following objectives have been realized (Chapman, 2011, p. 160):

- the overall management of the business activity was understood,
- the risk identification process was not commenced before the business objectives were made explicit (without understanding the objectives it is not possible to undertake risk identification),
- risk identification was not commenced prior to a map or flow chart of the business process being prepared,
- department representatives participating in the identification process were senior enough to be knowledgeable in their area of specialization and were aware of both corporate lessons learnt and company risk exposure,
- the interdependencies between the risks were identified.

The following information is in particular used during the risk identification:

- objectives and tasks,
- legal provisions concerning the operation (possible changes in such provisions),
- organizational structure,
- results of the previously performed audits or inspections,
- results of the talks that the auditor conducted with the management and other employees of the organizational units.

The identified risks can be presented in the form of a risk map, where individual kinds of risk are recognized according to the significance / scale of results for the organization and the probability of occurrence. The exam-

¹ Approach visible in the standards of the risk management

ple of application of the map risk during the auditing task is presented in table 2. “To put it simply, the level of risk is obtained through comparison of probability with the effects of occurrence of a particular event” (Božek, 2014b, p. 49).

Example of the audit carried out in the organization for the task of delegating business trips and approving travelling expenses

The examined unit is a large organizational structure. It has within its frames an Audit Function which carried out the audit characterized below. Moreover, the auditing process was outsourced to Deloitte, an external audit institution which during this period carried out an extensive audit, covering also the process of delegating business trips and approving travelling expenses. Thus, one of the numerous auditing tasks in the examined organization was to take a look at the travelling expenses incurred in the organization in the previous year.

The objectives of the auditing task in the organization were to:

- assure that the conducted business trips and related expenses are in compliance with the internal guidelines of the organization,
- assure that the control mechanisms regarding delegating business trips and approving travelling expenses are sufficient and effective.

The organization is exposed to the risks identified in the auditing task according to the following categories:

- Improper issuance and approval of the business trip order,
- Improper settlement of travelling expenses,
- No accounting, formal and substantive control over the settlement of travel expenses.

The following example presents a simplified risk map consisting of four squares, illustrating the level of exposure to risk for the organization’s activities in respect of documenting the settlement of travel expenses. The risk map takes two parameters into consideration: the result (significance) and the probability of the occurrence of risk.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

Table 2. Risk map for the auditing task: Travelling expenses and the related costs in 2010 in the X unit

Name of the auditing task:	Travelling expenses and related costs in 2010.		File reference number 47
RISK MAP			
Significance/Result of risk:			
Probability of the occurrence of risk		Low	High
	low	1. Non-timely settlement of travelling expenses	2. Improper issuance and approval of the business trip order.
	high	3. No formal and procedural control when monitoring the business trip Improper settlement of travelling expenses	4. No accounting control during the settlement of the business trip No settlement of travelling expenses

Source: Drawn up basing on the unit's data.

Square 4 – essential risks, most important, threatening the accomplishment of organization's objectives, significant as far as the consequences and results are concerned, and the probability of their occurrence is considerable. They should be reduced or eliminated by means of applying preventive controls. Such controls should be the subject of assessment and examination.

Square 3 – significant risks, but the probability of their occurrence is lower. They should be cyclically monitored in order to make sure that they are properly managed by the organization and their probability of occurrence remains low. Detective controls should be applied in order to assure that the kinds of risk of high significance are detected before their consequences occur.

Square 2 – the kinds of risk in this square are of smaller significance but the probability of their occurrence is high. They should be monitored in order to assure that they are managed properly and that their significance doesn't increase during the changing operating conditions.

Square 1 – the kinds of risk in this square are not significant and the probability of their occurrence is low. They require minimal monitoring and control, unless the next risk assessment reveals that they have moved to a different category.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

The scope of examination included the review of the process from the acceptance of the business trip to the approval of the travelling expenses on the basis of the “Business Trip Order” documents of the examined unit and the expenses connected with the management board’s business trip. Basing on the received “Business Trip Order” documents (47 items) the auditors carried out the review regarding the functioning of the control mechanisms and the quality of the drawn up documents. The conducted examination did not involve the legitimacy and advisability of the business trip. The examination showed that the destinations, purpose of the trip, as well as the kind of transportation were specified in all of the examined documents of the Business Trip Order. The duration of the trip was specified in 45 out of 47 of the examined documents.

On the basis of the examined documents the auditors assessed the control mechanisms in respect of delegating / approving the management board’s business trip to be sufficient, however effective in 89% of all the documents.

The examination confirmed the business trips’ conformity regarding:

- The destination in all of the examined documents,
- The duration of the trip in 43 out of 47 documents,
- The kind of transportation in 42 out of 47 of the examined documents.

The examination showed that during the settlement of the business trip not all of the attached bills were included and accounted for in the Travel Cost Accounting. Those not included were accepted by the management board (except for three invoices attached to the Business Trip Order) on the so called “Document control” form attached to every bill.

On the basis of the performed audit the auditors assessed that the planned control mechanisms regarding the approval of the settlement of the business trips exist, but their appropriate application (signature and date) is insufficient, as it concerns 64% of the examined documents. On the other hand, the acceptance of the invoices attached to the business trip was identified in 96% out of 23 examined Business Trip Orders. Then the auditors assessed the paid allowances and expenses incurred during the business trip. The audit revealed the correctness of calculating the allowances in 21 out of 33 cases which constitutes 64% of all of the examined documents. In the auditors’ assessment the allowances for the time of delegating to the employee’s place of permanent or temporary stay and during the non-working days were calculated incorrectly. The incurred costs of the business trips, except for 7 invoices for the purchase of railway tickets (the invoices attached to the settlement of travel expenses do not contain infor-

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

mation about the date and itinerary), were incurred according to the date and destination specified in the Business Trip Order.

The auditors' attention was directed at the questioned invoice for the consumption during the non-working days. Therefore, basing on 47 examined documents the auditors assessed the control mechanisms in respect of carrying out the inspection of the business trips settlements from substantive, formal and accounting perspective to be sufficient, however not completely working. The examination confirmed carrying out substantive control in 13%, whereas formal and accounting control – in 60%. The identified irregularities concerned mainly the lack of approving the performance of substantive, formal and accounting control by signature and date on the Travel Cost Accounting documents, in spite of the requirement to do so.

The Audit Function confirmed that the process of delegating the business trips and approving the travelling expenses is effective, with the included control mechanisms, however not in every point. What constitutes the weakest links are the substantive, formal and accounting approvals, as well as the quality of the process documentation, which is satisfying only at some of the stages of creation. Most of the irregularities were the result of the qualitative non-refinement and lack of developed internal procedures concerning, among others, carrying out the inspection of the proper calculation of the allowances and the correctness of settlement of the travel expenses in the substantive, accounting and legal respect.

The conducted auditing examination confirmed that the internal rules (procedures) of delegating, accepting and accounting for the business trips are in compliance with the policies and the system functioning in the organization. The auditors paid particular attention to the identified invoice for consumption on a non-working day and the business trips that include the weekend stay of the delegated employee in the place of residence.

Recommendations which were issued after the performed audit were as follows:

- To improve the quality of the drawn up documentation,
- To properly and in writing carry out the substantive control of the Travel Cost Accounting,
- To properly and in writing carry out the formal and accounting control of the Travel Cost Accounting.

The information about the implemented recommendations was received by the Internal Audit Office and the management of the examined organization.

Conclusions

The presented discussion certainly does not exhaust the subject matter of the examined issue, it only brings closer – according to the authors' intend – the context of audit's role with reference to risk in the organization. The audit as the control tool constitutes a really significant protective instrument connected in the organization with the risk management process. In particular, the relation of the internal audit with the risk management results not only from the IIA's guidelines to be found in the audit's definition, but also from the increasing awareness that every business activity is exposed to risk. In order to reduce the risk exposure by means of applying a diligent audit, the risks should be first properly diagnosed, that is to say identified, during the integrated risk assessment. In this study the identification of risk was performed for the auditing task concerning the travelling expenses and related costs on the example of the risk map of the examined organization. Most generally speaking, in order to enable the implementation of the risk mitigation methods in the organization, an adequate control system and integrated risk management system have to be established. It is assumed that the internal audit is focused on the assessment of effectiveness of functioning of such risk management system and on the possibility of introducing changes and improvements. The audit begins with becoming familiar with the environment in which the organization operates and the risks connected with its activities, at the same time controlling the way the risk management system is designed and to what extent is it operationally effective.

Market or Government – Is There a Third Way?

JEL Classification: *A13; B00; P51*

Keywords: *Globalization; localization; market; planned economy*

Abstract: The paper deals with the discussion on the possible models of economy – market economy, which is usually associated with capitalism, and planned economy, which is usually associated with socialism. The experience of the 20th century has shown that efforts to choose the model of socialism have failed. Is it sufficient to make a conclusion, that capitalism is preferred to socialism not depending on conditions? Even if so, that the events of the 21st century show, that model of capitalism also has faced serious contra versions, and thus should be significantly modified. The great economists from Smith to Keynes have made forecasts about the new model of economy in the future – neither socialism, nor capitalism in a common sense. To solve the global problems, we need to think outside the box, revising critically the conventional wisdoms, thus creating a new model of economy. A possible way in that direction may be the localization of economy in a global scale.

Introduction

The aim of this paper is to discuss the benefits and shortcomings of the two economic systems – capitalism and socialism, and to look for a possible third form of economic model. Certainly market could not be contrasted with socialism and even more government with capitalism. Government is an integral part of any organized society. However the functions of government, at least theoretically, differ in the two discussed models of econ-

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

omy. The historical discussion mostly has generally led to conclusions, that any of the two systems has its benefits and shortcomings, and the historical process of development needs to adjust the existing economic model to the actual circumstances, and to look for improvements. The present world situation proves the necessity for that.

The first chapter deals with the historical development of understanding the concepts of capitalism and socialism, the phases of capitalist development, and the forecasts for the future development of the great economic thinkers Walras, Keynes, Schumpeter and others.

The second chapter recalls the historical discussion during the 20th century about the main theoretical problem of socialism – the possibility to set adequate prices for capital goods otherwise than in market.

The third chapter marks a new alternative, that may be considered either as an improvement of the existing capitalist model, or as a new, third economic model – local economies. The huge pressing problems of the present capitalist system in such a model should be several times smaller and therefore it will be much easier to accustom with them.

Methodology of the research

The methodology of the conclusion making is based on qualitative historical analysis and empirical evaluation of the standpoints of the scientific discussion. The paper is mainly library-based. The ideas of world famous economists are taken from their own books in a printed form or that can be found in Internet.

The analysis and conclusions have been approbated in several scientific conferences – annual European Society for the History of Economic Thought conferences in Prague, 2008, Amsterdam, 2010, annual Latvian Economic association conferences in Riga, 2010 and 2013, in the International conference of the Latvian Institute of Social Market Economy in Riga, 2012 and in the 7th International symposium of Warsaw University of Life Sciences in Jachranka, 2014. The main ideas have been discussed in the contents of study courses in BA School of Business and Finance in Riga, and have been developed in some previous publications, mentioned in the References. Author expresses special thanks to Professor Dzintra Atstaja (BA School of Business and Finance) for close and lasting cooperation discussing and developing the ideas and the results.

The Roots and Development of Two Modern Economic Systems

Since the XIX century mankind deals with two alternative models of economy – capitalism and socialism. Both these terms appeared in the middle of the XIX century. The term “capitalism” has its roots in Latin, based on “*caput*” – head, from which the term “*chattel*” was derived in a sense of a movable property. Such economists as David Ricardo and Pierre-Joseph Proudhon used term “*capitalist*” in their works; Karl Marx and Friedrich Engels were using term “*capitalistic system*”. The term “*capitalism*” in a modern sense came into our conversation language in the end of the XIX century, mainly due to German economists Werner Sombart, Max Weber and others.

The term “socialism” also has its roots in Latin – “*sociare*”, which means “*to share*”. The use of the word “socialism” in a modern sense is associated with the French philosophers and economists Pierre Leroux, Henri de Saint-Simon and others.

During the last two centuries there have been different definitions and interpretations of “capitalism” and “socialism”, thus creating the possibility of different interpretations of political and economical systems of various countries. Certainly, the ideological aspects constantly have led to confusion with the definitions of the two systems. In this paper the distinctions between capitalism and socialism are viewed in economic dimension. In that sense the main feature, that distinguish one model from the other is: in capitalism there is a private property on capital goods, in socialism capital goods are public domain. It follows that capital goods are not subject to the market, and thus the adequate price setting problem appears. Therefore it is necessary to have a centralized price setting institution, as well as a centralized institution, which will organize the process of resource distribution. From the point of view of economics, a public property of capital goods and centralized planning are the two main features of the socialism.

The roots of discussion about benefits and shortcomings of the both systems go back to ancient Greeks. Plato’s and Aristotle’s dissonant opinions may be interpreted as early roots of opposing these two systems, contrasting the fairness to utility, usefulness to efficiency, cooperation to competition. An exciting discussion about both systems, is given in the fundamental book of Leon Walras, where author associates these opinions with Plato and Aristotle.

“From the very beginning of human society and from the first appearance of social wealth, the problem of the distribution of this wealth has

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

been subject to debate. ... Of all the systems of distribution which have ever been devised, the two most prominent are communism and individualism, which have had as their respective champions the two greatest minds of antiquity, Plato and Aristotle. ... Communism says, "Goods ought to be appropriated collectively. Nature has given them to all men, not only to men living today but to posterity as well." ... In reply individualism argues. "Goods ought to be appropriated individually. Nature has made men unequal in virtue and talent." ... Which is right, communism or individualism? Are not both of them both right and wrong in the same time?" (Walras, 1874).

Except the fact that Walras uses term "communism" instead of "socialism" and "individualism" instead of "capitalism" the text of Walras seems very live issue in modern world. Indeed, the "communist" ideas, which Walras associates with Plato, are both right and wrong in the same time, as well as ideas of "individualism", which are associated with Aristotle. Walras is not judging who is right and who is wrong, but points out: "the theory of property must be in essence a moral science. ... If, therefore, any science espouses justice as its guiding principle, surely it must be the science of the distribution of social wealth, or, as we shall designate it, *social economics*."(Walras, 1874)

Socialist ideas have been likable to many people at all times and countries. The principle, that a person can acquire wealth not only by work, but also from interest on capital has been considered unjust. From the other hand such a possibility has been acting as powerful motivating factor. The idea that the most talented, clever and diligent members of society should be remunerated for that, also seems to be fair.

Up to the XVIII century the existing economic model was neither capitalistic nor socialistic in a modern sense, as there was private property on capital goods, but as it was mainly physical capital, there did not existed significant flows of capital in a global and even national level. The Industrial revolution with its retinues – capital concentration, financial markets, economic growth and globalization (the latter with a delay of hundred years) created the economic model, which we know as capitalism, and the theoretical basis of which is the fundamental work of Adam Smith "An Inquiry into the Nature and Causes of the Wealth of Nations", published in 1776, and being one of the signals of the new-coming era of capitalism.

The problem of globalization – why it was not a close satellite of development of capitalism in its first phase, but took its place only later - in the second phase, is thoroughly discussed in the paper of the famous Brazilian

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

economist Celso Monteiro Furtado: “It is known that during a first period, enterprises in the nations that headed the Industrial Revolution forced the opening of external markets, which explains the imperialist offensive that occurred throughout the 19th century. Nevertheless, the true motor of that economic growth was not so much the dynamism of exports, but instead the amplification of internal markets, derived from the increased buying power of the wage earning population. ...The explanation for this historical picture is found in the advance of new social forces, which appear at the same time as the process of urbanization generated by industrialization itself. The evolution of the system of power, a consequence of the action of organized workers, carried with it the elevation of real salaries and obliged governments to adopt protectionist policies to defend their respective internal markets. In this fashion, and starting at that moment, the motor for growth was the amplification of the internal market, with a subsidiary contribution from exports.” (Furtado, 1999)

None of the serious thinkers, including Marxians and Marx himself, deny the qualitative changes in the existence of mankind, brought by the new economic system. It created a new basis for human development, scientific discoveries, improvements in people everyday lives, changing the world beyond recognition. Though nothing in this world is only positive and negative, and the new economic system, with all its benefits, brought also new problems, at first increasing social inequality, which encouraged people to seek improvements to the existing system, or a new, better system. Therefore the forward-looking ideas of Walras about social economics as a science, which is investigating the principles of providence and usefulness in distribution of goods, are very up-to-date and will be even more important in the future.

The events of the 20th century seem to have proved the socialist system to be less efficient than the economy driven by the market forces, and put the discussion to an end. But the example of the Soviet Union shows, that capitalism is better than a bad socialism. From this one it cannot be concluded that a good capitalism is certainly better than a good socialism. The events of the 21st century both in a global and local scale show that existing capitalism system has a lot of heavy problems. Cambridge professor Ha-Joon Chang discusses them in his book “23 Things They Don’t Tell You about Capitalism”, among which one can mention the growing inequality both among nations and individuals inside the country, unjust principles of remuneration for different kinds of labor (laborers vs. managers, production vs. services, public sector vs. private sector), the problem of “impatient

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

capital” as a result of too high efficiency of financial markets. (Chang, 2010) This goes hand in hand with the sensational speech of Nicolas Sarkozy in the World Economic Forum, where he mentioned: “The crisis we are experiencing is not a crisis of capitalism. It is a crisis of the denaturing of capitalism – a crisis linked to loss of the values and references that have always been the foundation of capitalism. Capitalism has always been inseparable from a system of values, a conception of civilization, an idea of mankind. Purely financial capitalism is a distortion, and we have seen the risks it involves for the world economy. But anti-capitalism is a dead end that is even worse. We can only save capitalism by rebuilding it, by restoring its moral dimension. I know that this expression will call forth many questions.” (Sarkozy, 2010)

Perhaps, that is the reason for the necessity to reconsider the basic principles of the possible models of economy. Almost of the great economists – Smith, Ricardo, Mill, Walras (previously quoted), Keynes, Schumpeter have pointed the necessity to reconsider the economic paradigm in the future. For our generation it may turn out to be not future, but present. To justify this, let us quote the last public speech of Schumpeter: “Marx was wrong in his diagnosis of the manner in which capitalist society would break down; he was not wrong in the prediction that it would break down eventually. The Stagnationists are wrong in their diagnosis of the reasons why the capitalist process should stagnate; they may still turn out to be right in their prognosis that it will stagnate - with sufficient help from the public sector.”(Schumpeter, 1950)

Keynes is less pessimistic as Schumpeter, when he says: “I see us free, therefore, to return to some of the most sure and certain principles of religion and traditional virtue-that avarice is a vice, that the exaction of usury is a misdemeanour, and the love of money is detestable, that those walk most truly in the paths of virtue and sane wisdom who take least thought for the morrow. We shall once more value ends above means and prefer the good to the useful. We shall honour those who can teach us how to pluck the hour and the day virtuously and well, the delightful people who are capable of taking direct enjoyment in things, the lilies of the field who toil not, neither do they spin. But beware! The time for all this is not yet. For at least another hundred years we must pretend to ourselves and to every one that fair is foul and foul is fair; for foul is useful and fair is not. Avarice and usury and precaution must be our gods for a little longer still.” (Keynes, 1930)

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

Anyway one can make a conclusion, that the possible escape route is the restoring of the moral dimension. Is it possible in the global world, and what are the alternatives? These are questions that are waiting for immediate answers.

Socialist Calculation Debate

One of the fundamental discussions about the theoretical possibility of a socialist model of economy is the problem of price setting for capital goods. As calculations in the capitalist system are based on market prices, the impossibility of calculations is not a threat in this case. But what about socialism, where capital goods belong to the society and are not subjected to market? Indeed, is it possible to use successfully in decision making plans, containing measurements in a monetary form, if they are based on prices, that are not set in the market and thus not adequate?

The discussion about the possibilities and efficiency of price setting in capitalism and socialism started in the beginning of the 20th century. The Italian economist, the successor of the school of Lausanne and ideas of Leon Walras – Enrico Barone claimed that the setting of adequate system price in socialism can be done at least as successfully as in capitalism, because prices can be considered as the solution of the equation set of the Walrasian general equilibrium theory. (Barone, 1908)

The discussion was continued by the Austrian economist, a follower of Marxian ideas, Otto Neurath. He mentioned that during the World War I governments of many European countries were carrying out “war economy”, providing high employment and avoiding business cycles. The goal of the governments was not to maximize aggregate monetary indicators of volume, but to satisfy the needs of state and society. Therefore Neurath made a conclusion that such an economy operates more efficiently than a market economy, at least in wartime conditions. Can it be the same in a peace-time? Even before the war Neurath considered possibility to create an economic system, which could successfully function without money. After the war Neurath considered a model of economy, which would provide objective needs of the society according the “war economy” model, but that “additional benefits”, i.e. goods and services, which are outside the necessities, should be produced in another sector of economy, where money will be on the basis of exchange. (Neurath, 1919)

These ideas of Neurath correspond with the approach of the Latvian economist Karl Ballod, mentioned in his „Ein Blick in Der Zukunftsstaat”.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

(Ballod, 1898) Ballod considered that the main goal of economy is to satisfy the basic needs of the people, which can not be identified with people's desires. These needs can be calculated statistically. The economy of the country shall consist of two institutional sectors – public sector, which is not driven by the market forces, but acts as in the planned economy. The other – private sector deals with people's desires, and is driven by the market forces.

The ideas of Neurath were taken with enthusiasm by German socialists Otto Bauer and Emil Lederer, who did not support the opinion of Neurath about getting rid of money, but agreed with Neurath, that the decision making in socialism is more efficient than in capitalism. The discussion was developed by American economists Fred M.Taylor, Abba P.Lerner, Polish economist Oskar Lange and British economists Maurice H.Dobb and Henry Douglas Dickinson.

The most prominent opposite point of view, containing a fundamental criticism of socialism, is expressed by Austrian economist Ludwig von Mises. He attacked the basic concept, arguing, that any indicator, that is measured in monetary terms is baseless, because it is impossible to determine the price of any commodity without the market based price system. "Without calculation, economic activity is impossible. Since under Socialism economic calculation is impossible, under Socialism there can be no economic activity in our sense of the word." (Mises, 1920)

Oscar Lange offered a model for adequate price setting (Lange, 1938), later the model of adequate price setting was developed in the works of Leonid Kantorovich, "father" of Linear Programming, the only one of the Soviet Economists, who has received the Nobel Prize in Economics. The basic concept of Kantorovich was the notion of shadow prices, which show the price of a given resource at given prices of final products, i.e. marginal efficiencies of resources, and allows evaluating the costs of natural resources. In the end of the 30-ies orthodox Marxists considered the ideas of Kantorovich as an attack on the labor theory of value; therefore Kantorovich could publish his ideas only twenty years later, after the end of the Stalinism era. (Kantorovich, 1959) His disciple, Ivan Siroyezhin, developed these ideas. (Siroyezhin, 1980)

The response to the defenders of possibility to calculate adequate prices in socialism was given by the ideological successor of Mises, Friedrich Hayek, who argued, that the economic planner would need a terribly large amount of information to perform adequate calculations. Furthermore, there is no guarantee that individuals, who will take the decisions, will not be

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

influenced by selfish interests, and even if not, their motivation will be less, than it would be if they were making decisions about their own property. This was strengthened by American economist James Buchanan: “The more significant criticism of socialist economic organization lies in the difficulties of choice-making. Even if the socialist state should somehow discover an oracle that would allow all calculations to be made perfectly, even if all preference functions are revealed, and even if all production functions are known with certainty, efficiency in allocation will emerge only if the effective decision-makers are converted into economic eunuchs. Only if such men can be motivated to behave, to make decisions in accordance with cost criteria that are different from *their own*, can this decision-structure become workable.” (Buchanan, 1969)

Still, as one can see from the quote from Buchanan, in principle he does not deny the possibility of such calculations. The two problems, that for Hayek and Buchanan seem to be insolvable, are: 1) the problem of the terribly gigantic size of the model, 2) the problem of “economic eunuchs”, which hardly exist in the modern society. If these problems hypothetically could be solved in the future, there it may turn out a necessity to return to the socialist calculation debate. (Brivers, 2009)

Localization of Economy – is this a Third Way?

In present it becomes obvious, that the forecasts of the great economists are true, and more and more facts indicate the necessity to upgrade the capitalist model significantly or even to search for a new model. Financial innovations have spoiled the market mechanism. The innovative ideas in the speculative economy have destroyed the function of market economy, which equalizes the profitability of different businesses in a long run. Since the collapse of the Bretton Woods system, speculative economy has become more and more profitable, and the innovative ideas there have kept this profitability for more than 30 years, inhibiting investors and entrepreneurs from the real economy. Finally, the profitability of the speculative economy has collapsed with a blast. A possible alternate solution is to consider non-financial and financial capital separately. Non-financial capital is a private property, but financial capital – just the opposite, is only a public property. This item has been discussed in another paper of the author. (Brivers, 2014)

The way to find a new economic model, which is mainly based on a private property, being above all capitalistic, is the way of localization of

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

economy. The basic idea of small economies versus big economies may be based on the concept of Ernest Schumacher. “When we move from small-scale to medium-scale, the connection between ownership and work already becomes attenuated; private enterprise tends to become impersonal and also a significant social factor in the locality; it may even assume more than local significance. ... In small-scale enterprise, private ownership is natural, fruitful, and just. ... In large-scale enterprise, private ownership is a fiction for the purpose of enabling functionless owners to live parasitically on the labor of others. It is not only unjust but also an irrational element which distorts all relationships within the enterprise.” (Schumacher, 1973) In this quotation Schumacher considers mainly the micro level, but the same idea, contained in the title of the book – “Small is beautiful: Economics as if People Mattered”, is applicable to the macro level as well. Indeed, as it has been broadly discussed, the present form of economy is such, that people matter less and less giving preference to figures and money.

Every nation must be able to develop on its own, without help from outside. All vital products must be produced within its own country. Only in this case the state can be truly independent. Any country whose economy is dependent on other countries is not only vulnerable to crises, but also can become a victim of various types of extortion. And vice versa - a truly independent country can build healthy trade relations with other countries by exchanging the surplus of production and specific products, but maintaining economic independence and without being under the yoke of debt.

The main benefit of such independent national states will be the possibility to strengthen the society by re-establishing the virtues, which will be based on true human values.

Localization does not mean elimination of international trade. On no account it means any restrictions for people travelling and cooperation; just the opposite – it requires more and more cooperation in a global scale. In local economics the present problems of capitalistic model will take place, but in a far much lesser extent. As it has been said in the film of the English author – economist Helena Norberg-Hodge “The Economics of Happiness” – there is only one economy that has sense: it is local economy. We should localize our economic activities, our minds, our spirits. Not only “Buy local”, but also “Sell local” and “Act local” should be the basic principles of economy. At first we should stop the discrimination of the producers, who produce for the local market, avoiding direct and hidden subsidies for the exporters.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

The decision making in a local level in most cases will be more effective, as it moves closer to the performer. Local food, local energies, local banking – these are the routes for the movement to local economies. These ideas become more and more popular in the world. Perhaps it may be the basis of the new capitalist economic model, where people matter, and money, economic growth, innovations, etc. are means, not the ends.

Conclusions

The discussion about two possible economic models – capitalism, associated mainly with the power of market, and socialism, associated mainly with power of government, has been the item of discussions between philosophers, economists and politicians since ancient times. The events of the 20th century have shown that the capitalistic model of economy has turned out to be victorious over the socialistic model. From the main distinction between the two models - the private or public property of the capital there turns out the problem of adequate price setting for capital goods in socialism. The discussion about possibility to set adequate prices otherwise as in market continued for more than half a century, and came to a conclusion, that it is not realistic. Still from the point of view of future and, if the problem is considered in a small economy, as in local economies, the insurmountable obstacles may turn out to be much smaller, and it may be useful to return to that discussion.

One of the most influential economists of the 19th century Leon Walras, when discussing the shortcomings and benefits of each economic model, did not make a final judgment, which one is the best. His suggestion was to develop the social economics as one of the main branches of economic science. In modern world social economics should take much more important place in economic science, research and study programs in the universities.

The present problems of the capitalism have increased significantly and need an immediate solution. The possible alternative, that may be considered either the way, how to upgrade the existing capitalist model, or the way, how to create a new, third economic model, is localization – creating small, self-sufficient economies, that should widely cooperate, but keep their independence. Local needs should come first, and people activities, minds and spirits should be closer to home. Both in micro and macro levels, and even in a household level, true friendship requires that both sides are not dependant each from other. The best economic model is, where econo-

my no longer appears as an end itself, but as a means to an end, and the main goal of it is the happiness of the people – the economics of happiness.

**The Specific of Economic Competitiveness
Evaluation of Cities from Cross-border
Region Under the Context of Urban Shrinkage**

JEL Classification: *O11; O18; R11; R58*

Keywords: *city; cross-border region; economic competitiveness of cities; shrinking cities*

Abstract: This article analyzes the issues of economic competitiveness evaluation of cross-border cities under the context of urban shrinkage. Currently the "urban shrinkage" issue is on the top of the political agenda in Europe. Under the globalization conditions, especially cities, which suffer from urban shrinkage, have to find new and modern means and attitudes for increasing urban competitiveness. The absence of methodological tools for the evaluation of economic competitiveness of the cities of cross-border regions is becoming one of the obstacles that impede the real identification of the current situation and predicting perspectives of the cross-border urban development and competitiveness. The purpose of the article – to identify the challenges and factors for improvement of economic competitiveness of the cross-border cities under the context of urban shrinkage and to develop methodological guidelines for the evaluation of cross-border regional economic competitiveness based on the findings of analysis performed on Lithuanian-Polish cross-border cities. The article distinguishes basic characteristics of the shrinking cities and related problems that have a direct impact on the improvement of economic competitiveness of the city. The economic competitiveness evaluation methodology on the cross-border cities is developed and its practical applicability is verified, based on the sample of Lithuanian-Polish cities (Alytus, Marijampole

18-19 June 2015, Economics and Finance**

(Lithuania) and Elk, Bialystok (Poland). Panevezys and Siauliai are additionally added to the analysis as industrial cities located near Lithuania - Latvia border). Strategic recommendations on improving the economic competitiveness of Lithuanian-Polish cross-border cities are introduced in the context of urban shrinkage.

Introduction

This article analyzes the issues of economic competitiveness evaluation of cross-border cities under the context of urban shrinkage. Many cities, especially from countries of small economies, face with characteristics and consequences of urban shrinkage. The main problem regarding increasing competitiveness of shrinking cities relates to rethinking of their future competitiveness in the context of decline. Competitiveness and economic growth problems are particularly important and relevant to the cross-border cities, mostly because they are remote from the central regions of the country and the capital city (operation of the periphery syndrome), they are often economically 'distant' and having slower development trends. Scientists refer to various causes of such economic-social inequalities, determined by both nationwide and specific. However, the scientific literature and strategic European Union and individual countries' documents support the idea that the economic and social disparities both within the same country and between different countries must be reduced, and indicates that one of the ways to achieve this is to encourage economic co-operation between different cities. Various measures and forms to promote economic co-operation, employed by cities, companies, institutions or organizations of different countries, encourage the development of regular contacts and communication, which gradually evolve from an informal communication into a formal co-operation. In this way, the promotion of economic co-operation allows reducing the spatial isolation, influenced by national borders, and thus improves the economic competitiveness of individual cities. Thus, an active economic co-operation between cities of different countries can be a successful measure which allows to activate the socio-economic life of cities, particularly of those exposed to the population decrease related problems and consequences, successfully employ their development potential and turn them into centers of economic growth.

Both foreign, Lithuanian and Polish authors, very often analyze and evaluate the competitiveness of individual regions and cities, identify the factors that increase competitiveness and seek for ways and create various strategies to increase competitiveness. However, the scientific literature focuses mainly on the problems related to competitiveness of the national

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

towns or regions, without taking into account the specifics of cities of cross-border regions and the shrinking cities. The formation of common methodological framework for assessing the economic competitiveness of different countries' cross-border cities is impeded by the use of two countries' socio-economic development indicators, which in different countries are calculated in different ways and are based on different methodologies. The absence of methodological tools and guidelines for the evaluation of economic competitiveness of the cities of cross-border regions is becoming one of the obstacles that impede the real identification of the current situation and prediction of perspectives of the cross-border urban development, which is a prerequisite for an effective decision-making on the increase in the city's economic competitiveness.

The purpose of the article – identify the challenges and factors for improvement of economic competitiveness of the cross-border cities under the context of urban shrinkage and to develop methodological guidelines for the evaluation of cross-border regional economic competitiveness based on the findings of analysis performed on Lithuanian-Polish cross-border cities.

Methods of the research: systemic, comparative and logical scientific literature analysis; empirical research employing systemic analysis of external secondary data.

In this article an urban economic competitiveness is defined as an ability of a city to use various (economic, social, institutional, infrastructure, nature etc.) factors of competitiveness in order to make a competitive position and maintain it among other cities and be attractive for different urban resources and functions. Such viewpoint allows treating the urban competitiveness as a self reinforcing process, where present factors of competitiveness (inputs) create future factors of competitiveness (outputs) and after that outputs become inputs for a new cycle of competitiveness process. This issue is fundamental for strategic planning, as the process of improving urban competitiveness is a continual and cyclical. The strategic decisions should be based on the up to date results of the measurement of competitive position and potential of a city.

In this article the cross-border region is defined as the administrative territorial unit consisting of two or more neighboring countries' territories, which has its own identity and some common historical, cultural and socio-economic characteristics, but the authorities represent the needs of different countries and political-legal rules. The empirical application of the methodology of urban economic competitiveness evaluation by index is based on the evaluation of the specificity of these regions: Alytus and Marijampolė.

pole counties (Lithuania) and Warmian-Masurian and Podlaskie voivodeships (Poland).

The concept of shrinking cities and it's impact on urban competitiveness

Urban development is an ongoing cyclical process of change. During its history, every city may experience different development stages: growth, stagnation, decline or even death. Both internal and external factors affect the process and results of the development. This research focuses on the phenomenon of urban decline with particular attention to one of its type - urban shrinkage. Currently the "urban shrinkage" issue is on the top of the political agenda in Europe. The European Commission (2011) promotes the creation of diverse, cohesive and attractive cities that should be green and healthy, they should be places for a resilient and inclusive economy, yet the present reality in many European cities, especially in Eastern part of the European Union, shows the opposite situation and calls for immediate attention from local, national and European-level policy makers.

Shrinkage of urban areas is not a new phenomenon; cities underwent shrinkage processes throughout history. However, just around 1950 it became an important focus of concern and debate among policy-makers and researchers in many Western countries, especially in cities – former mining centers. While in the beginning urban shrinkage was mostly discussed within the context of industrial and rural regions, around 1990 decline processes became specific to all types of cities despite their size, status, history, functions or role in national urban systems. According to Oswalt and Rienitz (2006), in the beginning of XXI century, 25 percent of all cities (especially in former East Germany, most states of the former Soviet Union, even in the United Kingdom and France) with more than 100,000 population, were in decline.

Typically used in social and economic contexts, today the concept of 'shrinkage' is widely applied in the urban development context. In academic literature urban shrinkage is discussed using a number of similar terms: decline, decay, contraction, blight, crisis, disurbanization, etc. (Haase et al 2014). A general meaning of the word "to shrink" denotes "to contract", "to become smaller in size"; accordingly, "shrinkage" means "the amount by which anything decreases in size, value, weight, etc." (The Free Dictionary, 2015). Cities are dynamic open social-spatial systems, and the concept of shrinkage can be applied to cities as well. Local economic downturns, out-

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

migration (emigration, suburbanization) and demographic imbalances (negative birth rates) are main pre-conditions for decreasing in value, size, density or other physical and mental characteristics of a city. According to Hospers (2014), the development of urban shrinkage has different causes, but similar effects - “deterioration of the city's hardware, software and mindware¹”. However, Maheshwari (2013) pays attention to the opposite perspective towards the phenomenon: “shrinkage may not always be a bad thing. In the words of Aristotle: “A great city should not be confounded with a populous city.”

Salone, Besana (2015) identify urban shrinkage as “a phenomenon characterizing densely populated areas that record a population losing large sections of its extension and, at the same time, undergo a transformation of the economic base, presenting some symptoms of structural crisis”. Maheshwari (2013) provides the following definition: “a densely populated urban area with a minimum population of 10,000 residents that has faced population losses for more than two years and is undergoing economic transformations with some symptoms of a structural crisis.” Population loss is the most important element of both definitions, being both the cause and the result of negative urban transformation.

Researchers (Schlappa, Neill 2013, Martinez-Fernandez et al 2012) stress the role of globalization as a main driver for mobility of people across cities in search for more attractive places to live, work and/or entertain. While some communities are at the sending end (resulting in shrinkage of their population), other areas (e.g. capital cities, regional centres, vocational, academic cities) experience net gains. Shrinking cities typically face declining revenues, rising unemployment, outward migration of economically active population, rapid ageing, surplus buildings and land together with a physical infrastructure, which is oversized for the population it serves. Such cities lose former attractiveness to human (skilled, active labor force, students), capital (private and public sector investments) and other resources and functions (industrial, cultural, administrative, academic or other), necessary for smooth and successful urban functioning. It is important to note that shrinkage may happen at any level of the city: street, neighborhood, or district. Accordingly, the sooner and at the lower level this problem is detected and solved, the better and more sustainable results of the solution can be expected.

¹ According to Wang and Ouyang (2003), urban hardware is „technological innovation and integrative design”, software – „institutional reform and system optimization”, mindware – „behavioral inducement and capacity building”.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

In order to maintain a competitive position, the city should ensure its attractiveness to current and potential users of city's resources and functions (Sinkiene, Kromalcas 2010). Periodic performance of comprehensive diagnosis of the current stage of its development and attractiveness, provides a basis to foresee the trajectory of future development and to form the new strategic options in the context of shrinkage. Often, results of such analysis call for immediate action of city management. However, to know the problem is not enough; city managers must comprehend the causes and possible consequences of the problem. Most importantly, they must be aware of a wide set of strategies and tools to stop the negative development trends before they occur and to solve development problems in the most effective and timely way. A city has to devise policy directions to deal with the problematic situation.

How the process of urban shrinkage can be explained? What challenges does it create for local community? How to deal with urban shrinkage? What strategies and tools can be applied? These are the key questions that managers of cities in decline should raise and answer.

There are different possible solutions for cities, suffering from shrinkage, to adopt in order to stop or revert the negative spiral of development. However, there is no "one fits all" solution. As causes and context for shrinkage in individual cities differ, so are the solutions to tackle the problem. Governments of cities undergoing decline scenario can't simply shut off public services just because they aren't economical; all they can do instead is to target city investments where they will pay the greatest return to the quality of life of local population.

As literature analysis showed, cities across Europe chose different strategies to solve this problem; they range from preservation, greening, redevelopment, demolition, beautification, even neglect.

European Commission (2011) suggests a general direction for action: "Shrinking cities may have to redefine their economic basis and manage transitions towards new forms of economic, social and spatial organization". Strykiewicz (2014) also indicates more generalist strategies to deal with the urban shrinkage: counteracting or alleviating the adverse effects of shrinkage; seeking new sources of growth; promoting positive aspects of shrinkage.

Policies of German city Leipzig adopted around 2000 show the city's efforts to stop shrinkage by three priority areas of action: preservation of urban quality of the city centre; reduction of urban density through the creation of green or free spaces; improvement of competitiveness of the

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

city and its centres (Florentin 2010). The city also implemented the annexation of suburban cities aiming to “preserve the image of growth” and to get access to national funds (cities with a larger population have the right to receive larger funds from national support programmes).

Another example – a U.S. city Youngstown - after three decades of dealing with all typical negative effects of shrinkage, initiated its rebirth in 2010 by developing a new comprehensive plan with the overall vision acknowledging Youngstown's smaller size. This document provided the basis for implementation of different measures to manage the development of the city in a desired way. One of the measures – a special financial aid program - helped the city's government to focus on encouragement of residents to relocate out of neighborhoods that are too far gone to save, at the same time helping to stabilize transitional neighborhoods and keep healthy middle-class neighborhoods from wilting (Swope 2006). Other cities around Europe implement similar interventions – they demolish vacant housing stock and turn the plots into green spaces.

Liege (Belgium) city's strategy proposes to invest and densify around the infrastructural nodes (Dooghe 2005). Arts projects to change the atmosphere of the environment can serve as a useful tool to deal with shrinkage of individual city districts.

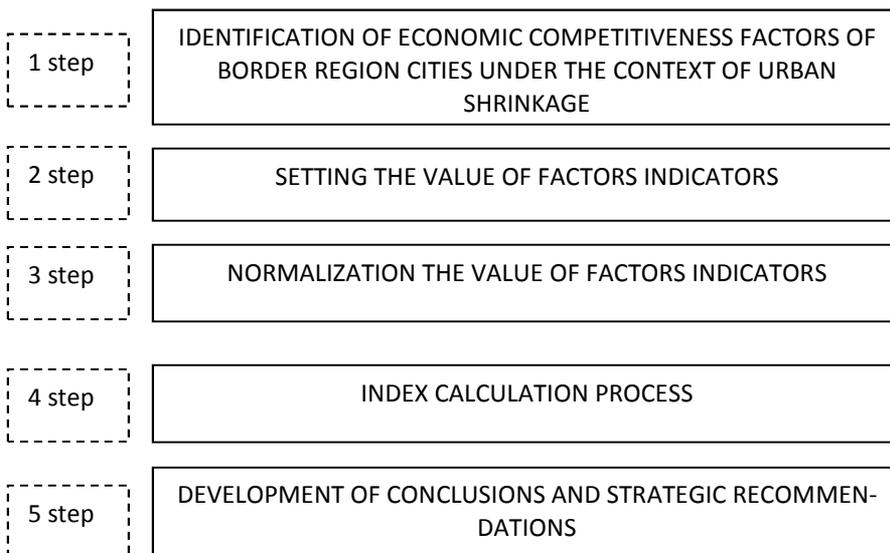

Different researches show that shrinkage is an urgent issue to many border cities. These processes became particularly evident in border cities of post-soviet countries soon after they implemented political, economic and social transformations. Economic restructuring, decentralization of power and responsibilities, free movement of resources created a completely new environment for development of border settlements. Some border cities, close to economically stronger neighboring country, grew; others - in contrast - faced with severe socio-economic and, often, environmental problems. The long-lasting stagnation encourage local population to move out; this is the first step to city's shrinkage. In order to control the development and to strive for growth, the city must periodically perform the analysis of economic competitiveness.

**The methodology of economic competitiveness evaluation by index for
the Lithuanian-Polish border region cities**

The scientific literature (WEF 2015, Ni et al. 2014, Huang, Hergül 2014, Ács et al. 2014, Bruneckienė et al. 2012, Snieška, Bruneckienė 2009) increasingly recommends to analyze a complex issue by index. Economic

competitiveness of the Lithuanian and Polish border region cities can be assessed not only by individual indicators but also by expanding the boundaries of this analysis and calculating the economic competitiveness index of the border region cities (UECI). The following index calculation stages can be distinguished (see Figure 1).

Figure 1. Index calculation stages

Source: own work.

In the first stage, the main economic competitiveness factors of border region cities are identified under the context of urban shrinkage. Implementation of this stage often employs the analysis of various scientific literature references, strategic documents and insights, economic trends and legal documents. During the second stage the values of factor indicators are defined. In the third stage these values are normalized, since various factors are expressed in different units and parameters. Normalization of variable values helps to avoid the predominance of extreme values and contributes to increasing the quality of the data. During the fourth stage the index calculation function is set and the index is calculated. Although the mathematical expression of the index may have an additive or functional expression, it is recommended to express the function in an additive expression. In the fifth stage, based on the calculation results, the conclusions are drawn and

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

policy recommendations for ensuring the increase in the city's economic competitiveness under the context of urban shrinkage are developed.

For the evaluation of economic competitiveness of the border region cities, the following cities of Lithuanian and Polish border region have been selected: Alytus, Marijampolė (Lithuania), Ełk and Białystok (Poland). For comparison, optional cities of Panevėžys and Šiauliai, as industrial cities near Lithuanian and Latvian border, were selected.

For the development of the economic competitiveness evaluation methodology for the Lithuania-Poland border region cities, first of all, a system of economic competitiveness factors was formed, consisting of 4 groups of factors and 13 factors (see Table 1). 19 indicators were selected to describe these factors.

Table 1. Conceptual system of economic competitiveness factors

Group of factors	Factor	Indicator
Competitiveness of companies	Economic activeness of companies	Number of economic entities per 1000 population Number of operating companies with the income of 14480 - 28961 Eur. per 10 000 population Paid and included in municipal budgets taxes
	Efficiency of companies	Value added created by employee, working in manufacture sector The ratio of GDP created by region's enterprises in compare to the country's GDP
	Openness of companies	Revenue from export per capita
Attractiveness of the city	Investment attractiveness	Material investments per capita Foreign direct investment per capita
	Awareness of the city	Accommodated guests in accommodation facilities per 1000 population
	Science infrastructure	The number of college students per 1000 population

In order to statistically significantly assess economic competitiveness of different cities, it is important to analyze it by a unified system of indicators. It should be noted that the main problem in selecting the indicators which represent economic competitiveness of the border region cities - limited possibilities to retrieve the same official statistics data from different countries (Lithuania and Poland), (especially at the urban level), as well as differences in methodologies for calculating the same data between the countries. Before selecting a unified system of indicators for the evaluation of competitiveness of the Lithuanian and Polish border region cities, the possibilities of obtaining such indicators in Lithuania and Poland were compared and a reduced unified system of indicators, describing economic competitiveness of the Lithuania and Poland border region cities, was formed, consisting of 4 groups of factors, 7 factors and 8 indicators (See Table 2).

All factors were given the same weight coefficient. The data were normalized by the standard deviation from the average method. The period of 2008-2013 years was selected for analysis. This time is sufficient to fully reflect the dynamics of economic competitiveness and its factors and analyze the reasons for this dynamics.

Table 2. Indicators for the evaluation of economic competitiveness of the Lithuanian and Polish border region cities

Group of factors	Factor	Indicator
Competitiveness of companies	Economic activeness of companies	Number of operating economic entities per 1000 population.
Attractiveness of the city	Investment attractiveness	Material investments per capita
	Awareness of the city	Accommodated guests in accommodation facilities per 1000 population
Labour market adjustment to the changing conditions	Job attractiveness	Number of the registered unemployed and working-age population The average monthly gross

Some indicators (e.g. direct foreign investment, capital investments, the indicators related to GDP) were only available in 2012; that is why for the assessment of the year 2012 and 2013, the same indicators were used, i.e. for the assessment of the year 2013, the indicators of 2012 were applied.

Results of empirical research

The dynamics of economic competitiveness index of Lithuanian and Polish cities during the period of 2008 – 2013 varied by different cities (see Figure 1). During the whole period of analysis, first places were taken by Polish cities – Bialystok and Ełk, making a large gap from Lithuanian cities by economic competitiveness. In 2008 Ełk UECI slightly exceeded Šiauliai UECI, but in 2009 and 2010 the economic development has gained a strong rate of growth, thus increasing the economic gap from Lithuanian cities. Meanwhile, the global financial crisis has strongly affected Lithuanian cities and their UECI, in contrast to the Polish cities, fell sharply in 2009 – 2010. During the whole period of analysis, the border region cities from the Lithuanian side – Marijampolė and Alytus - took the lowest position among the cities analyzed.

Economic competitiveness index by factor groups in compare to most and less competitive cities in 2013 is presented in figure 2. Elk is presented in blue, Alytus - in red.

Figure 2. Economic competitiveness index by factor groups in 2013

Source: own work.

During the whole period of analysis, the economic activeness of Alytus' enterprises was relatively low, ranked in the fifth position, leaving behind

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

only the enterprises of Marijampolė, which in 2008 - 2013 ranked in the sixth position. The most competitive enterprises were in the cities of Poland - Bialystok (first place) and Ełk (second place). Analyzing the attractiveness of the city components, it can be said that the UECI analysis only verifies that border cities are characterized by a low investment attractiveness and awareness. During the whole period under analysis, the awareness of Alytus was the lowest, compared to the other cities, and was positioned in the sixth place, while the investment attractiveness (only with respect to material investments) - the fourth or third place.

Similar problems were encountered by the Polish city of Ełk. The highest population density was noted in the cities of Bialystok and Ełk, ranking in the leading positions according to the local market demand scale during the whole period of analysis. By the population density, Alytus took the fourth position in the period under analysis, leaving behind Marijampolė (sixth place) and Šiauliai (fifth place). This indicator reveals that the Polish urban market is bigger, which suggests the relevance of international economic cooperation, especially from the side of Lithuanian cities. Wide was the range of variation in the position of Alytus by labor market adjustment to the changing conditions: in 2008 it took the first place, in 2009 - 2011 – the third place, and in 2012 - 2013 – taking the fifth position. According to the age structure of population and migration, during the whole period of analysis, Alytus city took the first place (Panevėžys - in the lowest position, while Bialystok and Ełk – respectively in the third and fourth position), whereas by the attractiveness of jobs Alytus ranked in the lowest position (in 2009, 2011 – 2013 - the sixth place), which also led to a low Alytus city's position in labor market adjustment to the changing conditions. Alytus was characterized by the highest levels of unemployment and the average (with respect to all cities analyzed) gross salary paid (by this indicator Alytus ranked in the fourth position). The most attractive jobs were identified in the cities of Bialystok, Šiauliai and Ełk with the highest salaries paid.

The scientific literature (Bruneckienė et. al, 2012) includes indications that in order to assess urban competitiveness, similar cities should be compared. Given the recent methodological recommendation and the data presented in Figure 1 and 2, the following groups of cities – competitors shall be distinguished: group of Bialystok, Šiauliai, Panevėžys and group of Ełk, Alytus and Marijampolė. In order to identify the specificity of economic competitiveness of cities located closest to the Polish - Lithuanian border,

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

the competitive strengths and weaknesses of the latter cities are identified, compared to Białystok, Šiauliai and Panevėžys (see Table 3).

The economic competitiveness research revealed that one of the decisive reasons for a low position of the border region cities among other cities is a low investment attractiveness and insufficient business conditions which facilitate a competitive urban business development, leading to a diminished economic well-being not only for individual residents, but for the whole city as well. Modern companies have realized that their own economic goals and corporate competitiveness is directly related to the city's economic and social well-being and progress. Therefore, business leaders are increasingly developing their competitive market strategies based on the shared value concept, when the company's competitiveness is combined with the city's development. Only the company's strategic actions which are focused not only on improving competitiveness of the company, but also on the development of the city's well-being, in a long term perspective ensure and bring benefit from the city's prosperity to the company itself. Thus, the implementation of the total value principles within the urban economic value creation process would ensure economic competitiveness of both the companies and the city, and this is becoming a mandatory condition for ensuring urban economic growth. Thus, an active cooperation between municipalities, entrepreneurs and young people has become not an issue of fashion, but rather the necessity and an essential condition for maintaining competitiveness and increasing the welfare of the city. Moreover, international economic cooperation undoubtedly benefits to both cities of different countries, therefore the establishment, development and maintenance of economic relations is an important, and for the border region cities – an essential prerequisite for increasing its competitiveness and welfare, especially under the context of urban shrinkage.

Table 3. Strengths and weaknesses of Ełk, Alytus and Marijampolė in 2013, compared to Białystok, Šiauliai and Panevėžys

Strengths	Weaknesses
Created conditions for the education and business partnership: developed science and education infrastructure	Weak and decreasing purchasing power of the local market: a decreasing local market demand (increasing number of people who face economic difficulties) and the level of material well-being.
Sufficient labor supply: a large proportion of the population of working age	Low productivity of companies
Relatively low labor drain, posing no threat to the staff turnover: a relatively small emigration	Insufficient economic relationship with foreign markets

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

The city municipality's promotion of investment	Low investment attractiveness and awareness of the city
An operating business support system in the city municipality, promotion of the average and small business	Insufficiently efficiently functioning labor market: too small number of jobs against the city's potential labor force (high unemployment), lack of skilled labor
Promotion of youth employment	Lack of entrepreneurs, enabling to bring economic breakthrough, new approaches and ideas to the city

Source: own work.

Conclusions

Caused by different yet interconnected processes of globalization, demographic change, outmigration, uneven economic development, suburbanization and other, in the decade urban shrinkage has become an unwanted development scenario for a growing number of cities around the world. Shrinkage is a particularly frequent scenario of cities located close to the national border and distant from main national centers of power and economy.

Urban shrinkage can be explained as a manifestation of city's population loss, high unemployment rate, industrial decline, degradation of built environment. The shrinkage processes can and must be managed in order to prevent from occurrence of even more severe social-economic-environmental problems within the area, which in turn may negatively affect the socio-economic development and competitiveness of the surrounding region or even nation.

An active economic and social cooperation between different countries' border regions can be a successful tool to activate the socio-economic life in these regions, successfully exploit the potential of the border region and turn the region into a center of economic growth. This can promote not only regional cohesion, but also contribute to the overall national economic growth.

The selection of economic competitiveness assessment methodology for the border region cities is significantly affected by their availability at the Lithuanian and Polish cities level and the differences of the same data calculation methodologies between countries.

In the economic competitiveness assessment methodology for the Lithuanian and Polish border region cities, introduced by the authors, the factors are grouped into four categories: corporate competitiveness, attractiveness

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

of the city, the labor market adjustment to the changing conditions and the purchasing power of the local market.

The empirical research has proved that the developed economic competitiveness evaluation methodology can be actually used as a tool for economic analysis at the regional level, distinguishing individual cities' competitive strengths and weaknesses, evaluating the dynamics of change in the urban economic competitiveness from the time and competitors perspective, and as a strategic planning tool for justifying and making strategic decisions on the improvement of regional or urban competitiveness. In addition, the methodology can be used as a tool for information and promotion of the city's economic competitiveness, as well as the quality of life, conditions for business and operational efficiency of public authorities.

Under the globalization conditions, especially cities, which suffer from urban shrinkage, have to find new and modern means and attitudes for increasing urban competitiveness. The researches proved, that the increase of economic cooperation among different cities and the incorporation of shared value concept into cities and companies development strategy may increase the economic competitiveness of cities and make it more attractive for different target groups.

**The Influence of Clusters on Economic
Development. A Comparative Analysis of
Cluster Policy in the European Union
and Japan***

JEL Classification: *F631; O12; O57*

Keywords: *cluster; effectiveness of clusters; regional development; value of regions*

Abstract: The development of clusters seems to be a natural consequence of the observed trends in the global economy. The increased interest in the creation and development of clusters can also be seen in most of the countries of the European Union, however, the experience of EU countries in this field is different. In addition to strong clusters with a long tradition, new clusters are created with much lower potential. Clusters compatible with the most important EU documents are to play the role of organizations supporting regional development and ensuring the growth of innovation of the European Union in the new programming period. Japanese economy is based on the important role of clusters in this area, which along with the US and the European Union is among the largest economies in the world. The experience of Japan in this area is much longer. A lot of still functioning clusters were created in this country in the XVII and XVIII centuries. The aim of this

* The paper is a part of the research project, which is being financed by the National Science Centre in Poland granted on the basis of the decisions number DEC-2013/09/B/HS4/01260.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

study is a comparative analysis of the socio-economic situation of the European Union and Japan, with special emphasis on the role, that clusters play in those economies. The result of the analysis is to identify the factors that allow for the effective operation of enterprises within created cluster structures. The analysis of Japan's experience in this area is a valuable source of information for policy guidelines developed to support clusters in the EU.

Introduction

In many countries, both in Europe and on other continents, an increased interest in economic policy has been observed in recent years, based on the concept of creation and development of clusters. In the case of Europe, this is largely due to the effect of Lisbon strategy having been implemented since 2000, whose main goal was to make Europe the most competitive and rapidly evolving, knowledge-based part of the world. Measures, that should lead to the economic growth as a result of the growth of innovation and competitiveness of the regions (thanks to regional specialization) are continued in the next strategic for the European Union document entitled Europe 2020 Strategy. This document implies the need for so-called smart specialization of regions. The strategy of smart specialization (RIS3) is defined as a national or regional innovation strategy, whose main goal is to build a competitive advantage due to the development of research and innovation capacity. This strategy also emphasizes the important role of clusters in the process of defining and developing smart specialization. It also assumed the need to develop significant clusters by exploiting the benefits of agglomeration, the scale and scope of local external benefits resulting from the production and distribution of knowledge (Europa 2020). Clusters also play an important role in the economies outside Europe. Interesting examples are clusters developing in Japan, which is regarded as the third economy in the world (after the United States and the European Union), particularly in the context of the applicability of the methods and techniques of Japanese supply chain management in other countries to which they are transposed (Witkowski, 2010).

The aim of this study is a comparative analysis of the socio-economic situation of the European Union and Japan, with a special emphasis on the role that clusters play in those economies. The analyzes were based on data available from Eurostat, the European Cluster Observatory, public statistical data of Japan and databases JETRO. The result of the analysis is to identify the factors that allow for the effective operation of enterprises in the created cluster structures. The experience of Japan in this area is a valuable source of information for policy guidelines developed to support clusters in the EU.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

This paper is organized as follows: the first part comprises of a general literature review of the concepts and theories on the clustering phenomenon and presents the place of this concept in new theory of value of the region. The paper presents the proposal of the examination procedure concerning the identification of factors determining the effectiveness of the clusters and the possibility to identify interdependencies that occur between these factors. The second part looks at contemporary research work and focuses on some indicators describing clusters. Finally, the relevant conclusions are drawn.

Theoretical background

Considerations for clusters fit in at least some areas of research, such as: economic policy, economic geography and regional economics. Within these areas, in the context of clusters such issues are discussed, e.g.:

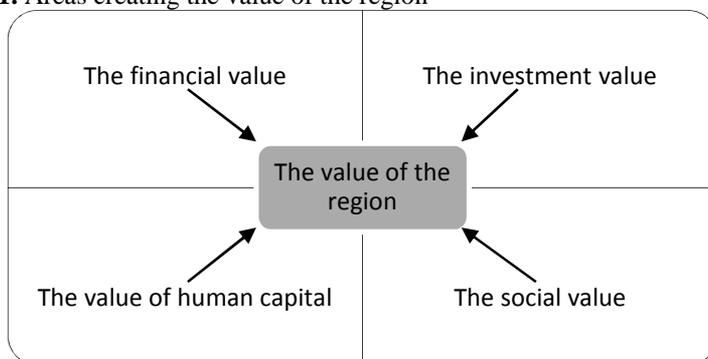

- the impact of clusters on the competitiveness of the economy, the development of regions (local development) and sustainable development (Andersson et al., 2004), (Gugler and Brunner, 2007);
- clusters and innovation and the creation and transfer of new technologies (Eisen et al. 1996), (Final Report, 2003), (Innovating Regions..., 2005);
- the place of clusters in the internationalization and development of entrepreneurship, primarily small and medium-sized enterprises (Frenken et al., 2010);
- the role of clusters in creating knowledge-based economy (Szymoniuk, 2003), (Kuah, 2002);
- the trends of supporting the clusters in cluster-based policy (Pilarska, 2010), (Solvell, 2009).

Relatively new is also a concept: value of the region, in which clusters play an important role. It is based on a new approach proposed by Michael Porter and Mark Kramer in 2006. In this conception, the authors indicated the need of transition from the traditional idea of corporate social responsibility (CSR) to Creating Shared Value (CSV) – a concept geared to attempting to solve a variety of societal issues from a business perspective – and consider what significance efforts by enterprises to implement CSV might have. Creating Shared Value is a management framework meant to reconcile the social value and the enterprise value that are generated from solving societal issues through an enterprise's business activities. The concept of "shared value" in Porter's thinking may be defined as policies and practices meant to improve the local community and economic environment in which an enterprise operates while improving that enterprise's own

competitiveness. Porter advocates an approach in which social value is created by addressing social problems and needs, the result of which will be the creation of economic value. The CSV concept entails three approaches: reconceiving products and markets, redefining productivity in the value chain, and creating industrial clusters to support the region in which the enterprise is located (Porter and Kramer, 2011).

The concept of value of the region was based on that which is „...the sum of the various values produced by the region (including the financial, investment, social and human capital) (...), which created the potential of the region, on which its development may be based on...” (Jabłoński and Jabłoński, 2012).

Figure 1. Areas creating the value of the region

Source: own elaborations based on Jabłoński A., & Jabłoński M. (2012).

The financial value in accordance with this concept, apart from the value of the budget, includes the value of the resources which is equity. The value of an investment, primarily understood as the ability to attract external investors, also takes into account the value of own investment. The social value includes the ability to create relationships and cooperation. The value of human capital in the simplest terms is interpreted as competence potential of residents of the region allowing primarily finding a good job. The value of human capital is also, especially in the western economies, its corresponding structure (described e.g. the number of births, the relation of population in pre-production, production and post-production age etc.). Described in this way the value of the region is a multidimensional concept, with its important ability to create a competitive advantage based on the interacting entities (understood as different groups of stakeholders, e.g., the business sector and the public administration sector). One form of such

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

cooperation, particularly in relation to small and medium-sized enterprises, are clusters.

Although the functioning of enterprises in the form of clusters is not new, in recent years this form of cooperation between enterprises is once again the subject of numerous studies and considerations (Gugler and Brunner, 2007), (McDonald et al. 2007), (Hegedus, 2008), (Porter and Kramer, 2011).

Clusters, usually, are defined as a geographical agglomeration of competing and related industries; and where there is evidence of improved performance such as a growth and profitability arising from the agglomeration of firms in a region (Porter, 2000, p. 248). Entities forming the cluster function in the value chain, which means having a certain specialization by them or business profile associated with the final product or service. The cluster can therefore create an entities representing various sectors, which are interrelated and complementary. According to the concept of EU smart specialization, clusters operating in the areas of smart specialization of regions are factors improving the competitiveness of such regions. External factors are more rarely considered. This could include endogenous potential of the region in which the cluster operates.

However, these factors largely determine the efficiency of the clusters. They should also be considered in the development of guidelines for cluster-based policy, understood as „...a set of different types of policies encouraging the development of regional systems of business organizations in the form of clusters ...”. This concept includes:

- indicated by Ch. Ketels (2004) all the efforts and the efforts taken by the government on its own and in cooperation with companies or e.g. research units focused on the development of clusters and competitiveness;
- proposed by OECD (2002) the definition according to which it is a set of actions taken by public authorities in order to stimulate the links between the companies making up the value chain;
- proposed by the IBnGR (2008) set of activities and instruments used by the authorities at various levels in order to stimulate the economy by creating new clusters.

These factors are also considered separately, while the effectiveness of the clusters is dependent on a set of mutual configured variables describing both factors directly related to the cluster as well as external factors, including the environment in which clusters operate.

Methodology of the research

The research procedure presented below is a proposal for an approach to the problem of identifying the factors determining the effectiveness of the clusters. This procedure refers to the global research, whose objective is to identify factors that improve or determining the effectiveness of the clusters.

The effectiveness is understood here as the ability to create a competitive advantage for companies functioning within the cluster either directly considered in relation to these entities and countries (regions) in which clusters exist. Below the stages of the research procedure proposed are presented in synthetically way. It should be noted that the study focuses on the first three stages of this procedure. Phases IV and V require identifying the factors, that may affect the effectiveness of the clusters. The present study focuses primarily on the identification of areas in which these factors can be identified.

Stage I. The development of methodological foundations of research, including: the identification of the factors determining the effectiveness of the clusters.

STAGE II. The identification based on literature review and own research of possibility to obtain data describing the factors affecting the effectiveness of the clusters.

STAGE III. Statistical analysis of selected factors determining the effectiveness of the clusters.

STAGE IV. The construction of models describing the relationship between the identified groups of factors and the effectiveness of clusters.

The proposed test procedure involves an integrated approach to assess the relationship between the identified groups of factors and the effectiveness of clusters using multivariate methods for classification and data analysis. To identify the factors determining the effectiveness of the clusters and of relations between them the following methods will be used:

- correspondence analysis, as a factor method allows the identification of relationships between variables and objects mainly in a graphical form, (Andersen, 1997), (Panek, 2010).
- factor analysis, which is used to describe variability among observed, correlated variables in terms of a potentially lower number of unobserved variables called factors. The main benefits of factor analysis are that the analyst can focus their attention on the unique core elements instead of

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

the redundant attributes, and as a data pre-processor for regression models (Sagan, 1998), (Bollen et al., 2009).

Recommended methods will make the identification of factors determining the effectiveness of the clusters and the interrelationships between them possible.

Factors determining the effectiveness of the clusters

Clusters are perceived as the source of a lot of advantages for the entities functioning in their structures and the countries in which they are located. Hence their significant impact on the value of region. Considering the direct benefits for enterprises functioning in clusters more and more attention is drawn to the diminishing role of factors such as e.g. an access to cheaper raw materials for the benefit of: the possibility of using a flexible division of work, an access to information and the ability to use scientific achievements and collaboration with research centers (SMEA, 2006).

However, the benefits for the countries in which clusters are located are: the development of innovation and new technology which turns into economic growth and greater competitiveness (Hegedeus, 2008, p. 81), the increase of attractiveness for foreign direct investment (Gugler nad Brunner, 2007), a positive impact on the labor market (Innovation Clusters, 2007, p. 10) and the strengthening of social capital (Boekholt and Thuriaux, 1999).

These benefits, which are part of the main objectives of regional policy concerning the strengthening of the competitiveness of regions cause, that public authorities are more and more interested in getting involved in the creation and development of clusters (Bochańczyk-Kupka, 2014).

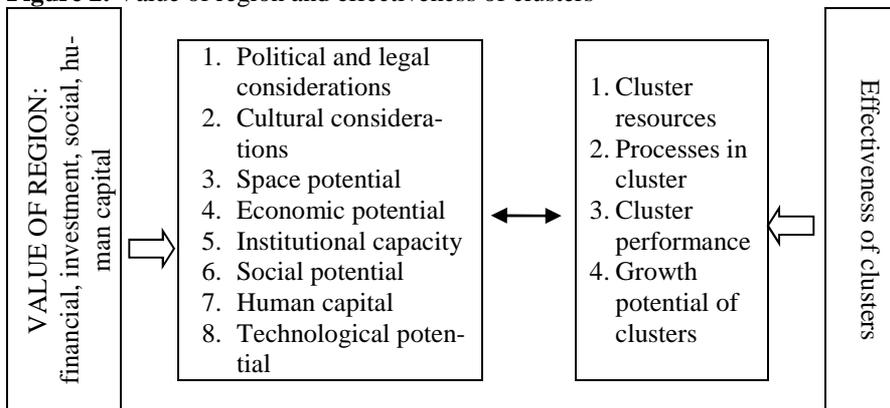

The effectiveness of clusters is conditioned by a number of factors. These factors are both relevant from the point of view of regions in which clusters operate and enterprises operating in clusters.

The value of the region considered from the perspective of financial, investment, social value or human capital includes factors as: political and legal determinants, cultural, its space potential, economic potential or social and technological potential. This value determines directly the potential of clusters operating in the region.

On the other side, clusters due to using the potential of the regions in which they function can maximize this potential, improve it, e.g. thanks to the introduction of new technologies or stimulating the development of human capital. Between these two areas mutual relations take place. The value of region determines the potential of clusters, so it has an impact on re-

sources, processes, results and the growth of potential clusters. However, the processes taking place in clusters affect the value of the region. It can be represented as follows:

Figure 2. Value of region and effectiveness of clusters

Sources: own elaborated.

The collaboration of businesses takes place in more and more turbulent environment around new technologies, whose effects are not known at the time of implementing them on the market. Therefore it is difficult to anticipate the directions of development of this type of markets. In addition, a company needs to cooperate more comprehensively requiring new skills as network management, technology transfer or more importantly the ability of acquisition, processing and exchange of information. In spite of better resource management skills and processes taking place in clusters, changes in circumstances occurring around clusters are in some economies very disturbing and have strong impact on the functioning of the clusters.

A good example of how the changes in the environment of clusters contribute to their operation is e.g. Japan. Changes in the environment of clusters in Japan and in its structure and the organization of clusters show that the factors determining the efficiency of clusters should be considered in a wider context, not only in relation to clusters themselves, but also taking into account the environment in which clusters operate.

**The role of clusters in the development of the Japanese
economy – implications for the European Union**

Although the Japanese economy, characterized by high efficiency, competitiveness and technological advancement, is considered to be the third economy in the world (after the United States and the European Union), for over 20 years has been in a state of economic stagnation. Particularly important in its case are demographic problems associated with an aging population, low rate of female fertility or errors in macroeconomic policy. Changes in this area generally concern all areas forming the value of region and consequently the effectiveness of clusters. From the viewpoint of the European Union they are also very important (Bossak, 2010).

In recent years there have been more and more opinions indicating that the demographic processes in the EU are largely a reflection of changes taking place in Japan. Although the number of people EU-28 has increased for over the last 50 years, particularly worrisome are changes of a structure according to the age of the population of the European Union. According to Eurostat data at the beginning of 2013 the population of the EU-28 was 505,7 million and it was almost 100 million more compared to the aggregate number of the population in the EU-28 in 1960.

In spite of this growth, the increase in a load factor of the population of working age by population in the retirement age is observed, which on 1st January 2013 was 27,5 for the EU-28 and was more than 3% higher compared to 2002. In addition, further aging of the European population is anticipated within next 35 years and the proportion of the population aged at least 65 years of age with 18,22% at the beginning of 2013 to 28,1% by the year 2050 (Eurostat, 2014).

However, in the case of Japan, the load factor of the population in the working age by population in the retirement age was at the beginning of 2013 more than 40,0%, and is foreseen to continue to grow in the coming years. This means progressive aging of the population.

An analysis of the growth rate of the population aged 65 or more and an increase in the share of this group in the total population indicates an intensification of demographic aging in both Japan and the European Union.

In Japan in the official statistical studies it is noted that „... Japan has become the first country to reach the status of “super-aged society...” (White paper, 2014). In addition, since 2011 trends have been observed that are related to the depopulation of the population, resulting in a decrease in both the number of births and the changes associated with migration trends.

Source: own elaborated on the basis of Eurostat data and public statistical data in Japan.

Japan particularly hard was affected by the crisis of the 2011 connected with the earthquake. This was another after the period 2007-2008, a period of decline in GDP growth. As a result of the earthquake and tsunami 656 private enterprises employing 10 757 people announced bankruptcy within one year. Although in the area of the earthquake only 12% of companies were located, the cause of the collapse of the rest were mainly disturbances in the continuity of supply (Ono and Ishiwatari, 2012).

Unfavorable for Japan socio-economic trends in addition to already indicated: population decline, low birth rate and aging population are also:

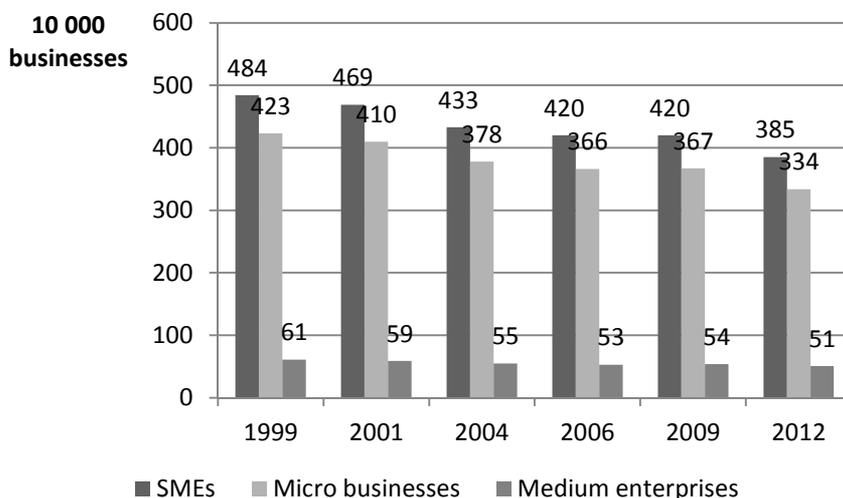

- The low rate of growth of GDP (while in the second half of 2013 there was an increase of 1,5% compared to a decline of 0,4% in the euro area). The main causes of GDP growth compared to the previous year in Japan were: an increase in private consumption and investment expenditure associated with declared changes in fiscal and monetary policy within the new strategy of the government (a program of three arrows). It is predicted, however, that the rate of growth in the coming years may be much lower.
- The withdrawal of investment funds from the Japanese market which shows the decline in the attractiveness of the market for investors.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

- The increase in investment of large Japanese companies in foreign markets causing a decline in orders for small and medium-sized enterprises that are subcontractors of large companies (White paper, 2006).
- The employment growth in the service sector and a decline in the manufacturing sector.
- A very large decrease in the number of micro-enterprises operating in the Japanese market caused both by a decline in demand and the migration of large enterprises beyond Japan.

Japan is going economic and social changes, that are making the management environment more challenging for small and medium enterprises (SMEs) and micro-businesses. The number of SMEs is declining long-term and it could drop further and speed the decline of regional economies.

Figure 3. Trends in number of SMEs in Japan

Sources: Recompiled from MIC, *Establishment and Enterprise Census, 2009 Economic Census for Business Frame*; MIC, METI, *2012 Economic Census for Business Activity*.

Micro businesses are very important to the Japanese economy, as they account for about 87% of all enterprises in the nations well as about 26% of all workers. The number of micro businesses is falling sharply as Japan's economic and social structure changes. Over the three-year period from 2009 to 2012, there was a decline of about 350 000 SMEs, among them about 320 000 micro businesses (of which 250,000 were sole proprietorships). In terms of percentage, there was a 4,8% decline in medium enterprises and

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

8,8% decline in micro businesses. There are now concerns that regional economic vitality will be lost with the market withdrawal of SMEs and micro-businesses, which have been important to regional economic growth.

The reduction in the number of enterprises is also reflected in the efficiency of the clusters. Currently in Japan there are over 2 million of private companies, of which only 5 thousand are large companies such as Sony, Panasonic, Toyota and Mitsubishi. The largest companies generate 50% of GDP and employs 20% of the workforce (White paper, 2012).

Many Japanese companies are operating in so-called a manufacturing vertical system. These companies employ many subcontractors which are often small companies employing housewives. This means that if you need an immediate reduction of production (it is not taken into account as a rule previously agreed terms of the contract), it is followed by a prompt reduction in staff, mainly women. According to experts of the Japanese market it causes a significant underestimation of the level of unemployment.

The current development of Japan is mainly based on innovation and new technologies. An export of goods has been replaced for 10 years with the growth in the export of capital and technology. Japan is ahead in this respect of the leading European countries: Germany, Britain and France, but the export is lower than in the United States.

Another important factor in the performance of clusters is their specialization. According to the Small and Medium Enterprises Agency in Japan in the late 90s of the twentieth century there were more than 530 substantially different clusters representing the following industries: processing (food); textile; clothing; carpentry and furniture; ceramic, stone and glass; machine (Yamawaki, 2001, p. 132).

At present, the main specializations of clusters in Japan are according to the Japan External Trade Organization data's: automobile and transport equipment; electronic components, devices, semiconductors, precision machinery, biotechnology, healthcare and welfare; ICT and cloud computing; environment and energy; food and other industries. These specializations reflect the current stage of development of the Japanese economy based mainly on innovations.

Specializations of regions based on the clusters are also a current direction of supporting clusters in the European Union. Specializations of European clusters are much more varied. For comparison, according to the report „Star Cluster”, which presents the strongest regional clusters in the United Kingdom according to the European Cluster Observatory star rating. In total, there

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

are 182 clusters in the United Kingdom, that have received at least on star. Specializations of clusters whose companies employ the most workers are:

- business services (1 5340 002 employees);
- financial services (760 676 employees);
- education (597 577 employees).

A comparison of Japanese specialization of clusters based primarily on technological processes and clusters in UK, specializing mainly in services indicates differences between the two regions. Currently, the technology and intellectual property rights in Japan is about 5 times higher than their imports. This makes Japan a country with modern technology know-how and global network of linkages controlled by Japanese capital groups and trade. Taking this into consideration the European Union has a considerable distance to catch up.

Conclusions

Despite the old tradition of forming clusters and a lot of experience of Japan in this respect – the cluster policy is still one of the prior directions of encouraging the economic development of Japan. In 2001-2005, METI (Ministry of Economy, Trade and Industry) began implementation of the Industrial Cluster Plan with a budget of 5 million per year and preferential access to the funds of 350 million euros thanks to which 40 000 new companies were created (Tsuji et al., 2005). Between 2006-2011 the creation of further 40 000 new businesses were planned and works to promote foreign activities as well as self-sufficiency and independence of the created clusters (Bochańczyk-Kupka, 2014).

Currently in Japan a program has started based on three pillars, so-called an economic recovery program. ABE program, also known as a three arrows program, whose objective is a long-term growth strategy (Report, 2013). This program is different from the currently implemented in the European Union policy assuming the reduction of expenditure and reducing budgets. Announced in 2014 the last element of the developed program envisages further support of businesses operating within the clusters. Japan, as other countries is planning the creation of special economic zones, the increasing role of public-private partnerships, e.g. in infrastructure investment.

Measures leading to economic growth as a result of the growth of innovation and competitiveness of the regions (thanks to regional specialization), have also been undertaken in Europe. In accordance with the Europe Strategy 2020 document, one of the main priorities of the European Union economic

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

development based on knowledge and innovation and the related concept of smart specialization conducted also on the base of clusters (Europa 2020).

For the past few years many new clusters have been formed in Europe. In a view of the fact that a lot of them are young organizations with a little resources both financial and human infrastructure, it is expected that much of it in the coming years will remain in the initiation phase of development. The aim of the policy conducted in the European Union is to identify clusters of strategic importance. In Poland, for example they are called National Key Clusters (clusters of strategic importance for the country) and the Regional Key Clusters (analogous: the strategic importance of the region/ regions).

Cluster support requires the identification of the determinants of the effectiveness of their operations. An analysis of the interactions that occur between these factors is also necessary (Hassink, 2005).

A good solution is to use for this purpose methods of multidimensional comparative analysis. It is also important to study the relations between cluster environment and factors directly affecting the functioning of the cluster structures.

Abstract: The purpose of this research is to characterize and evaluate the results of economic development. In order to analyze the changes of economic development in different countries the index of economic development as share of sustainable development is used. The research characterizes economic development of two neighborhood countries – Lithuania and Poland. Empirical analysis of satisfactory cases of Lithuania and Poland during the period of the years 2005-2012 are examined. The point of this research – to analyze a country's main macroeconomic development indicators and unify them creating an economical development index. The year 2005 was taken as the base year.

Introduction

Lithuania and Poland, as neighboring countries, present satisfactory cases of their economic development. The historical, economical, political and cultural development of Lithuania and Poland shares some similarities, but also is different. When comparing the economical development of these countries and determining the advantages of each country, it would be appropriate to analyze their economical policies. In 2004 Lithuania and Poland joined the European Union (together with other 9 Central and Eastern

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

Europe countries). Membership in the EU is an important factor for the cohesion of these countries' economies. Motivation for writing the paper is the situation, that many indicators are used when describing economic development of the individual country. A number of economic researches (Krugman, Wells, 2006, pp. 1-488), (Blanchard, Hoarau, 2011) describe economic development measurement possibilities. Scientific researches show that some indicators which are used seeking to determine the status of the country's development exist. For this reason the most significant economic indicators, such as gross domestic product (GDP), GDP per capita (GDPpc), gross national income (GNI), gross national income per capita (GNIpc), genuine progress indicator (GPI), human development index (HDI), foreign direct investment (FDI), expenditure for research and development (R&D), saving, investment, asset prices, employment, unemployment, inflation interest rate and others indicators or their groups are examined. The position that GDP or GDPpc are incomplete to measure economic performance is broadly characterized by eminent economic scientists Stiglitz, Sen and Fitoussi (Commission on the Measurement of Economic Performance and Social Progress, 2009, pp. 1-292). They conclude, that the committee does not recommend creating a new super-index, which could integrate more economic, social, political, cultural and environmental indicators. The scientists notice that it is best of all to correct shortcomings of GDP, evaluating for example leisure, income inequality.

HDI is created by Sen and Ul-Haq in 1990 and fitted in United Nations Development Programme (Ul-Haq, 1995, pp. 1-288). This determine annually evaluates HDI for each country as members' of the United Nations Organization. The HDI expresses the basic elements of human development (healthy and long life index, adult literacy rate index and standard of living as GDPpc at purchasing power parity (PPP) terms in US dollars), but it does not give full results of economic development (Selim, 2015, p.1-2). The discussions about the possibility to use HDI for the human development comparison between countries enlarges and this indicator was renewed from the year 2010, clarifying firstly, education index and secondly, the standard of living calculating as GNIpc at purchasing power parity (PPP) terms in US dollars. The analysis of scientific literature (Radovanovic, 2011, pp. 193-208) shows, that human development is broader than HDI, due to this reason the level of the country development is described best by the combination of different indicators. Moreover, HDI is criticized for the lack of technological development changes values in it (Wolff et al., 2011, pp.843-870).

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

Another indicator – Self –Organizing Maps (SOM) is based on the HDI components. Rende & Donduran (2011, p. 989-1003) SOMs characterizes as exclusive type of the countries grouped into the clusters, according to their similarities in their development. SOMs creates favorable conditions to analyze the results of neighbor countries clusters development, its causes and the applied economical policies. In this case human development is based on the precondition of the possibility to chose economic policy from the adopted potential neighborhoods in the same cluster. Such behavior of the government institutions of separate countries can help to improve and to increase the structural elements of the index and the total amount of them, calculating SOM.

In the scientific literature the effects of international trade on quality of life and economical development are discussed. Besides the evaluation that the quality of life is deteriorating due to international trade, some authors (Davies, Quinlivan, 2006, pp. 868-876) positively evaluate the increase of international trade, international competitiveness, economic development, which lead to the increase of employment level and social welfare.

The point of this article is to show the results of economical development in Lithuania and Poland in the period of 2005-2012. The analyzed period includes the period before the 2007-2008 global financial crisis, the period of the crisis. The economical development results are analyzed in the article by comparing main macroeconomic indexes. Judging on these indexes, Lithuania and Poland are given an economic development index. The analysis of paper is based on World Bank data statistics, the Statistical Office of Lithuania and the Central Statistical Office of Poland. The point of this article – to analyze a country's main macroeconomic development indexes, characterizes economic development indexes and unifies them creating an economical development index. The goals of the article: to analyze and compare Lithuania's and Poland's main macroeconomic development indexes; to describe indexes that are used to evaluate a country's economical development and create an economical development index and characterize its change in the period of 2005-2012 in the context of the European Union Member States (EU). The research shows the changes of economic development indicators in Lithuania and Poland, seeking cohesiveness with the EU economic development the level in average and in the perspective – to align to the counties' higher economic development level.

Methodology of the research

A number of economic researches describe different economic development measurement possibilities. Due to this reason it is important to determine and to evaluate the changes of economic development using the index of economic development of Lithuania and to compare it with the economic development index of the neighboring country and international cooperation partner from the West – Poland and the EU-28. It is significant to characterize the similarities and the main diversities of the economic development factors in the years 2005-2013 in Lithuania and Poland.

One of the most commonly used methods for the analysis of economic development is the evaluation of main macroeconomic indicators and their changes. In order to describe the changes of economic development the economic development index as part of sustainable development in these countries was count up, also absolute and relative values are given in parallel. The method of the base indexes comparison is applied, whereas the first year of the analyses period is chosen as base year.

The priorities of economic development in Lithuania and Poland are based on the European Commission Strategy “A Strategy for Smart, Sustainable and Inclusive Growth” is significant important. The priorities of the Strategy are: smart development, related to the development based on knowledge and innovation development; sustainable development – substantiated on economical use of resources and competitiveness; and inclusive growth well-grounded on high level of employment, high level of social cohesion among regions and countries. The coordination of the main economic development indicators leads to higher results of economic development. The scientific literature gives some alternatives for the evaluation of economics aspects of sustainable development.

This article seeks to compare economic development among Lithuania and Poland in the context of the EU-28 data such as: GNIpc, foreign direct investment per capita (FDIpc) and employment (E), using World Bank data is analyzed. Based on the given analysis of main macroeconomic indicators, it is determined what is achieved in economic development in analyzed countries. Year 2005 was chosen as a base year for the evaluation of the economic development index in Lithuania, Poland and the EU-28 in the period of 2005-2012 (the index of economic development in year 2005 is equal to 100.0%). This index of economic development characterizes economic development of country, evaluating the changes of three described macroeconomic indicators: 1) GNIpc based on PPP, 2) FDIpc and 3) E.

18-19 June 2015, Economics and Finance**

Due to lack of information it is problematic to define the share of each economic indicator included in this index so the method of equal base weights is used. While evaluating the economic development, only such indicators are taken into calculation, which increase would have a positive effect on economic development (GNIpc, FDIpc and E).

The economic development index (I_{EDV}) is evaluated according to the (1) formula:

$$I_{EDV} = \sum_{i=1}^n ai \times Ii, \quad (1)$$

where ai – is the weight of separate element of economic development indicator;

Ii – is the separate element, indicator involved into index of economic development.

The sum of all three weight separate elements (formula 2) of the economic development indicators is:

$$\sum_{i=1}^n ai = a_1 + a_2 + a_3 = 1. \quad (2)$$

Three indicators are used: indicator of GNIpc (I_{GNIpc}), indicator of FDIpc (I_{FDIpc}) and indicator of employment (I_E). Three indicators take the weighting expression, described in the (3) formula:

$$I_{EDV} = a_1 \times I_{GNIpc} + a_2 \times I_{FDIpc} + a_3 \times I_E, \quad (3)$$

The increase of these indicators means positive effects of economic development; and the decrease of these indicators means negative changes in the economy, related with recession of the economy described.

The economic development indicators

The growth of real GDPpc or economic growth is the most important indicator of economic development, showing living standards in the country. The analysis of real GDP growth is given in Table 1, shows that real GDP was contracted mostly in the year 2009, accordingly in Lithuania

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

it diminished by 14.7%, in the EU – by 4.3% and in the EU euro area – by 4.4%. Real GDP in Poland, unlike in Lithuania, increased during the years 2005-2012. The key factors of economic development in Lithuania and Poland are based, firstly, on the qualified labour force, which is open to new changes and is learning fast. Secondly, economic development is grounded on the efficiency driven factors (as higher education and training; market efficiency; technological readiness) during the years 2005-2007, and from year 2008 to year 2012 – on the economic development factors based on the transition from the efficiency driven to innovation driven factors. As innovation driven factors are evaluated business sophistication and innovation (Shwab, Porter, 2006, pp. 1-598; Schwab, 2012-2013, pp. 1-569).

The structure of agriculture, which creates added value, in the country is one of the most important factors for economical development. After Lithuania and Poland became members of the EU, the possibility of emigration arose. Due to emigration and low birth rates the number of Lithuanian population decreased during the years 2005-2012 by 9.9% and fell from 3.32 million to 2.99 million. The number of population of Poland, in opposite to Lithuania, has increased by 1.0% and has grown from 38.18 million to 38.54 million (or by 380 thousand population). The changes of the number of population in the EU are positive: the number of population has increased by 1.9% (or by 9.24 million population) in comparison with the base year 2005.

The agriculture value added as per cent of GDP in the years 2005-2012 has decreased in Lithuania and Poland, accordingly by 16.7% and 3.0%. The agriculture value added as per cent of GDP in the EU and the EU euro area was stable enough but it both in the EU and both in the EU euro area it was approximately from 3 to 2.4 times less than it was in Lithuania and about 2 times less than it was in Poland.

Industry is very important in the structure of economic activity. Its growth very much depends on open economy and the amount of direct investments into the country from abroad. The industry value added as per cent of GDP has decreased in the years 2005-2012 in Lithuania – by 5.5%; in the EU – by 5.8%; in the EU euro area – by 6.8%. The industry value added in Poland has increased by 2.5% during all analyzed year.

Note: LT –Lithuania; PL –Poland; EUea – EU euro area.

Source: author's calculations based on The World Bank Group Data; Statistical Office of Lithuania, 2015; Central Statistical Office of Poland, 2015.

The value added in service sector in the structure of GDP of all analysed countries had the biggest share among other sectors in the countries. The value added in services in Lithuania, calculated as per cent of GDP, has increased mostly, by 4.3%; in the EU – by 2.8%; in the EU euro area – by 2.8%. The service sector value added in Poland, unlike in Lithuania, has slightly decreased year by year, the reduction in compare with the base year 2005 was 1.1%.

Another important indicator – the level of domestic and foreign income, shown as GNIpc indicator is given in PPP (Table 2) terms in US dollars.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

The GNIpc in Lithuania and in Poland the year 2005 was less than GNIpc of the EU; and the GNIpc in Lithuania was 53.8 % and in Poland 51.1% from the level of the EU GNIpc. The GNIpc level in Lithuania in the year 2005 was 105.2% from the level of the GNIpc in Poland. The GNIpc in Lithuania has increased faster in comparison with Poland until the year 2008, then the growth was equal until the year 2011. The GNIpc in Lithuania in the year 2012 was 66.5% and in Poland 63.0% from the level of the GNIpc in the EU. It should be noted, that the GNIpc in the EU euro area in the year 2005 was by 8.8% bigger than in the EU and such trend continued until the year 2012.

A significant factor of economic development is the supply side factor, such as FDI. The development of different economic sectors depends from the flows of FDI. The FDIpc in Lithuania in the years 2005-2008 was bigger than in Poland. Economic downfall, which Poland did not experience, was in the year 2009. Poland became more attractive for investments from abroad, this is why FDIpc in the years 2009-2011 significantly increased in Poland in comparison with Lithuania. It is noted that FDIpc before the global financial crisis (in the year 2008) was bigger in the EU than in the EU euro area. The FDIpc in EU euro in the year 2009-2011 was bigger than in the EU. It is necessary to note that the FDIpc in Lithuania and Poland and in the EU and EU euro area in the years 2005-2012 had diminishing tendency.

The next factor of economic development is the level of employment. The number of employed persons in Poland increased by 16%, in the EU – by 2.7 % and in the EU euro area – by 1.7%. The number of employed persons in Lithuania in years 2005-2008 increased by 2.5%, but since the year 2009 it began to decline and in 2012 it did not reach the employment level of year 2009.

Economic development index and its structure

The economic development index, according to the described method is calculated and given in Table 3. The calculation shows that different countries achieved different situations. Economic growth in Lithuania slowed down a bit in year 2008 and the downfall manifested in year 2009. Calculated economic development index in 2010 shows, that Lithuanian economy has recovered, but slightly, after the economic downfall. The economic development index in the year 2012 exceed by 2.2% its level in the base year 2005.

The economic development index of Poland in year 2005-2012 was bigger than in the base year value of economic development index. In 2012 economic development index in Poland decreased to its lowest value – 111.7% during the whole period of 2005-2012.

The EU and the EU euro area in year 2012 did not achieve the economic development level of year 2008, because this index was, accordingly, 88.0% and 88.4%. This process was caused by the contraction of FDIpc in these countries. Lithuania and Poland have increased the level of the index in year 2012 and this index was, accordingly, 102.1% and 111.7%.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

The analysis of the changes of economic development index in Lithuania and Poland as neighborhoods countries significantly differs. This difference is due to higher employment level in Poland.

Conclusions

It is significant that the analyzes of structural changes of economic development index allows to characterize main problems of economics policy and shows the most important problems, which are necessary to consider in decision making process and in creating of economic policy. The research listed the neighborhoods countries – Lithuania and Poland – according to used method and determined the level of economic development. According to the used method, Poland is first and Lithuania is second. The analyze shows that the biggest problem of Lithuania economic development is decreased level of employment and diminished level of FDIpc. Due to the

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

same reasons – decline of FDIpc during the analyzed period in comparison with the base year 2005 – the EU and EU euro area economic development index was less than 100%.

Export Versus FDI in Cournot Duopoly Framework

JEL Classification: *F23*

Keywords: *exporting; foreign direct investment; proximity-concentration tradeoff*

Abstract: In this paper we study the choice between exporting and foreign direct investment (FDI) in the Cournot duopoly framework. First, we identify the conditions necessary for exporting and FDI, depending on costs of exporting and the cost of foreign investment. Then, we discuss various proximity-concentration tradeoffs. Finally, we demonstrate that six possible types of equilibriums may emerge depending on various combinations of the key parameters of the model. These equilibriums include: a monopoly FDI equilibrium, a monopoly exporting equilibrium, a domestic monopoly equilibrium, a duopoly FDI equilibrium, a duopoly exporting equilibrium, and no entry equilibrium.

Introduction

There is an extensive literature on the relationship between exporting and FDI. In this literature several strands can be distinguished. According to the earliest strand, based on the neoclassical theory of international capital flows, FDI and trade were seen as substitutes (Mundell, 1957). This approach was, however, criticized because of relying on the set of unrealistic assumptions, such as constant returns to scale (CRS) and perfect compe-

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

tion, which were not in line with the key stylized facts on FDI.¹ Another problem was that in the neoclassical approach firms were infinitely small and it was not possible to study directly the investment decisions that took place within the firm.

Therefore, in the 1970s the next strand that attempted to model the firm decision to produce abroad under increasing returns and imperfect competition was initiated. In particular, Copithorne (1971), Horst (1971), and Hirsch (1976) attempted to model an exporting versus FDI decision of a monopolist using a partial equilibrium framework.² In this framework the firm faced a trade-off between proximity to the foreign market obtained by setting up production plants abroad, which allowed to economize on transportation and tariff costs, and concentration of production in the home country and serving foreign markets by exporting, which allowed to save on fixed costs of duplicating production capacity abroad. According to this framework firms invest abroad in those industries in which the gains from avoiding trade costs outweigh the costs of setting up production plants abroad.

In the 1980s the New Theory of Multinational Enterprise (NTME) has been developed. The development of the NTME has been the consequence of the emergence of the New Trade Theory (NTT) in the late 1970s and early 1980s that was based on the tools borrowed from the industrial organization (IO) literature. The NTT models embedded increasing returns to scale and imperfectly competitive market structures such as perfect monopolistic competition or oligopoly. Although particular models differed with respect to assumptions concerning the market structure, their main prediction was very similar: firms are more likely to enter the foreign market via FDI rather than via exporting the higher the trade costs and the lower fixed costs of entry and the size of economies of scale at the plant level compared to the firm level.

Krugman (1983) made one of the earliest attempts to formally integrate MNEs into the NTT. He extended his earlier general equilibrium model of international trade under monopolistic competition (Krugman, 1979, 1980)

¹ See, for example, Markusen (2002), Barba Navaretti and Venables (2004) and Caves (2007). In particular, Markusen (2002, p. 6) noted that: i) "large differences exist across industries in the degree to which production and sales are accounted for by multinational firms", ii) "multinationals tend to be important in industries that a) have high levels of R&D relative to sales, b) employ large number of professional and technical workers as a percentage of their total workforces, c) produce new and/or technologically complex products".

² See chapter 2 in Caves (2007) for a survey of the early literature on the choice between exporting and FDI.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

to introduce the possibility of multinational production. He considered a simple two country framework with labor as the sole factor of production. In addition he assumed that countries were exactly the same in terms of their labor endowments. The symmetry of the model setup implied wage equalization across countries which greatly simplified the analysis.³ However, despite its great analytical convenience, the framework assuming monopolistic competition is not very helpful with regard to studying the strategic interactions between competing firms as in this framework firms simply neglect the actions of their rivals.

Therefore, the alternative approach based on the partial equilibrium model of oligopolistic competition was developed by Markusen (1984). His model assumes the existence of firm-level scale economies as the driving force for FDI. The MNE's headquarter produces a service of a firm-specific asset that can be simultaneously used in multiple plants in a non-rival manner. As a result, two-plant firms have lower fixed costs than those of two single plants and this motivates multinational production.

The original approach proposed by Markusen (1984) was extended in the number of follow-up studies, including Horstmann and Markusen (1987, 1992), Markusen and Venables (1998, 2000) and Markusen (2002, ch. 4) who allowed for endogenous market structures and different forms of imperfect competition. In their models firms had different potential channels of entering a foreign market and each of these channels incurred different costs. A firm faced a choice between concentrating production in the home country and serving foreign markets exporting to achieve scale economies and producing abroad to benefit from proximity to consumers. Their models, however, usually assumed that firm entry decisions were made simultaneously in the first stage of the game.⁴

³ More complex two factor models based on monopolistic competition were proposed by Markusen and Venables (1998) and Markusen (2002, ch.8). However, their models could not be solved analytically and the authors had to rely on numerical methods to study the properties of the equilibrium solutions. Helpman *et al.* (2004) generalized Krugman (1983) model, retaining the assumption of labor as a single factor of production, to study the role of labor productivity in the choice between exporting and FDI. They demonstrated that only firms with highly productive workers can enter foreign markets via FDI, with less productive workers enter via exporting and firms with the least productive workers do not enter foreign markets at all. More recently, Krugman (1983) model has been also extended by Cieřlik (2013) to allow for differences between countries in terms of their size.

⁴ The well-known exception is a two-period duopoly model presented in Chapter 4 of Markusen (2002). This model builds on the earlier framework by Horstmann and Markusen (1987) in which the MNE moves first while the potential entrant can choose to enter at the same time or wait until the next period.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

The representative example of this extended approach is the formal model developed by Horstmann and Markusen (1992) in which firms from home and foreign countries simultaneously decided between: not entering; entering with one plant supplying both markets; and entering with two plants, each supplying local customers. In their model three equilibriums were possible: a classical duopoly with two single-plant firms; a monopoly with one plant in each country; and a duopoly where both firms had plants in two countries. The first equilibrium emerged when plant specific costs were large relative to firm specific and trade costs. The second equilibrium emerged when trade and firm-specific costs were so high that two firms could not be profitable. Finally, the third equilibrium emerged with low plant specific costs.

In contrast to the aforementioned approach, Smith (1987) and Motta (1992) provided an alternative framework to study the choice between exporting and FDI in which entry decisions were made sequentially and the game between two competing firms unfolded as follows. In first stage the foreign firm decided whether or not to establish a subsidiary in the foreign country. In the second stage, the indigenous firm from the host country decided whether to enter the market or not, and then firms engaged in Cournot quantity competition. Their models assumed that entry decisions were made taking into account their effects on the subsequent quantity equilibrium.

Despite the fact that the theoretical studies by Smith (1987) and Motta (1992) provided descriptions of particular equilibriums that may emerge in their framework they did not devote much attention to the proximity-concentration tradeoffs the constitute the central plank of the NTME. Therefore, the main goal of the paper is to study the role of the proximity-concentration tradeoffs in the choice between exporting and FDI in the context of the Smith-Motta framework. The contribution of this paper to the literature is purely theoretical. In particular, we provide both formal quantitative and graphical characterization of each proximity concentration tradeoff and the resulting equilibriums. In addition, we also summarize all possible equilibriums that may emerge depending on various participation constraints in a single table. This allows us to identify the necessary conditions for each equilibrium that may emerge as the outcomes of the Smith-Motta model and derive a broader set of conclusions. Therefore, this paper can be seen as an extension of the aforementioned studies.

The organization of this paper is as follows. Section 2 describes the key assumptions of the model. Section 3 discusses payoffs and participation

constraints associated with particular market entry strategies. Section 4 discusses various proximity-concentration tradeoffs facing the foreign firm. Section 5 characterizes six possible types of equilibriums that may emerge. Finally, Section 6 summarizes and provides directions for further research.

Methodology of the research

In this section we describe the methodology of the research and the main assumptions of the model. To study the choice between exporting and FDI we use a simple single-country Cournot oligopoly framework. In particular, we assume that there are only two firms in the domestic country that operate in a single industry: the domestic and foreign firms that are not capacity constrained. For simplicity, it is rather assumed that the good produced by both firms is homogenous and produced under increasing returns to scale. Increasing returns to scale are modeled by assuming that the total cost function is:

$$TC(x) = F + G + cx \tag{1}$$

where: F is the fixed sunk cost of developing the product, G is the fixed sunk investment cost of entering the market (i.e. building a production plant), c is the constant marginal cost of production and x is output. It can be noted that the average cost of production declines with output as the fixed sunk costs are spread over a larger number of units: $AC(x) = (F+G)/x + c$.

It is assumed that the marginal cost of production c is exactly the same for both foreign and domestic firms. In addition, we assume that if the domestic firm decides to enter the market it must incur both the fixed sunk cost of developing the product F and the fixed sunk cost of building the plant G . However, we assume that the fixed sunk cost F does not apply to the foreign firm as it was incurred in the past when the foreign firm entered the market in its home country. Further, the fixed sunk cost G applies to the foreign firm only when it enters the domestic country market via FDI. If the foreign firm decides to export instead of doing FDI it can save the fixed sunk cost but it has to pay a higher marginal cost. Following Smith (1987), we assume that in addition to the per unit cost of production c the foreign firm has to pay the trade costs which consist of two components: transport

cost s and tariff t which increase the marginal cost. The transport cost and the tariff are assumed to be exogenously given.

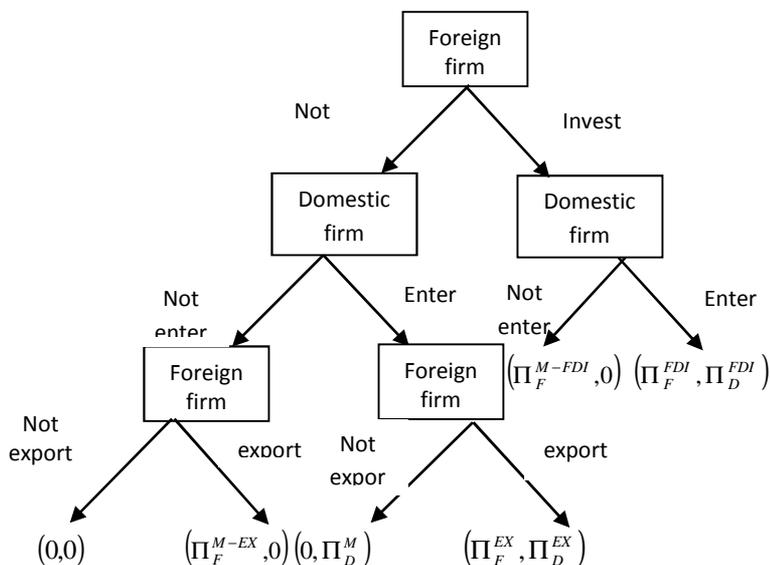

For simplicity, we use an explicit simple linear inverse demand function that relates price P to total output X supplied by both firms to the market:

$$P(X) = a - X, \tag{2}$$

where $a > c$ is the market size in the domestic country. X is the sum of output supplied to the market by both firms: $X = x_F + x_D$, where x_F (x_D) denotes output supplied by the foreign (domestic) firm.

Following Motta (1992) the extensive form of the game between the foreign and domestic firms is illustrated in Figure 1.

Figure 1. The extensive form of the game between the foreign and domestic firms

Source: own elaboration based on Motta (1992).

Figure 1 shows the sequence of all the possible actions and outcomes for domestic and foreign firms.⁵ Each line represents an action, and each box

⁵ It must be noted that the structure of the game proposed by Motta (1992) is different from Smith (1987). In particular, the time structure underlines different degrees of irreversi-

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

represents a decision point. The outcomes of actions are shown in parentheses, where the foreign firm's profits are listed first.

In the first stage of the game the foreign firm decides whether to do FDI and incur the fixed sunk cost G of building the plant in the host country or not. Looking at this choice in the second stage of the game the domestic firm decides whether to enter the market and pay the fixed sunk cost $F+G$ or not. If both firms incurred the sunk costs, they play a standard Cournot output game. In this case the foreign firm earns FDI duopoly profit Π_F^{FDI} , while the domestic firm Π_D^{FDI} . If the foreign firm built the production capacity in the host country market while the domestic firm did not enter the market, the foreign firm captures the entire market and makes FDI monopoly profit Π_F^{M-FDI} .

If the foreign firm decided not to do FDI in the first stage of the game and the domestic firm entered the host country market in the second stage of the game, the foreign firm chooses whether to serve it via exporting and pay trade costs $s+t$ per unit of exports or not to sell in that market at all. If the foreign firm decides to export, a third stage of the game comes into play in which the two firms play the standard Cournot game. In this case the foreign firm earns exporting duopoly profit Π_F^{EX} and the domestic firm Π_D^{EX} . However, if the foreign firm decides not to export the domestic firm becomes the monopolist and earns profit Π_D^M .

Finally, if the foreign firm decided not to do FDI in the first stage of the game and the domestic firm decided not to enter the market in the second stage of the game, the foreign firm chooses again whether to export or not to sell in the host country market at all. If it exports, it becomes an exporting monopolist in that market and earns profit Π_F^{M-EX} . If it does not enter then the demand in the host country is left unserved.

bility involved in firms' decisions. A decision to export by the foreign firm or decision not to enter by the home firm is a decision that can be reversed once the rival firm has made its decision whereas the entry and foreign direct investment are the long-run decisions. Also the set of strategies available to the foreign firm is extended to allow for the option of not entering at all the market in the domestic country which was a priori excluded in Smith (1987). Therefore, the approach proposed by Motta (1992) can be treated as a generalization of Smith (1992).

Payoffs and participation constraints

In this section we discuss the payoffs associated with particular entry strategies, and participation constraints that imply non-negative levels of profits for foreign and domestic firms. First, we consider the case when the fixed sunk market entry costs for the domestic firm ($F + G$) are so high that the domestic firm decides not to enter the market in the domestic country and the foreign firm becomes a monopolist in the domestic market and discuss two standard host market entry strategies: FDI and exporting of the foreign firm. Then, we discuss a more complex case when then foreign firm has to compete with the domestic firm in the Cournot manner.

FDI monopoly

If the foreign firm decides to serve the domestic market via FDI it must incur the fixed sunk cost of building the plant G in the domestic country and its profit function can be written as:

$$\Pi_F^{M-FDI} = [a - X_F^{M-FDI}]X_F^{M-FDI} - cX_F^{M-FDI} - G \quad (3)$$

Using the first order condition we can obtain the FDI monopoly equilibrium output:

$$X_F^{M-FDI} = \frac{a - c}{2} \quad (4)$$

The equilibrium monopoly price in the domestic market can be determined by substituting the FDI monopoly equilibrium output of the foreign firm (4) into the inverse demand function (2) which yields:

$$p_F^{M-FDI} = \frac{a + c}{2} \quad (5)$$

Substituting equilibrium solutions for output (4) and price (5) into the profit function (3) yields the equilibrium monopoly profit from FDI for the foreign firm:

$$\Pi_F^{M-FDI} = \left(\frac{a - c}{2}\right)^2 - G = [X_F^{M-FDI}]^2 - G \quad (6)$$

The foreign firm enters the domestic country market via FDI only if its operating profit is bigger than the fixed cost of entry:

$$G < \left(\frac{a-c}{2} \right)^2 \quad (7)$$

Exporting monopoly

If the foreign firm decides to serve the domestic market by exporting its profit function can be written as:

$$\Pi_F^{M-EX} = [a - X_F^{M-EX}] X_F^{M-EX} - (c + s + t) X_F^{M-EX} \quad (8)$$

Using the first order condition, we can obtain the exporting monopoly equilibrium output:

$$X_F^{M-EX} = \frac{a - c - s - t}{2} \quad (9)$$

The equilibrium monopoly price in the domestic market can be determined by substituting the exporting monopoly equilibrium output of the foreign firm (9) into the inverse demand function (2) which yields:

$$p_F^{M-EX} = \frac{a + c + s + t}{2} \quad (10)$$

Substituting equilibrium solutions for output (9) and price (10) into the profit function (8) yields the equilibrium monopoly profit from exporting:

$$\Pi_F^{M-EX} = \left(\frac{a - c - s - t}{2} \right)^2 = [X_F^{M-EX}]^2 \quad (11)$$

The foreign firm enters the market in the domestic country via exporting only if its profit in that market is positive which implies the following participation constraint:

$$s + t < a - c \quad (12)$$

Domestic monopoly

We also consider the autarky case when the domestic market entry costs are so high that the foreign firm cannot enter the market and the domestic firm enjoys a monopoly power. In this case the profit function of the domestic monopolist can be written as:

$$\Pi_D^M = [a - X_D^M]X_D^M - cX_D^M - F - G \quad (13)$$

Using the first order condition we can determine the domestic monopoly equilibrium output:

$$X_D^M = \frac{a - c}{2} \quad (14)$$

The equilibrium monopoly price in the domestic market can be determined by substituting the equilibrium monopoly output (14) into the inverse demand function (2) which yields:

$$p_D^M = \frac{a + c}{2} \quad (15)$$

Substituting equilibrium solutions for output (14) and price (15) into the profit function (13) we obtain the equilibrium monopoly profit for the domestic firm:

$$\Pi_D^M = \left(\frac{a - c}{2} \right)^2 - F - G = [x_D^M]^2 - F - G \quad (16)$$

The domestic monopolist is active in the domestic market if the following market participation constraint is satisfied:

$$F + G < \left(\frac{a - c}{2} \right)^2 \quad (17)$$

FDI Cournot duopoly

If foreign firm decides to enter the domestic market via FDI and the domestic firm decides to compete we have the FDI Cournot duopoly problem. In this case if the foreign firm enters the market in the host country and competes with the domestic firm its profit function can be written as:

$$\Pi_F^{FDI} = [a - (x_F^{FDI} + x_D^{FDI})]x_F^{FDI} - cx_F^{FDI} - G \quad (18)$$

In a similar way we can write down the profit function of the domestic firm:

$$\Pi_D^{FDI} = [a - (x_F^{FDI} + x_D^{FDI})]x_D^{FDI} - cx_D^{FDI} - F - G \quad (19)$$

Using the first order conditions for the domestic and foreign firms the outputs supplied by both firms to the domestic market can be written as, respectively:

$$x_F^{FDI} = \frac{a - c}{3} \quad (20)$$

$$x_D^{FDI} = \frac{a - c}{3} \quad (21)$$

We can note that the volumes of output supplied by the foreign and domestic firms to the host country market when the foreign firm enters via FDI and faces competition from the domestic firm are exactly the same.

The total equilibrium level of output supplied to the host-country market is the sum of outputs (20)-(21) supplied jointly by the foreign and domestic firms which can be written as:

$$X^{FDI} = x_D^{FDI} + x_F^{FDI} = \frac{2(a - c)}{3} > X_F^M = X_D^M \quad (22)$$

It can be easily noted that the total level of output supplied to the market is now bigger compared to the previously discussed monopoly FDI and

domestic firm equilibriums due to competition between firm. As the equilibrium level of output is now bigger the equilibrium price is lower. The equilibrium price in the domestic market can be determined by substituting the sum of output (22) into the inverse demand function (2) to obtain:

$$p^{FDI} = \frac{a+2c}{3} < p_D^M = p_F^{M-FDI} = \frac{a+c}{2} \quad (23)$$

Using our solutions for the equilibrium quantities (20)-(21) and price (23) the total profits for the foreign and domestic firms can be written as, respectively:

$$\Pi_F^{FDI} = \left(\frac{a-c}{3}\right)^2 - G = [x_F^{FDI}]^2 - G \quad (24)$$

$$\Pi_D^{FDI} = \left(\frac{a-c}{3}\right)^2 - F - G = [x_D^{FDI}]^2 - F - G \quad (25)$$

It can be noted that the operating profits of both firms are now lower compared to the FDI and domestic monopoly equilibriums as now firms have to compete with each other. Moreover, the overall profit of the foreign firm is bigger compared to the profit of the domestic firm as it has to pay a fixed market entry cost F in addition to the fixed cost of building the plant G .

To ensure that both firms are active in the host-country market we need to impose the market participation constraints stating that both firms have non-negative levels of equilibrium profits. These conditions require that operating profits in the domestic market must be bigger than the fixed costs. The participation constraint for the foreign firm requires that

$$G < \left(\frac{a-c}{3}\right)^2 \quad (26)$$

The participation constraint for the domestic firm requires that

$$F + G < \left(\frac{a - c}{3} \right)^2 \quad (27)$$

It can be noted that it is easier to satisfy the participation constraint for the foreign firm than for the domestic firm, hence if (27) is satisfied then also (26) is satisfied. If participation constraints are met, then both firms have non-negative profits and supply positive amounts of output to the domestic market.

Exporting Cournot duopoly

If the foreign firm decides to enter the domestic market via exporting and the domestic firm decides to compete we have an exporting Cournot duopoly problem. In this case the profit function of the foreign firm can be written as:

$$\Pi_F^{EX} = [a - (x_F^{EX} + x_D^{EX})]x_F^{EX} - (c + s + t)x_F^{EX} \quad (28)$$

For the foreign firm exporting to the domestic market from the production facility located abroad implies a high marginal cost option due to the existence of transport costs s and tariffs t . However, this strategy allows the foreign firm to save on the fixed cost of investment G .

In this case the profit function for the domestic firm can be written as:

$$\Pi_D^{EX} = [a - (x_F^{EX} + x_D^{EX})]x_D^{EX} - cx_D^{EX} - F - G \quad (29)$$

Using the first order conditions, we can determine the equilibrium levels of output supplied by the foreign and domestic firms to the domestic market, respectively:

$$x_F^{EX} = \frac{a - c - 2(s + t)}{3} \quad (30)$$

$$x_D^{EX} = \frac{a - c + (s + t)}{3} \quad (31)$$

We can note that compared to FDI solutions now the equilibrium levels of output contain the transport cost and the tariff. As a result the domestic

firm's output is higher and the foreign firm's output is lower compared to the earlier case when the foreign firm serves the domestic market via FDI. In the special case when trade is completely free, i.e. $s + t = 0$ the output levels of both firms are the same as in the previous case.

The total equilibrium level of output supplied to the domestic market is the sum of outputs (30)-(31) supplied jointly by the foreign and domestic firms that equals:

$$X^{EX} = x_D^{EX} + x_F^{EX} = \frac{2(a-c) - (s+t)}{3} < X^{FDI} \quad (32)$$

It can be noted that the equilibrium level of total output supplied to the domestic market when the foreign firm enters this market via exporting is smaller compared to compared to the equilibrium level of output in the case when it enters via FDI (18) due to the inefficiencies associated with the existence of the transport cost and the tariff.

The equilibrium price in the domestic market can be determined by substituting the sum of output (32) into the inverse demand function (2) which yields:

$$p^{EX} = \frac{a + 2c + s + t}{3} > p^{FDI} \quad (33)$$

It can be noted that the price in the exporting Cournot equilibrium will always be higher compared to the FDI Cournot equilibrium due to the technical inefficiency associated with the existence of the trade cost.

Using our solutions for the equilibrium quantities (30)-(31) and the equilibrium price (33) we can determine the equilibrium profits for the domestic and foreign firms, respectively:

$$\Pi_F^{EX} = \left(\frac{a - c - 2(s+t)}{3} \right)^2 = [x_F^{EX}]^2 \quad (34)$$

$$\begin{aligned} \Pi_D^{EX} &= \left(\frac{a - c + s + t}{3} \right)^2 - F - G > \Pi_D^{FDI} \\ &= [x_D^{EX}]^2 - F - G \end{aligned} \quad (35)$$

It can be noted that for the domestic firm it is always better if the foreign firm enters the domestic market via exporting rather than via FDI. The domestic firm's profit is higher when the foreign firm exports than when it enters via FDI for two reasons: i) the domestic firm's larger sales, ii) a higher equilibrium price. Hence, for the domestic firm $\Pi_D^{EX} > \Pi_D^{FDI}$ is always satisfied.

However, for the foreign firm such a simple generalization cannot be made. Although the operating profit associated with FDI is higher than the exporting profit, the fixed cost of investment G can make the foreign firm's overall profit of FDI lower than the profit from exporting. Hence, whether the profit from exporting is bigger or smaller compared to the profit from FDI for the foreign firm depends on the interplay between the trade and investment costs ($s + t$ and G). This 'proximity-concentration' tradeoff will be studied in the next section.

To ensure both firms are active in the domestic market we must impose market participation constraints on the domestic and foreign firms stating that they must have non-negative levels of profits. The participation constraint for the foreign firm requires that:

$$2(s + t) < a - c \quad (36)$$

Similarly, the participation constraint for the domestic firm requires that:

$$F + G < \left(\frac{a - c + s + t}{3} \right)^2 \quad (37)$$

It can be noted that now it is easier for the domestic firm to satisfy the participation constraint as it has a higher operating profit compared to the previous case when the foreign firm entered the domestic market via FDI. If both (36) and (37) are satisfied, then both firms have non-negative profits and supply positive amounts of output to the domestic market.

Proximity-concentration tradeoffs

In this section we discuss various proximity-concentration tradeoffs facing the foreign firm. First, we discuss the tradeoff between FDI monopoly and exporting monopoly for the foreign firm, then the tradeoff between FDI

and exporting under duopoly, and finally we discuss the tradeoff between FDI monopoly and exporting duopoly.

Tradeoff between FDI monopoly and exporting monopoly

To study the tradeoff between FDI monopoly and exporting monopoly we compare profits of the foreign firm for FDI monopoly (6) and exporting monopoly (11). The profits of the foreign firm from FDI monopoly and exporting monopoly are equal when:

$$G = \frac{2(a-c)(s+t) - (s+t)^2}{4} \quad (38)$$

If the fixed cost of investment G is bigger (smaller) than the threshold value (38) the foreign firm prefers exporting (FDI) monopoly to FDI (exporting) monopoly.

Tradeoff between FDI duopoly and exporting duopoly

To analyze the tradeoff between FDI duopoly and exporting duopoly we compare profits of the foreign firm from FDI duopoly (24) and exporting duopoly (34). The profits of the foreign firm from exporting duopoly and FDI duopoly are equal when:

$$G = \frac{4(a-c)(s+t) - 4(s+t)^2}{9} \quad (39)$$

If G is bigger (smaller) than the threshold value (39) then exporting (FDI) is the preferred entry strategy for the foreign firm. It can be noted that threshold value of the fixed cost (39) is bigger than (38). This means that increased competition in the domestic market makes the entry of the foreign firm via FDI less likely. Moreover, FDI can always be a preferred to exporting for certain combinations of model parameters such as the high trade cost and the low fixed cost of investment. Similarly, exporting can always be a preferred to FDI for certain combinations of model parameters such as the low trade cost and the high fixed cost of investment.

Tradeoff between FDI monopoly and exporting duopoly

To analyze the tradeoff between FDI monopoly and exporting duopoly we compare profits of foreign firm from FDI monopoly (6) and exporting duopoly (35). The profits of the foreign firm from FDI monopoly and exporting duopoly are equal when:

$$G = \frac{5(a-c)^2}{36} + \frac{4(a-c)(s+t) - 4(s+t)^2}{9} \quad (40)$$

If the fixed cost of investment G is bigger (smaller) than the threshold value (40) then exporting (FDI) is the preferred entry strategy for the foreign firm. In addition, FDI can always be a preferred to exporting for certain combinations of model parameters such as the high trade cost and the low fixed cost of investment. Similarly, exporting can always be a preferred to FDI for certain combinations of model parameters such as the low trade cost and the high fixed cost of investment.

Equilibriums

In this model six possible equilibriums may emerge depending on various combinations of the key parameters of models: a FDI monopoly equilibrium, an exporting monopoly equilibrium, a domestic monopoly equilibrium, a FDI duopoly equilibrium, an exporting duopoly equilibrium, and a no-entry equilibrium.

To identify those equilibriums we distinguish between three types of trade and investment costs for the foreign firm: low (i.e. $2(s+t) < a-c$ and $G < \left(\frac{a-c}{3}\right)^2$, respectively), high (i.e. $a-c < 2(s+t) < 2(a-c)$ and $\left(\frac{a-c}{3}\right)^2 < G < \left(\frac{a-c}{2}\right)^2$, respectively), and prohibitively high (i.e. $(s+t) > a-c$ and $G > \left(\frac{a-c}{2}\right)^2$, respectively). When low costs occur the foreign firm is able to enter the host market and compete with the domestic firm. When high costs occur the foreign firm is able to enter the host market only if the domestic firm does not enter. Finally, when these costs are prohibitively high the foreign firm does not enter at all.

We also distinguish four different ranges of the fixed sunk costs for the domestic firm: low (i.e. $F + G < \left(\frac{a-c}{3}\right)^2$), high (i.e., $\left(\frac{a-c}{3}\right)^2 < F + G < \left(\frac{a-c+s+t}{3}\right)^2$), very high (i.e. $\left(\frac{a-c}{2}\right)^2 > F + G > \left(\frac{a-c+s+t}{3}\right)^2$) and prohibitively high (i.e. $F + G > \left(\frac{a-c}{2}\right)^2$). When the low fixed costs occur

the domestic firm is able to compete with the foreign firm irrespectively of its entry strategy. When the high fixed costs occur then the domestic firm is able to compete with the foreign firm only when it exports. When the fixed costs are very high the domestic firm can enter only when the foreign firm does not enter. Finally, when the costs are prohibitively high the domestic firm does not enter irrespectively of the decision of the foreign firm.

We start with the discussion of the benchmark equilibriums in which the domestic firm decides not to enter the market and the foreign firm becomes a monopolist serving the host country market either via FDI or via exporting. Then, we describe FDI and exporting duopoly equilibriums. Finally, we discuss the domestic monopoly and no entry equilibriums.

The FDI monopoly equilibriums may occur when the domestic firm is unable to compete with the foreign firm irrespectively of its entry strategy (i.e. when the fixed sunk costs are very high), or only when it enters via FDI (i.e. when the fixed sunk costs are high) or when the domestic firm does not enter the market at all (i.e. the fixed sunk costs are prohibitively high).

If the fixed sunk costs are high the domestic firm is unable to compete with the foreign firm only when it enters via FDI and both trade and investment costs are low then there is no tradeoff. This is because the foreign firm always chooses FDI to capture the entire market in the host country instead of having to share the market with the domestic firm when exporting. However, if the trade costs are low while the investment cost is high then the foreign firm faces the tradeoff between becoming a monopolist when it enters via FDI and sharing the market with the local firm when it exports. Hence, it chooses FDI and becomes the monopolist only if the investment cost is below the threshold level (40). Moreover, the foreign firm chooses FDI and becomes the monopolist when: i) the trade costs are high and the investment cost is low, ii) both trade and investment costs are high, iii) the trade costs are prohibitively high and the investment cost is

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

low, and iv) the trade cost are prohibitively high and the investment cost is high.

If the fixed sunk costs are very high the domestic firm is unable to compete with the foreign firm irrespectively of its entry strategy and both trade and investment cost are low then foreign firm faces the tradeoff between FDI and exporting. It chooses FDI only if the investment cost is below the threshold level (38). Similarly, if the trade costs are low and the investment cost is high or when both trade and investment costs are high the foreign firm chooses FDI only if the investment cost is below the threshold level (38). Moreover, the foreign firm chooses FDI and becomes the monopolist when: i) the trade costs are high and the investment cost is low, ii) the trade costs are prohibitively high and the investment cost is low, and iii) the trade cost are prohibitively high and the investment cost is high.

Also, if the fixed sunk costs are prohibitively high the domestic firm is unable to survive in the market even as a monopolist and both trade and investment cost are low then foreign firm faces the tradeoff between FDI and exporting. It chooses FDI only if the investment cost is below the threshold level (38). If the trade costs are low and the investment cost is high or when both trade and investment costs are high the foreign firm chooses FDI only if the investment cost is below the threshold level (38). In addition, the foreign firm chooses FDI and becomes the monopolist when: i) the trade costs are high and the investment cost is low, ii) the trade costs are prohibitively high and the investment cost is low, and iii) the trade cost are prohibitively high and the investment cost is high.

Exporting monopoly equilibriums may occur only when the domestic firm is unable to compete with the foreign firm irrespectively of its entry strategy. This occurs when the fixed sunk costs for the domestic firm are very high or prohibitively high. If both trade and investment cost are low then the foreign firm faces the tradeoff between FDI and exporting. It chooses exporting only if the investment cost is above the threshold level (38). Similarly, if the trade costs are low and the investment cost is high or when both the trade and investment costs are high the foreign firm chooses exporting only if the investment cost is above the threshold level (38). In addition, the foreign firm chooses exporting and becomes the monopolist when: i) the trade costs are low and the investment cost is prohibitively high, and ii) the trade costs are high and the investment cost is prohibitively high.

Next, we discuss the duopoly equilibriums in which the domestic firm decides to enter the market and compete with the foreign firm. The duopoly

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

FDI equilibriums occur only when the the fixed sunk costs are low and domestic firm is able to compete with the foreign firm irrespectively of its entry strategy. If both trade and investment costs are low the foreign firm faces a tradeoff between FDI and exporting. It chooses FDI only if the investment cost is below the threshold level (39). Moreover, the foreign firm always chooses FDI when: i) the trade costs are high and the investment cost is low, and ii) the trade costs are prohibitively high and the investment cost is low.

The duopoly exporting equilibriums occur when the domestic firm is able to compete with the foreign firm irrespectively of its entry strategy, or only when it exports. If the fixed sunk costs are low and the domestic firm is able to compete with the foreign firm irrespectively of its entry strategy and both trade and investment costs are low the foreign firm faces a tradeoff between FDI and exporting. It chooses exporting only if the investment cost is above the threshold level (39). In addition, the foreign firm always chooses exporting when: i) the trade costs are low and the investment cost is high, and ii) the trade costs are low and the investment cost is prohibitively high.

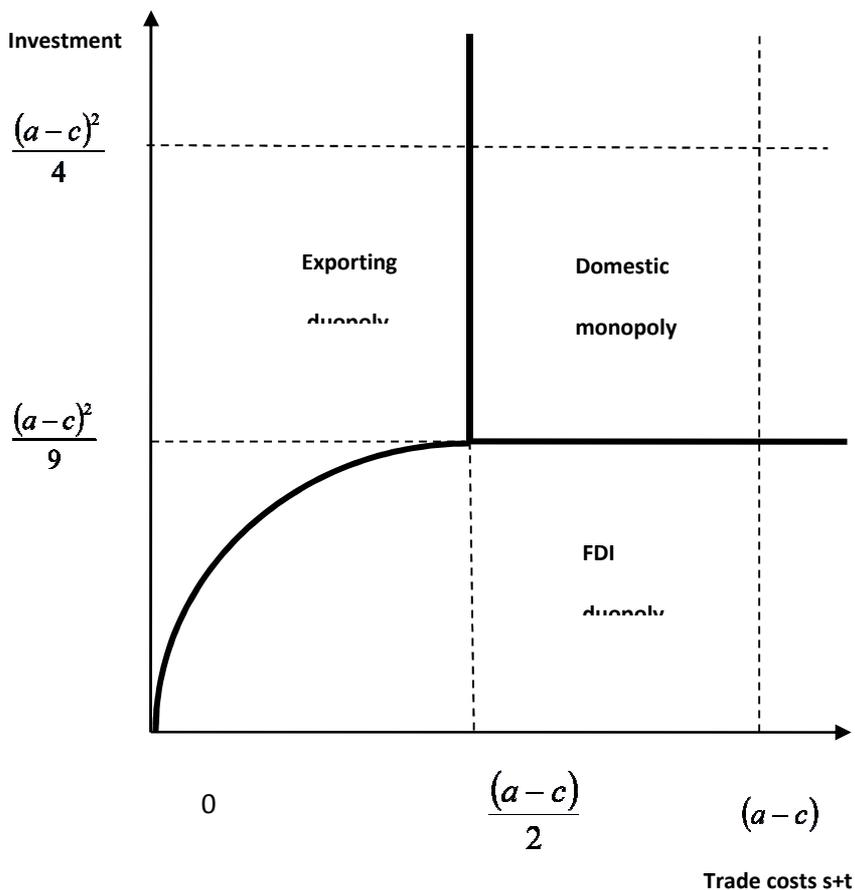

If the fixed sunk costs are high and the domestic firm is able to compete with the foreign firm only when it exports and the trade costs are low while the investment cost is high the foreign firm faces a tradeoff between becoming a monopolist when it enters via FDI and sharing the market with the local firm when it exports. It chooses exporting only if the investment cost is above the threshold level (40). Moreover, the exporting duopoly equilibrium occurs when the trade costs are low and the investment cost is prohibitively high.

Finally, the domestic monopoly equilibrium occurs if the fixed sunk costs are low, and the domestic firm is able to compete with the foreign firm irrespectively of its entry strategy, when: i) both trade and investment costs are high, ii) the trade costs are high and the investment cost is prohibitively high, iii) the trade costs are prohibitively high and the investment cost is high, and iv) both trade and investment costs are prohibitively high. Similarly, the domestic monopoly equilibrium occurs if the fixed sunk costs are high, and the domestic firm is able to compete with the foreign firm irrespectively of its entry strategy, when: i) the trade costs are high and the investment cost is prohibitively high, and ii) both trade and investment costs are prohibitively high. If the fixed sunk costs for the domestic firm are very high the domestic monopoly equilibrium occurs only if both trade and investment costs for the foreign firm are prohibitively high. The no

entry equilibrium occurs only when the fixed sunk costs for the domestic firm are prohibitively high and both trade and investment costs for the foreign firm are prohibitively high.

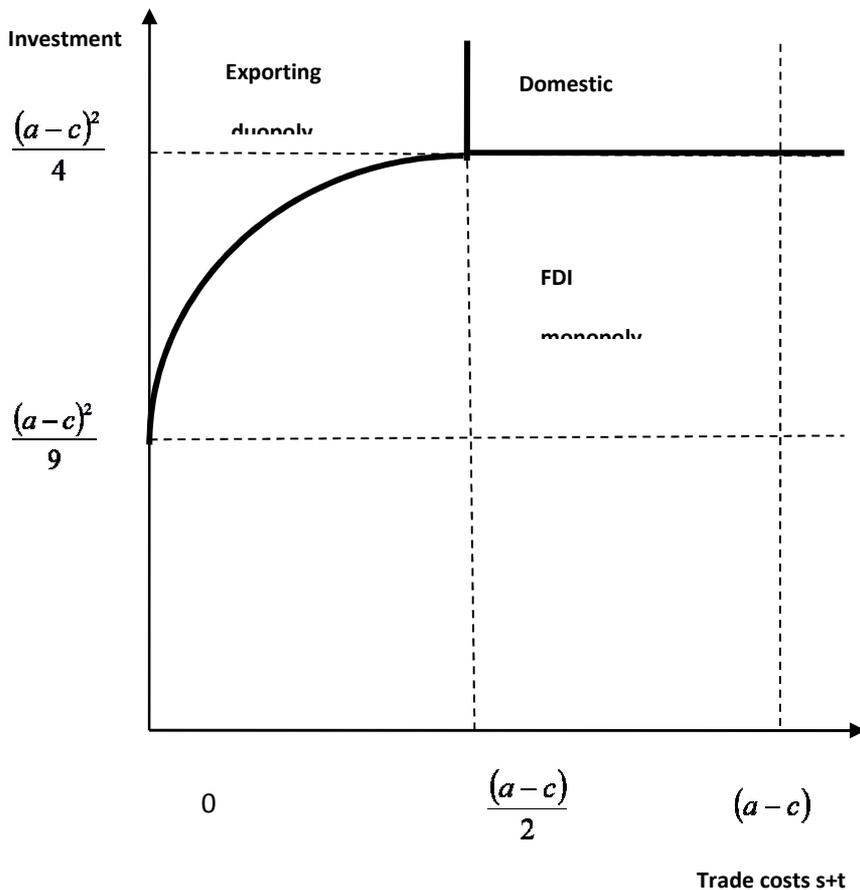

Figures 2-5 and Table 1 provide the summary of the results for different cases of ranges of participation constraints for domestic and foreign firms as well as tradeoffs between FDI and exporting.

Conclusions

In this paper we investigated the role of the proximity-concentration trade-off in the choice between exporting and FDI in the context of the Smith-Motta model. First, we identified the conditions necessary for exporting and FDI, depending on the trade costs and the cost of foreign direct investment. Then, we demonstrated that six types of possible equilibriums might emerge depending on various combinations of the parameters of the model: the monopoly FDI equilibrium, the monopoly exporting equilibrium, the domestic monopoly equilibrium, the FDI duopoly equilibrium, the exporting duopoly equilibrium and no entry equilibrium.

The theoretical framework employed in this paper was, however, based on very specific assumptions. In particular, it was assumed for simplicity that the demand function was linear. Therefore, in future studies it would be useful to investigate whether the theoretical findings reported in this paper generalize to other demand functions, for example such as iso-elastic demand functions derived from CES utility. Moreover, it was assumed that the firms were equally productive and not capacity constrained. Therefore, it would be useful to relax these assumptions in future theoretical studies. Finally, in this paper we did not study the antitrust policy and welfare implications of particular equilibriums that could be potentially considered in future studies.

Determinants of Export Performance of Ukrainian Firms

JEL Classification: *F14; P33*

Keywords: *Export activity; firm heterogeneity; Ukraine*

Abstract: Following the new strand in the new trade theory literature that focuses on firm heterogeneity in this paper we investigate determinants of firm export performance in Ukraine. The study is based on the BEEPS firm level data compiled by EBRD and the World Bank. The study covers the period starting in 2005 and ending in 2013. We estimate probit regressions for each year of our sample as well as for the pooled dataset that includes all years. Our pooled estimation results indicate that the probability of exporting is related to the level of productivity, the firm size, R&D expenditure, the share of university graduates in productive employment, as well as the internationalization of firms. The estimation results obtained for particular countries reveal some degree of heterogeneity. In particular, the firm age is significant only in the last years of our sample.

Introduction

After the collapse of the Soviet Union in 1991 Ukraine emerged as an independent country and followed its own way of economic transition from central planning to a market economy. This way was different from the path followed by Central and Eastern European (CEE) countries which radically liberalized their multilateral and regional trade and integrated successfully with the European Union. The scope of economic and trade

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

liberalization in Ukraine was significantly lower and structural and social reforms were less radical. This resulted in relatively poor economic performance compared to the transition countries which became member of the European Union in three waves of the Eastern Enlargement. As a result of increased integration with the EU firms from these countries gained the access to foreign markets and became the leaders in export activity among the post-transition countries. Given the economic success of these countries Ukraine changed its political orientation towards the West and signed the association agreement with the EU.

The main goal of this paper is to verify to which extent the Ukrainian firms are able to operate in the competitive market environment. In particular, we want to analyse whether the determinants of export performance of Ukrainian firms are similar to those of the firms from CEE countries that are the members of the EU. Therefore, in this paper we study empirically the relationship between labor productivity and exporting of Ukrainian firms, having controlled for other firm characteristics.

The majority of previous studies for Ukraine evaluating the effects of trade liberalization were traditionally based on aggregate trade flows data and gravity models (Movchan et al., 2010, Shepotylo, 2008, Nasadiuk, 2012). However, more recently the attention in the empirical trade literature has switched from the country-level to the firm-level determinants of successful export performance. This kind of empirical evidence for Ukraine is still missing.

Up to now the literature on Ukrainian enterprises based on analysis of firm-level data focused on determinants of long-term productivity. For example, Pivovarsky (2003) analyzed the impact of ownership concentration on the firm performance in Ukraine. Earle et al. (2014), using the panel of 7000 manufacturing enterprises, demonstrated that political favoritism, in the context of weak institutions, can have substantial redistributional impact on economic productivity. Kostenko (2014) confirmed that innovation activity had a positive impact on labor productivity of Ukrainian firms. Yemelyanova (2014) analyzed the impact of ownership structure on the effectiveness of Ukrainian enterprises. This paper contributes to the literature by analyzing the determinants of export performance of Ukrainian firms, focusing on the role of labor productivity.

In contrast to the international trade literature which assumed that firms are symmetric the recent strand in the new trade theory stresses the firm heterogeneity and its effect on export performance. This strand was initiated by Melitz (2003) and Helpman et al. (2004) who relaxed the key as-

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

sumption of the firm symmetry in the Krugman (1979, 1980) monopolistic competition model and introduced firm heterogeneity in terms of labor productivity. In the Melitz model (2003) model the relationship between the level of labor productivity and exporting was placed in the center of analysis. This model assumes that productivity differences are exogenously given and each firm has to pay fixed costs of entry into domestic and foreign markets. The model predicts that only the most productive firms with lowest marginal costs can cover the fixed cost of entry and become exporters.

A large number of empirical studies based on firm-level data compiled for many countries confirm the key prediction of the Melitz (2003) model, i.e. that more productive firms self-select into foreign markets. The existing empirical evidence shows that only a small fraction of the most productive firms are responsible for the majority of exports and most firms do not export at all concentrating their activities on domestic markets only.

The extensive summary of recent empirical evidence on the relationship between the productivity and export performance is provided by Wagner (2007, 2012). The importance of the firm productivity for exporting has also been emphasized by the EFIGE (2010) report. In this report it has been demonstrated that firm export performance in several EU countries depends on labor productivity and other firm characteristics. Unfortunately, these studies did not include the post-communist countries with the exception of Hungary.

Similar studies for CEE countries were initiated by Cieřlik, Michałek and Michałek (2012, 2013). In their most recent study, Cieřlik, Michałek and Michałek (2014) included in their analysis the Baltic, Caucasus and Visegrad countries. First, they estimated probit regressions for the pooled dataset that included all three groups of countries, and then they disaggregated the sample into particular country groups to study the differences and similarities between these groups of countries.

Their estimation results obtained for the whole sample indicated that the probability of exporting increases with the higher level of productivity and the measures of human capital, including the share of university graduates in total employment and spending on R&D activities. Moreover, the internationalization of the firms, proxied by the use of foreign technology licenses and the foreign ownership, was found to be positively related to the probability of exporting. Finally, they found that firm size was also a significant variable for the probability of exporting. These results were similar

to the results presented in the EFIGE (2010) report obtained for the firms from the large EU countries.

The estimation results obtained separately for specific country groups revealed a similar pattern in the case of the Visegrad countries and the Baltic states, although a smaller number of explanatory variables were statistically significant. However, in the case of the Caucasus countries only two explanatory variables were statistically significant: the firm size and the R&D variable, while the link between the level of productivity and the probability of exporting was not statistically significant. Thus, the firm size was the only explanatory variable which was statistically significant in the case of all groups of countries. This confirmed the importance of economies of scale for exporting.

Our study is based on the BEEPS firm-level data for the post-transition period starting in 2002 and ending in 2013. In our study we devote specific attention to the role of firm productivity as the main determinant of export performance. In addition, we study the role of other firm characteristics such as the role of foreign capital participation and the use of foreign technology.

The structure of this paper is as follows. In the next section we describe the empirical methodology. Subsequently, we discuss the properties of the dataset. Then we present our empirical results. In the final section we summarize and conclude.

Methodology of the research

In this study we analyse empirically the firm-level determinants of export decisions. In particular, we focus on estimating the theoretical relationship between firm-level productivity and exporting postulated by the Melitz (2003) model in Ukraine. This approach is an equivalent of studying the extensive margin effects. In other words, this means a positive effect on trade through an increase in the number of exporting firms or products exported.

In addition, we take into account other firm characteristics that may affect export performance such as the age and the size of the firm, the use of human capital proxied by R&D spending and the share of university graduates in total employment, as well as the role of foreign and state ownership.

To investigate empirically the relationship between labor productivity and exporting, postulated by the theory, we employ the probit regression, having controlled for the additional firm characteristics. We develop the

following empirical model to investigate the impact of individual firm characteristics on firm export performance. Let Y_i^* be our dependent variable indicating the export status of firm i . According to this model the export status of i -th firm can be related to the set of individual firm characteristics X in the following way:

$$Y_i^* = X_i\theta + \varepsilon_i \quad (1)$$

where the error term ε_i is independent of X_i which is a vector containing explanatory variables that affect exports with the first term equal to unity for all i , θ is the vector of parameters on these variables that needs to be estimated and ε_i is assumed to be normally distributed with a zero mean.

However, instead of observing the volume of exports for a particular firm, we observe only its export status described by the binary variable Y_i^* .

$$Y_i = \begin{cases} 1 & \text{if } Y_i^* > 0 \\ 0 & \text{if } Y_i^* = 0 \end{cases} \quad (2)$$

Hence, the probability whether a particular firm exports ($Y_i^* > 0$), expressed as a function of firm characteristics, can be written as follows:

$$\Pr(Y_i = 1 | X_i) = \Phi(X_i\theta) \quad (3)$$

where $\Phi(\cdot)$ denotes the standard normal cumulative distribution function (cdf).

Data Description

Our study is based on "Bank Business Environment and Enterprise Performance Survey (BEEPS)" data. This dataset is collected jointly by the World Bank and the European Bank for Reconstruction and Development. The main objective of the BEEPS survey is to obtain feedback from enterprises on the state of the private sector. The survey examines the quality of the business environment as determined by a wide range of interactions between firms and the state. The surveys cover manufacturing and services sectors and are representative of the variety of firms according to sector and location within each country. They cover the post-communist countries

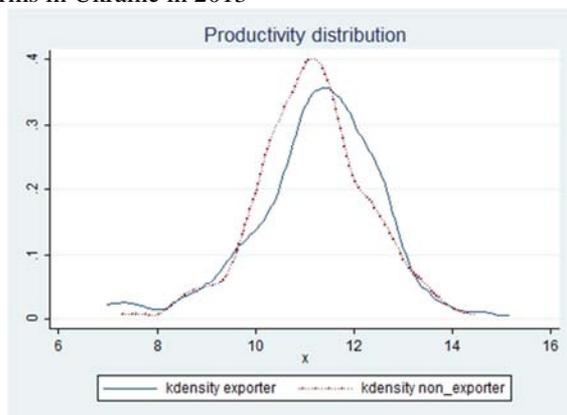

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

located in Europe and Central Asia (ECA) as well as Turkey. The data were collected for years 2002, 2005, 2009 and 2013.

Our study focuses on Ukraine which along with other Eastern European countries, with the exception of Russia, participates in the Eastern Partnership agreements. The Eastern Partnership works in the framework of the European Neighborhood Policy, which covers the EU's neighbors in the East and South. Moreover, Ukraine has recently signed the association agreement with the EU. This initiatives aim at tightening the relationship between Ukraine and the EU by deepening political co-operation and economic integration.

The export activity is defined as the situation when at least one percent of sales revenue of the firm comes from the sales made abroad. If we apply this benchmark about 20 percent of the analysed Ukrainian enterprises in 2013 were exporting. Data for Ukrainian enterprises for 2005, 2008 and 2013 show that on average exporters have larger productivity compared to non-exporters. On average mean of logarithm of output per full-time worker amounted to 10.11 for exporters and 9.36 for non-exporters in 2005-2013 period. The distribution of productivity in 2013, presented in the Graph 1, shows that the pattern of distribution was similar to that observed in the majority of the EU countries (EFIGE, 2010).

18-19 June 2015, Economics and Finance**

The key explanatory variables stressed by the Melitz (2003) model – labor productivity is expressed as the total amount of annual sales per full time employee (*productivity*). Other factors that may affect firm export performance include the level of innovation proxied by the R&D spending (*innovation*), the use of license from a foreign firm (*foreign_tech*), the use of imported materials (*import_mat*). We also control for the foreign ownership (*foreign_owned*) and private ownership (*private_owned*), as well as the age of the firm (*firm_age*) and the size of the firm (*firm_size*). In addition, we control for the effects of belonging to particular geographic region in Ukraine (*west, east, north, south and kyiv*) and individual time effects for particular years of our sample.

The detailed descriptions of firm characteristics used in our study are shown in Table 1.

Table 1. Description of variables used in empirical study

Variable Name	BEEP input Name	Description
Export	Based on the sum of d3b (direct exports as the share of total sales) and d3c (indirect exports as the share of total sales)	binary variable, that takes the value 1 if the establishment is exporting and 0 if not
Productivity1	Calculated as $\text{prod}=\log(\text{prod})$ $\text{prod}=\text{d2}/11$	logarithm of productivity expressed as total amount of annual sales per full time employee
Productivity2	Calculated as $\text{prodty2}=\log(\text{prodty2})$ $\text{Prodty2}=(\text{d2}-\text{n2a}-\text{n2e}-\text{n2f}-\text{n2b}-\text{n2ra}-\text{n2rb})/11$	Logarithm of productivity expressed as total amount of value added per full time employee
Firm_size	l1	Logarithm of no. of permanent, full-time employees of this firm at end of last fiscal year
Firm_age	Calculated as difference between the year of survey and year of firm's establishment	Logarithm of number of years since start of operations
Foreign_tech	Based on e6	binary variable, that takes the value 1 if the establishment uses technology licensed from a foreign-owned company and 0 otherwise*
Innovation	Based on h6	Binary variable, that takes the value 1 if the establishment is involved in innovation and 0 otherwise
Private owner-	Based on the sum of b2a	binary variable, that takes the value 1

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

ship	(share of capital owned by private domestic individuals) + b2b (share of capital owned by private foreign individuals)	if the establishment is fully private (both by domestic and foreign individuals) and 0 if the ownership is mixed with the state
Foreign ownership	Based on b2b	binary variable, that takes the value 1 if shares are owned by private foreign individuals, companies or organizations and 0 otherwise
Imp_Mat	Based on d12b	Logarithm of share of foreign material inputs or supplies in all material inputs and supplies

*For 2005 data foreign_tech indicates whether a firm obtained a technology license and for 2008 and 2013 dataset foreign_tech variable denotes whether a company obtained a license from a foreign-owned firm

Source: own estimations based on the BEEPS data.

In column (1) we display the estimation results for 2002 obtained from the specification that includes the labor productivity variable (*lprod*), having controlled for additional firm-level determinants of export activity mentioned in other studies. These include the size of the firm (*firm_size*), the age of the firm (*firm_age*), imported materials (*Imp_Mat*), the dummy variables for innovation (*innovation*), the use of foreign technology (*foreign_tech*), and the foreign ownership (*foreign_owned*). The dummy variable on private ownership was eliminated from the estimation due to the statistical insignificance of the estimator in various model specifications.

The estimated parameter on the labor productivity variable displays a positive sign but it is statistically significant only at the 10 per cent level. This result weakly confirms the link between the level of productivity and the probability of exporting predicted by the theory in the case of Ukraine. Moreover, the majority of our control variables are statistically significant. The exceptions are foreign ownership and firm age.

In column (2) we show the estimation results for 2005. These results are different from the results reported in column (1) in a number of ways. In

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

particular, the estimated parameter on the labor productivity variable is no longer statistically significant. The same applies to foreign technology and imported materials estimators. Moreover, the estimated parameter on the foreign ownership variable displays the expected positive sign and becomes statistically significant at the 5 per cent level.

In columns (3) and (4) we report the results for the most recent years 2008 and 2013 and in addition we control for the geographical location of firms. It turns out that the geographical location of firms is only weakly statistically significant in the case of 2008 and not significant in 2013. The estimated parameters on the remaining variables are statistically significant in both years with the exception of firm age which is not significant at all and innovation which is significant only in the most recent year 2013.

In column (5) we report estimation results based on the largest number of observations obtained from the pooled regression covering the period 2005-2013 and controlling for individual time effects by including time dummies for specific years. These results show that the productivity variable is statistically significant already at the 1 per cent level. This result confirms the major prediction of the theory regarding the link between firm productivity and exporting. All control variables are statistically significant, at least the 5 per cent of statistical significance, with the exception of the firm age variable. The sensitivity tests of based on the alternative measure of productivity are reported in Table 3 in the Appendix. These results confirm the existence of a positive link between productivity and exporting only for the most recent year of our sample.

Conclusions

In this paper we investigated the determinants of export activity of firms in Ukraine. The study was based on firm level data for the period starting in 2002 and ending in 2013. Our empirical results obtained for particular years revealed significant degree of heterogeneity among them. In particular, the estimation results indicate that the probability of exporting increases with the higher firm productivity, having controlled for other explanatory variables which is in line with predictions of the theory. However, this relationship is more pronounced in more recent years of our sample. This means the Ukrainian firms are becoming similar to the firms operating in Central and Eastern European countries that joined the European Union.

Moreover, the probability of exporting was positively related to a number of firm-level characteristics such as the firm size, foreign ownership,

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

the use of foreign technology, innovation and imported materials. These results allow us to formulate a number of policy recommendations for the development of the export promotion strategy for the Ukrainian authorities. In particular, the export competitiveness of Ukrainian firms can be improved by further liberalization and internationalization of the Ukrainian economy within the framework of the EU Association Agreement. In particular, this can be achieved by attracting more foreign direct investment, more intensive use of foreign technology and imported materials. Foreign direct investment can not only directly affect export performance of firms with the participation of foreign capital but can also generate the whole range of positive spillovers onto domestically-owned firms.

Mezzanine as an Alternative Form of Corporate Financing

JEL Classification: *G320*

Keywords: *Corporate Finance; Mezzanine Financing*

Abstract: The main goal of the article is the assessment of mezzanine financing as an innovative form in Poland, which might play a significant role in the dynamically developing companies which can't obtain sufficient capital from traditional sources in the form of bank credits. Mezzanine may be applied to: financing investment projects, increasing the value of the company, the expansion of businesses through mergers and acquisitions, redemption of shares or the financing of leveraged buyouts. The main methodology used in this article is explanatory research and comparative analysis. The hypothesis assumes that mezzanine financing may become an important alternative source of funding for medium and large sized enterprises in Poland.

This article presents the idea of mezzanine financing, its mechanism, structures and comparison to alternative funding, examples of such transactions costs. An important part is indication of types of mezzanine capital and applications in the USA, the UE including Poland as well as comparative analysis of advantages and disadvantages of mezzanine.

Introduction

Mezzanine financing can be a good and alternative form of effective financing of medium and big companies in Poland. It is a new form in our country and is worth popularizing. Financial sponsors will seek to use mezzanine capital in a leveraged buyout. Using mezzanine capital can potentially enhance the private equity of firm's investment returns. Especially, medium-sized companies may need a flexible, private mezzanine capital.

Mezzanine financing allows a company to raise money without selling more common stock and without issuing more corporate debt. This is done by combining the two in financial instruments which can be converted into corporate equity if the debt is not paid back within the specified period of time. This type of debt is also subordinated to the debt provided by senior lenders such as banks and venture capitalists (*Mezzanine Financing Example*, 2014). Mezzanine can be a flexible, effective form of corporate financing. However, it is usually more expensive than bank credits, but cheaper than other sources of capital, eg. the investor's own resources.

Methodology of the research

The methodology used in this article is the systematic, theoretical analysis of mezzanine financing and deductive method. First of all, it is explanatory research, which elaborates the relationships between study variables without knowing their final applications. It is conducted to show possible applications, costs and mechanisms. Moreover, it is comparative analysis of advantages and disadvantages of mezzanine financing.

The idea of mezzanine

Mezzanine financing is a hybrid between debt and equity financing. For instance, in the case of multi-tiered financing of an operation the sources of money will be senior debt, senior subordinated debt, subordinated debt, *mezzanine debt*, and finally the owner's own equity (*Mezzanine financing*, Encyclopedia, 2014). It is a type of debt financing whereby a company issues debt that the holders may convert into equity if the debt is not repaid in due course (*Mezzanine Financing*, Farlex Financial Dictionary, 2012).

Mezzanine financing is basically debt capital that gives the lender the rights to convert to an ownership or equity interest in the company if the loan is not paid back in time and in full. It is generally subordinated to debt

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

provided by senior lenders such as banks and venture capital companies. Since mezzanine financing is usually provided to the borrower very quickly with little due diligence on the part of the lender and little or no collateral on the part of the borrower, this type of financing is aggressively priced with the lender seeking a return in the 20-30% range (*Mezzanine Financing*, Investopedia US, 2014). This debt carries a high interest rate, as there is little or no collateral, but it is low-risk compared to other forms of debt financing because of its convertibility (*Mezzanine Financing*, Farlex Financial Dictionary, 2012).

Mezzanine financing is listed on a company's balance sheet as an asset; some companies use mezzanine financing because it makes it easier for them to obtain financing from other sources (*Mezzanine Financing*, Farlex Financial Dictionary, 2012). Mezzanine financing is advantageous because it is treated like equity on a company's balance sheet and may make it easier to obtain standard bank financing. To attract mezzanine financing, a company usually must demonstrate a track record in the industry with an established reputation and product, a history of profitability and a viable expansion plan for the business (*Mezzanine Financing*, Investopedia US, 2014). Mezzanine financings can be structured either as debt (typically an unsecured and subordinated note) or preferred stock.

Mezzanine financing is a loan to the owner with terms that subordinate the loan both to different levels of senior debt as well as to secured junior debt. But the mezzanine lender typically has a warrant (meaning a legal right fixed in writing) enabling them to convert the security into equity at a predetermined price per share if the loan is not paid on time or in full. Many variants exist, obviously, the most common is that some money is paid back as equity. Being unsecured and highly subordinated, mezzanine financing is very expensive, with lenders looking for 20% returns and up. Major sources of mezzanine financing include private investors, insurance companies, mutual funds, pension funds, and banks (*Mezzanine financing*, Encyclopedia, 2014).

The mezzanine mechanism

Financing programs or acquisitions by this mechanism typically involve some combination of lending by the source of money and provision of equity by the borrower. The special case is one in which the lender lends cash and gets a warrant to convert the loan, or a part of it, to stock either any time at the lender's option or in the case of partial or complete default.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

Chiefly, the following conditions prevail: a sum of money changes hands. Most of it is lent to the borrower at an interest rate but some of it is in the form of a favorable sale of equity. In addition, there may also be a warrant for the lender and restrictive covenants under which the lender is further protected. The loan will typically ensure an interest rate well above the prime rate and will be for a period of four to eight years (*Mezzanine financing*, Encyclopedia, 2014).

In the ideal case, the mezzanine financier anticipates earning a high interest on the loan and rapid appreciation of the equity they have acquired (or can acquire at a low price with the warrant). Mezzanine financing is typically used in acquisitions based on leveraged buyouts in which all of the investors, not least the mezzanine financier, anticipate cashing out by taking the business public again and refinancing it after the acquisition. Thus, the equity can be turned into cash with a substantial gain on the capital. In case of a failure, the mezzanine lender has little recourse except to influence the company's turnaround by using its stock acquired by means of the warrant. The borrower turns to mezzanine lenders because they cannot acquire capital by other means for lack of collateral or because their finances cannot attract less expensive lending. The price of the money, naturally, is high due to high rates of interest, but the owner is betting on being able to repay the loan without yielding too much control (*Mezzanine financing*, Encyclopedia, 2014).

Structures of mezzanine financing

Mezzanine financing can be completed through a variety of different structures based on the specific objectives of the transaction and the existing capital structure at the company. The basic forms used in most mezzanine financings are subordinated notes and preferred stock. Mezzanine lenders, typically a specialist of mezzanine investment funds, look for a certain rate of return they can receive.

Mezzanine contains characteristics of both debt and equity. As a loan instrument, mezzanine capital is ranked behind senior debt in terms of security and cash payments, both interest and principal. As a result, it will demand a higher return than senior debt (*Mezzanine capital*, Mezzanine Management Central Europe, 2008). Table 1. summarizes the basic characteristics of the three main types of financing.

Source: own study based on: (Ickiewicz J. 2004, 30; Trocki M. 2007, 22; Panfil M. 2008).

The costs of mezzanine

To provide a mezzanine security, the company and lender work together to avoid burdening the borrower with the full interest cost of such a loan. Because mezzanine lenders will seek a return of 14% to 20%, this return must be achieved by means of the other than simple cash interest¹ payments. As a result, by using equity ownership² and PIK interest³, the mezzanine lender effectively defers its compensation until the due date of the security or a change in the company control. Mezzanine lenders will also often charge an arrangement fee.

In addition to high interest rates, mezzanine lenders can convert their loan to equity or ownership if the company defaults on the loan. (*The Private Equity Book*, 2014, 69).

Although mezzanine financing costs are higher than bank credits, it may not largely burden the company. The part of the cost is paid by the company in the form of interest paid periodically or at the end of the funding period, whereas the rest - may be covered by the owners through the issuance of stock options or shares of the company (such as warrants) or other release to participate in profits of the company.

Applications and types of mezzanine capital

In leveraged buyouts, mezzanine capital is used in conjunction with other securities to fund the purchase price of the company being acquired. Usually, mezzanine capital is used to fill a financing gap between less expensive forms of financing (e.g. senior loans, second lien loan, high yield financings) and equity.

¹ *Cash interest* - a periodic payment of cash based on a percentage of the outstanding balance of the mezzanine financing. The interest rate can be either fixed throughout the term of the loan or can fluctuate (i.e. float) along with LIBOR or other base rates.

² *Equity Ownership* - along with the typical interest payment associated with debt, mezzanine capital will often include an equity stake in the form of attached warrants or a conversion feature similar to that of a convertible bond. The ownership component in mezzanine securities is almost always accompanied by either cash interest or PIK interest, and, in many cases, by both.

³ *PIK interest* - Payable in kind interest is a periodic form of payment in which the interest payment is not paid in cash but rather by increasing the principal amount by the amount of the interest (e.g., a \$100 million bond with an 8% PIK interest rate will have a balance of \$108 million at the end of the period, but will not pay any cash interest).

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

Mezzanine loans have three typical uses, according to a real estate attorney George Blackburne III (Baker M., 2014):

- The first one is to finance new construction projects, in the case of which the mezzanine loan supplements the loan from the commercial construction lender to lower the amount of money the developer must put up.
- The second use is for business owners with mortgage debt to gain access to capital when the terms or penalty of their mortgage prevents refinancing.
- The third use is a value-added deal, what means that investors can use mezzanine loans for property improvements, and because such improvements immediately increase a property's value, mezzanine lenders are willing to offer loans with a high loan-to-value ratio.

Mezzanine successfully are also used to (*Mezzanine – szansą dla przedsiębiorstwa*, mBank, 2013):

- support the expansion of the company through mergers and acquisitions,
- increasing the company's value before selling its shares on the stock exchange (IPO - Initial Public Offering or SPO - Secondary Public Offering),
- financing investments, which significantly affect the company's potential,
- repurchase shares from a shareholder who has decided to leave the company,
- financing leveraged buyouts (LBOs), including the company's buyout by managers (MBO - management buyout or MBI - management buy-in).

Mezzanine financing is used by business operators in both fast-growing and stable sectors, working in the markets of developing countries and developed countries. It is used by medium-sized companies, reaching revenues of tens of millions of PLN, as well as transnational giants, whose turnover is measured in billions of USD (*Mezzanine – szansą dla przedsiębiorstwa*, mBank, 2013). Mezzanine financing with loans are often used by private equity funds. They use debt instruments to significantly increase their return on investment and optimize investment risk. Entities that can receive mezzanine financing can be divided into two groups (*Komu mezzanine a komu nie...*, mBank, 2013):

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

- medium and big companies with a good financial standing, credit capacity which is not sufficient for the implementation of all investment plans,
- entities that intend to acquire companies in a good financial situation.

Mezzanine lending is a popular option for landlords, gas station owners, and virtually any other type of commercial property owner (Smith E., 2011). In real estate finance, mezzanine loans are often used by developers to secure supplementary financing for development projects (*Mezzanine Finance*, 2011).

The provider loans money on a second or even third mortgage basis and may either take an ownership interest in addition or may reserve the right to take over an ownership interest if the loan is not paid on time and in full. Because of the subordinate nature of the debt, the risky nature of the activities being funded by the money, and the lack of time to perform due diligence, mezz lenders usually want a high return on their money, in the 20 to 30 percent range (Evans D. L., Evans JD & O. W., JD, 2007).

Mezzanine lending dates back to the 1980s, when most providers were savings and loan associations and insurance companies, according to Bond Capital. Since then, many other types of players have entered the arena: limited partnerships, hedge funds, pension funds and leveraged public funds. Some banks also have established mezzanine lending practices (Baker M., 2014).

Originally developed in the North American market, mezzanine capital is an established finance instrument in the European capital markets. In Central and Eastern Europe, mezzanine capital has emerged from being a niche financing tool used in a limited number of deals to a mainstream, widely used form of leveraged finance and growth capital. In recent years the demand for mezzanine capital has seen a constant increase. Given its advantages as a financing tool including smaller size, lower structuring costs and higher flexibility, mezzanine has become a favourite subordinated debt instrument in Central and Eastern Europe (*Mezzanine capital*, Mezzanine Management Central Europe, 2008).

Mezzanine loans are complex, requiring heavy lifting by lenders who must sort through relevant property and entity documents. As such, lenders usually require mezzanine loans to have a principal of at least \$2 million, according to Katharine Noble of the law firm Jones, Waldo, Holbrook&McDonough. Lenders will also consider mezzanine loans only for large projects, usually at least \$10 million, according to Blackburne. About 150

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

mezzanine lenders operate in the United States alone as of 2010 (Baker M., 2014).

Typically, mezzanine financing is used for buyouts, recapitalizations, or acquisitions, and the amount of the debt often ranges from about \$5 million to \$25 million. Mezzanine debt also may incorporate stock warrants. Mezzanine financing may be used in the venture capital industry to describe a funding for a company that is beyond the start-up stage but is not yet ready for an initial public offering (*Mezzanine - Investment & Finance Definition*, 2010).

In 2008 mezzanine financing became an attractive alternative solution in the banking crisis as credit froze and obtaining loans became increasingly difficult. That largely explains why mezzanine debt was so popular over the last few years. (*The Private Equity Book*, p. 78).

In Poland, an international corporation Mezzanine Management (Poland) Sp. z o.o is specialized in these services. The examples of portfolio companies in Poland are: Lux-Med Sp. z o.o. - Warsaw (medical services), Solaris Bus and Coach S.A. - Bolechowo (production of buses), Zaberda S.A. - Wrocław (horizontal and vertical road signs) (*Mezzanine Management Poland Sp. z o.o.*, 2014). Moreover, mezzanine lending is mainly engaged in private equity funds (eg. Accession Mezzanine Capital - mezzanine fund⁴, Intermediate Capital Group). Banks such as mBank S.A. are beginning to come out with this offer.

The typical transactions, where mezzanine is used, financed by mBank include: transactions of mergers or acquisition, platform financing, replacement of the investor, recapitalization. mBank provides mezzanine for a period of 1 year to 7 years, and the amount of available financing in this form should be not less than PLN 5 million and not more than PLN 90 million (*Oferta mezzanine mBanku*, mBank, 2013).

⁴ AMC provided the loan with warrants of direct purchase shares or stocks in the following companies: Zaberda S.A., Lux-Med Sp. z o.o., Solaris Bus & Coach S.A.

Table 3. The pros and cons of mezzanine

Advantages	Disadvantages
<ul style="list-style-type: none"> • The owner rarely loses outright control of the company or its direction. Provided the company continues to grow and prosper, its owners are unlikely to encounter any interference from the mezzanine lender. • The method offers a lot of flexibility in shaping amortization schedules and the rules of borrowing on one's own, not least specifying special conditions for repayment. • Lenders willing to enter the world of mezzanine financing tend to be long-term investors rather than people expecting to make a fortune in a fast way. • Mezzanine lenders can provide valuable strategic assistance. • Mezzanine financing increases the value of stock held by existing shareholders although mezzanine equity will dilute the value of the stock. • Mezzanine financing provides business owners with the capital they need to acquire another business or expand into another production or market area. • Partner negotiations between the company and the financial institution can take a few weeks to finalize the financing transaction. • Mezzanine financing is cheaper than funding by the stock exchange. There are incurred advertising costs associated with the public distribution of shares, printing and publication of the prospectus, public charges, charging exchange fees, deposit and subsequent disclosure obligations. • In contrast to the funds acquired through the public market, there is no publicity obligations, detailed financial statements or the need to inform the public about the plans, events or prognoses of the company. The company can therefore pursue selected investment project, lead and implement the results of its own research and development activities or growth strategy without the need to inform about all other market participants including competition. 	<ul style="list-style-type: none"> • Mezzanine financing may involve loss of control over the business particularly if projections do not work out as envisioned or if the equity part of the borrowing is high enough to give the mezzanine lender a larger share. • Subordinated debt agreements may include restrictive covenants; which may include requirements that the borrower is not to borrow more money, refinance senior debt from traditional loans, or create additional security interests in the company's assets; covenants may also force the borrower to meet certain financial ratios - e.g. cash flow to equity. • Similarly, business owners who agree to mezzanine financing may be forced to accept restrictions in how they spend their money in certain areas, such as compensation of important personnel (in such instances, a business owner may not be able to offer above-market packages to current or prospective employees). In some cases, business owners have even been asked to take pay cuts themselves and/or limit dividend payouts. • Mezzanine financing is more expensive than traditional or senior debt arrangements. • Arranging for mezzanine financing can be an arduous, lengthy process. Most mezzanine deals will take at least three months to arrange, and many will take twice that long to complete. • Mezzanine capital is often a more expensive financing source for a company than secured debt or senior debt. The higher cost of capital associated with mezzanine financings is the result of it being an unsecured, subordinated (or junior) obligation in a company's capital structure (i.e., in the case of default, the mezzanine financing is only repaid after all senior obligations have been satisfied). • Mezzanine financings, which are usually private placements, are often used by smaller companies and may involve greater overall levels of leverage than issues in the high-yield market; as such, they involve additional risk. In compensation for the increased risk, mezzanine debt holders require a higher return for their investment than secured or more senior lenders.

In countries with developed capital market instruments, mezzanine diversity is the greatest (e.g. the United States, the United Kingdom, Germany). The most popular instrument of the mezzanine are subordinated loans (called junior debts), which are different from the usual loans (called senior debts) that the amounts of due are met in the final order in case of liquidation or bankruptcy of the debtor. These loans can also give the right (warrant) to purchase new shares or stocks. Another instrument for mezzanine are convertible bonds and bonds with warrants. In return for lower operating costs of the current bonds (lower the coupon or interest) the issuer allows to participate in equity, at the convertible bonds - conversion of bonds into shares - while the bonds with warrants - purchase of shares at a given price (Panfil M., 2008). In table 3. advantages and disadvantages are presented.

Conclusions

Mezzanine financings is the next stage of financing that follows venture capital financing, which can be completed through a variety of different structures based on the specific objectives of the transaction and the existing capital structure in place at the company. Mezzanine financing is advantageous, because on the balance sheet of a company it is treated like equity and may make it easier to obtain standard bank financing. It is typically used to finance the expansion of existing companies.

Additionally, mezzanine financings, which are usually private placements, are often used by medium companies and may involve greater overall levels of leverage than issues in the high-yield market; as such, they involve additional risk. Mezzanine financing is sometimes associated with leveraged buyouts.

Mezzanine loans are a risky but potentially high-yield way for lenders to provide established developers and business owners with capital. For borrowers, the loans provide a source of capital for new projects or expansions. They are a relatively new but quickly growing form of debt.

Mezzanine financing usually gives the lender the right to either ownership of the company or an equity interest in the company if the loan is not repaid. It is typically used by expanding companies that need money but don't want to go public and risk losing ownership of the company.

**World Trade and Regional Trade Orientation
in the Context of Forthcoming Transatlantic
Trade and Investment Partnership**

JEL Classification: *F14; F15*

Keywords: *international trade; the European Union; the United States; TTIP*

Abstract: We analyse potential consequences of the forthcoming Trade and Investment Partnership between the European Union and the United States (TTIP) for trade orientation of both partners. We do it with the short analysis of the characteristics of the third wave of regionalism and the TTIP position in this process as well as the dominant role of the EU and the U.S. in the world economy – especially – in the world trade. Next we study trade orientation of the hypothetical region created in result of TTIP. We use regional trade introversion index (RTII) to analyze trade between the EU and the U.S. that has taken place until now to get familiar with the potential changes caused by liberalization of trade between both partners. We analyze RTII for mutual trade of the EU and the U.S. than we apply disaggregated data to analyze and compare selected partial RTII (e.g. for trade in final and intermediate goods as well as goods produced in the main sectors of economy like agriculture or manufacturing).

Introduction

We analyse¹ potential consequences of the forthcoming Trade and Investment Partnership between the European Union and the United States (TTIP) for trade orientation of the region containing both partners. On one hand, we treat TTIP as a typical regional trading agreement (RTA) representing the third wave of regionalism (two geographically distant parties located on the different continents, the expected scope of the agreement going far beyond liberalisation of trade in goods). On the other hand, we acknowledge the parties' particular characteristics (both are among the strongest actors in the world economy and politics; both are centers). We see TTIP as the first approach of leading developed countries to cope with the growing economic and political power of developing countries (especially China, in this paper presented via APTA as China belongs to this RTA). We see TTIP as well as an initial agreement on the way of constructing RTA connecting the EU and NAFTA.

In this paper we analyse all RTAs with the constant number of members (number for year 2012). Consequently, we treat APTA as containing China over all analysed period. Moreover, we analyse the EU with 27 Member States. We name it without giving the number of participants and we are aware of the fact that the EU did not consist of members over the whole period of the analysis². However, 1999 (the starting year of this analysis and the year of the Euro Zone (EZ) establishment) all 27 states were tied at least with free trade area agreements (FTA). In some cases trade liberalization didn't cover "substantially all trade" as GATT/WTO stipulated. For example, in many cases agricultural products and other sensitive goods (such as textiles, chemicals) were at least partly excluded from free trade. Even if we take these facts into account, these 27 states started process of institutionalized integration long before they became members of the EU. It justifies the beginning of the empirical analysis in the time before their EU-membership.

The aim of this paper is to analyse the TTIP impact on international trade in the whole world as well as in both trading partners. We do it with

¹ Elzbieta Czarny's participation in this project is funded by National Science Centre of Poland on the basis of the decision No. DEC-2013/09/B/HS4/01488.

² In the first years of analysis the EU consisted in 15 Member States. The next 10 states (Cyprus, Czech Republic, Estonia, Hungary, Latvia, Lithuania, Malta, Poland, Slovakia and Slovenia) accessed the EU in May 2004. Bulgaria and Romania followed in 2007 completing the EU-27.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

the short analysis of the dominant role of both partners in the world economics and politics as well as of the characteristics of the third wave of regionalism and TTIP position in this process. We implement openness indexes of both trading partners to prove their involvement in international trade. Then we study trade orientation of the hypothetical region created in the result of TTIP. We use regional trade introversion index (RTII) to describe trade between the EU and the U.S. that has taken place until now and to get familiar with the potential changes caused by liberalization of trade between both partners in bilateral as well as in global trade streams. We analyze RTII for the whole mutual trade between the EU and the U.S. and we also apply disaggregated data to analyze and compare selected partial RTII (e.g. for trade in final and intermediate goods as in the BEC classification as well as in agricultural, manufactured and mineral products according to the SIC nomenclature). Our empirical analysis covers the period 1999–2012. For all analyses we apply the current prices. We point out that TTIP will be important not only for its participants but for the whole world economy.

Apart from methodological paragraph, the rest of the paper is organized as follows. Firstly, we analyse TTIP in the world economy as a part of the current (third) wave of regionalism. Secondly, we study economic potential and wealth of the EU, and – for comparison reason – of NAFTA and the selected other RTAs as well as of the U.S. to prove impact of TTIP on the further international economic co-operation. Thirdly, we analyze openness of both TTIP participants and regional trade orientation of the region created by the EU and the U.S. Conclusions complete our study.

Methodology of the research

In paper we use simple analysis of statistics and indexes concerning openness and regional trade orientation. Firstly, sum of export and import divided by GDP and is trade openness index. Secondly, we use the regional trade introversion index (RTII) first proposed by Iapadre (2006). This index allows measuring the relative intensity of regional trading versus trading with the outsiders. The RTII can range from –1 to 1 and is independent of the region's size as it applies relative values. Moreover, RTII is sensitive on the differences among the partners in one RTA. The relatively high values of this index are expected in the RTAs containing countries with the similar economic potential. If potential of the member states differs, the small partners can't reach trade intensity expected for the big ones and pull the index

down. The index rises (or falls) only if the intensity of intraregional trade grows more (or less) rapidly than that of extraregional trade. If the index is equal to zero, then the region's trade is geographically neutral (it grows similarly in the intraregional as well as in extraregional terms). If the index is a positive number, the region's trade has an intraregional bias (if $RTII = 1$, all region's trade is intraregional). If $RTII$ is less than zero, then the region's trade has an extraregional bias (if $RTII = -1$, all trade of the analyzed region is extraregional). The formula for the regional trade introversion index is:

$$RTII_i = (HI_i - HE_i) / (HI_i + HE_i)$$

$$HI_i = (T_{ii}/T_i) / (T_{oi}/T_o)$$

$$HE_i = (1 - (T_{ii}/T_i)) / (1 - (T_{oi}/T_o))$$

where:

T_{ii} = exports of region i to region i plus imports of region i from region i ,

T_i = total exports of region i to the world plus total imports of region i from the world,

T_{oi} = exports of region i to outsiders plus imports of region i from outsiders,

T_o = total exports of outsiders plus total imports of outsiders.

TTIP in the third wave of regionalism

TTIP is to be seen against the background of the progress of discriminatory liberalization of economic cooperation and the deadlock in the non-discriminatory negotiations within the World Trade Organization (WTO). Nowadays multilateral negotiations under auspices of WTO are more complex than in the past. The reason is growing number of the negotiations' participants. Moreover, the negotiations cover a broad range of subjects, including not only trade liberalization but also issues such as environment and intellectual property protection. They are accompanied by the conviction that, because of the expected benefits, the developed countries are predominantly interested in the adoption of further agreements, while the developing ones will suffer losses after their conclusion, at least in the form of the lack of potential profits. These objections became particularly loud after the successful conclusion of the Uruguay Round of GATT in 1995.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

As the prospects for global cooperation and success of the following round of multilateral negotiations are unclear, many countries and groups of countries are looking for alternative forms of international cooperation. The result is enhancement of regional integration allowing its participants to strengthen ties with their closest economic partners and to benefit without bearing costs of multicultural worldwide cooperation. Homogeneity of collective subjects of international relations (e.g. EU or NAFTA) helps to reduce internal transaction costs. Regional economic integration begins often in form of preferential (discriminatory) trade agreements concluded by the countries and groups of countries (more see Czarny et. al., 2010, pp. 126-128). All gains of economic integration are expected after the conclusion of TTIP as well.

The process of regional integration is called regionalism. It is defined as a process of uniting economic potentials of at least two countries/regions in order to maximise intensity of economic cooperation. The main symptom of regionalism is establishing regional groups of states and international organizations (within their competences). Members of these groups enjoy free internal trade as well as – eventually – free internal movement of production factors and economic policy coordination.

Of special interest are regional groups with participation of the WTO members. WTO member states are obliged to obey Organization's *acquis* (primary and secondary laws), including prohibition of discrimination as the foundation of multilateral trade system specified by the Most Favored Nation (MFN) and National Treatment (NT) clauses³. Basic rules of regional trading agreements are not compatible to the MFN and NT clauses. Preferences granted to the RTA's members are different from those enjoyed by the third parties⁴.

The first modern regional agreements were established within the normative scope of GATT Article XXIV already in the 1940's. RTAs have

³ Rules regarding MFN (for trade in goods as well as in services and copyrights) are covered by GATT Article I, GATS Article II and TRIPS Article IV. NT clause is regulated by GATT Article III, GATS Article XVII and TRIPS Article III.

⁴ Deviation from WTO general rules is permitted by GATT Article XXIV, agreements on interpretation of GATT Article XXIV, Enabling clause and GATS Article V. Article XXIV of GATT provides for free trade area (FTA) and customs union (CU) principles and regulates discriminatory liberalization of trade in goods. GATS Article V regulates international trade in services. The Enabling clause allows developed countries to enter RTAs and confer preferences in trade with developing countries. This clause makes it possible for developing countries to conclude agreements for intensification of their mutual trade.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

been booming during the current wave of regionalism started in 1995⁵ and lasting till today. Nowadays there are valid hundreds of binding bi- and multi-lateral RTAs⁶. As of 15 June 2014, some 585 notifications of RTAs (counting goods, services and accessions separately) had been received by the GATT/WTO. Of these, 379 were in force (see WTO, www.wto.org/english/tratop_e/region_e/region_e.htm accessed on 03.08.2014).

Initially regional agreements were of multilateral character. Currently bilateral agreements gain importance. They accounted for the majority all RTAs notified, in force and under negotiations (for the historical data see: Fiorentino et. al., 2009). In 2010 more than a half of RTAs in force (about 160 out of ca. 290) were bilateral (World Trade Report, 2011, p. 60). The basic reasons for the smaller popularity of the multilateral agreements are difficulties with their implementation arising from earlier political obligations of potential members who already accessed one or more RTAs.

In the past, mainly countries of the same geographical region (neighbouring countries) were those cooperating the most intensely, what was sanctioned in MFN clause. Gradually regional agreements have become the

⁵ Regional integration process taking place since the GATT establishment is referred to as the first wave of regionalism. In the second half of the 1980's started the second wave of regionalism (one of its main characteristics is participation of the U.S. in the process). The starting point of the third wave is the end of the Uruguay Round of GATT and the creation of the World Trade Organization in 1995.

⁶ In the real world RTAs have different forms. They vary from the least integrated PSAs to economic union. PSA (*Partial Scope Agreement*) can be concluded only by the developing countries. It provides only a partial elimination or decrease of tariffs, without obligation to full liberalization of trade in goods. FTA (*Free Trade Area*) consists in elimination of tariffs in trade with goods among the RTA members and keeping national tariffs of the member states against the third countries intact. In the framework of CU (*Customs Union*) tariffs among the members are eliminated as in a FTA and – additionally – a common tariff in trade with the third countries is introduced. In the WTO framework international trade in services is called “economic integration” (and this aspect of regional agreement is called *Economic Integration Agreement* – EIA). This name is justified with necessity of deeper integration in case of trade with services than of trade with goods. E.g. trade with services enforces presence of the foreign providers in the country and incorporates elements of international movement of production factors. Nevertheless the WTO meaning of “economic integration” is not a synonym of the full economic integration in the economic theory (see Balassa, 1961). EIA always accompanies FTA or CU. The next form of a RTA is *Common Market* (CM, the form of RTA not notified by the WTO). A CM has features of a CU supplemented by a free movement of production factors. More integrated economic union is a CM containing a harmonization and coordination of economic policies of the member states (if capital markets are liberalized, currencies of the member states are convertible and their exchange rates are fixed, there are conditions fulfilled for a monetary union, MU).

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

most important deviation from MFN. However, due to the exhaustion of the further possibility of the establishment of RTAs, during the first decade of XXI c. interregional forms of trade liberalization start to dominate. In 2010 about one half of RTAs in force (about 145 out of ca. 290) were not strictly “regional” and include countries from outside of the regions compatible with the geographical definitions commonly employed in the WTO context (World Trade Report, 2011, p. 60). Technological progress (especially in information transfer and exchange) supports the process of economic integration. Interregional groups help to further relax trade barriers and intensify international trade. Interregional agreements change the world trade pattern, which in the recent decades were primarily determined by intraregional exchange.

Transatlantic Trade and Investment Partnership is for some reasons a typical RTA of the third wave of regionalism. It will be concluded by two geographically distant parties located on different continents (one of them – the EU – is a collective entity). As in case of other RTAs, there are many economic and non-economic reasons of negotiating this agreement. The expected scope of this agreement will be going far beyond liberalisation of trade in goods. It will probably cover as well trade in services, movements of production factors (especially rules regulating flows of foreign investments and migrations), as well as environment and intellectual property protection.

Aware of typical characteristics of TTIP in the current wave of regionalism, we acknowledge its specificity derived from the parties’ particular characteristics. The EU as well as the U.S. are namely among the strongest actors in the world economy and politics. Both can be seen as the centers (and not – as very often in RTAs - one as a centre and another as a periphery). This is why, in case of TTIP conclusion, the standard Viner’s trade creation and trade diversion effects are expected as well as the terms of trade effect.

TTIP is aimed at deepening the economic ties between the EU and the U.S. It is an agreement that will significantly change the global balance of power. This agreement is seen to go far beyond a free trade area, which is most probably going to come into being by its notification by WTO. It will include free trade in services (EIA). Since it requires i.e. the presence of the service provider on the partner’s market and free movement of purchasers and producers of services, implementation of EIA entails deeper connections of partners’ economies than in the case of a FTA.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

The working name for the forthcoming EU – U.S. agreement, Transatlantic Trade and Investment Partnership is indicating its broader range than this of a FTA as well. Moreover, judging by already finished negotiations on the RTAs created by the EU and Canada, as well as by other selected RTAs concluded by the EU and the U.S. (particularly those with developed countries), one can assume that TTIP will cover not only principles of liberalization of trade with goods. In addition to the reduction of tariffs the TTIP will regulate: elimination of non-tariff barriers to trade, free trade in services and rules for foreign investment regime, public procurement, protection of intellectual property rights, and ways of dispute settlement. TTIP will presumably be a model for subsequent RTAs. It is especially feasible in the area of technical standards applying to products. It can also significantly affect the fate of multilateral liberalization negotiations under WTO bringing about either some ready-made solutions or at least an incentive for discussion.

TTIP negotiations are underway⁷. The first round was concluded in July 2013. It was aimed at defining the full range of topics that EU and the U.S. intend to cover in the TTIP. In November 2013 during the second round of negotiations liberalization of trade in services, energy and natural resources, and protection of foreign investments were discussed⁸.

On 20th December 2013 the third round of TTIP negotiations in Washington has been finished. The talks concerning parties' expectations as to the access to services markets and systems of mutual protection of foreign investments were continued. An American model of a bilateral agreement on mutual protection of investments (BIT, *Bilateral Investment Treaty*)⁹ was analyzed which was applied in the agreement constituting the NAFTA, as well as the experience pertaining to the mechanism of dispute settlement

⁷ For details, see Czarny et. al., 2014.

⁸ The second round of negotiations took place with a delay due to the fiscal paralysis the U.S. administration. This demonstrates the sensitivity of the negotiations to the internal problems of the parties. At the same time, the deterioration of the U.S.-Germany (and partly even U.S.-the rest of Europe) relations as the consequence of the phone hacking scandal didn't change the negotiations agenda.

⁹ In view of the absence of more universal regulations, the protection of foreign investments is regulated by bilateral agreements (BITs). There are usually two model solutions accepted, which originate from different principles, although they bring forth identical practice. In the first case, the state authorities of a country concluding a BIT commit themselves to promote the tendency of investors from the partner country to invest in its territory. In the second model, the state authorities leave the contracting parties the right to specify the terms of the contract, unless they violate the law. For more information see Czarny& Menkes, 2008.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

within it (though as to the questions concerning the ISDS (*Investor-State Dispute Settlement*) the EU position is constantly changing). There had been also regulatory problems studied, including the EU model of technical barriers to trade. Progress in talks on the automotive sector was achieved. Contentious issues were: equal access of European firms to public procurement in various states in the U.S., and regulations on agriculture in the part of the U.S. In this latter case the disparities arise mainly from the different nature of agricultural production in the EU and the U.S., as well as from different approaches to genetically modified products (GMO, *Genetically Modified Organisms*). During the fourth round taking place in March 2014 negotiations concerning three main issues (market access, regulations and rules) were continued. The fifth round of negotiations (May 2014) focused mainly on technical barriers of trade, access to the market for agricultural products and rules of origin. During the sixth round of negotiations (July 2014) the U.S. and the EU leaders have set a timetable for completing an agreement for TTIP by late 2014 (what seems not to be realistic).

**Economic potential and wealth of the EU, the U.S., NAFTA
and other selected RTAs**

The empirical analysis on TTIP is started by comparing GDP and GDP *per capita* (GDP *pc*) of the EU and the U.S. as well as NAFTA and two other RTAs selected as the best in the year 2012 among the multilateral RTAs (the sample excludes the EU and NAFTA)¹⁰ - Tables 1 and 2 (the same criterion is applied in Table 3).

Among all RTAs NAFTA and the EU have the biggest economic potential, although they experienced relatively low growth rates of GDP (ca. 1.8 times during the period 1999-2012). NAFTA's economy is bigger than the EU economy in all analyzed years apart from the years 2007-2009 (the last economic crisis)¹¹. Till 2003 even the U.S. economy was bigger than the

¹⁰ The RTAs analyzed in tables 1-3 names are (if the name does not reveal the location of the RTA or gives it not precisely we add this information – according to WTO – in brackets): AFTA (ASEAN Free Trade Area located in East Asia), ANZCERTA (Australia New Zealand Closer Economic Relations Trade Agreement), APTA (Asia-Pacific Trade Agreement, East and West Asia), EFTA (European Free Trade Association), EU (European Union), GCC (Gulf Cooperation Council, Middle East), LAIA (Latin American Integration Association, Nord and South America, The Caribbean), NAFTA (North American Free Trade Agreement)

¹¹ The economic crisis becoming global in the autumn 2008 has started in the U.S. economy earlier, what had considerably affected the NAFTA's economy.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?

economy of the EU as a sum of 27 Member States. Since then both economies have had a similar size with a small prevalence of the EU.

Table 1. Gross Domestic Product of the EU, NAFTA, the U.S, APTA and LAIA in the years 1999-2012 (current prices and exchange rates, trillions USD)

Year	EU	NAFTA	US	APTA	LAIA	World
1999	9.15	10.55	9.37	2.08	1.82	31.95
2000	8.48	11.33	9.97	2.26	2.01	32.86

The dominant position of the EU and the U.S. economy is shown by comparison with two RTAs positioned in the ranking just behind the leaders (APTA and LAIA). In 1999 APTA's GDP was ca. 5.1 times smaller than NAFTA's GDP and 4.4 times smaller than GDP of the EU. In 2012 this difference was equal – respectively – 1.65 and ca. 1.5 times. These figures are an appropriate measure of the progress made by the APTA's economy. For LAIA the respective figures are ca. 5.8 and 5 times in 1999, and 3.45 and 3.1 in 2012.

Despite the rapid increase in GDP of APTA (more than 5.4 times during 14 analyzed years) its huge population makes it still poor. Because of the relatively low GDP *pc* it is similar rather to the RTAs containing developing countries (for example the other Asian or African RTAs) than to any developed group. In 1999 the richest among RTAs was the population of

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

EFTA with GDP *pc* almost 2 times higher than the EU (the 3. position in the ranking) and 1.5 times higher than the 2. in the ranking NAFTA (Table 2).

Table 2. Gross Domestic Product *per capita* of the EU, NAFTA, the U.S, EFTA and ANZCERTA in the years 1999-2012 (current prices and exchange rates, thousands USD)

Year	EU	NAFTA	U.S.	EFTA	ANZCERTA	World

In 2012 NAFTA became the third richest RTA after the ANZCERTA's GDP *pc* jumped to the level 1.6 times higher than this of NAFTA. In the period 1999-2012 ANZCERTA experienced increase of GDP *pc* ca. 3 times. During the analyzed period the U.S. population is richer than the people in the EU (as well as in NAFTA).

Analysis of GDP and GDP *pc* revealed that the EU and NAFTA dominate among the RTAs as well as in the world economy. The same can be said about the U.S. being the leading economy in NAFTA (in 1999 the U.S. economy produced almost 90% of the NAFTA's GDP; in 2012 it was still

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

equal to ca. 84%). RTA containing the EU and the U.S.¹² will create a new superpower in the world economy. In 1999, the U.S. and the EU joint production was equal to almost 60% of the world GDP. Their export exceed 53% of the global export. At the beginning of the second decade of the XXI c., the position of both partners in the global economy is worse than at the end of the XX c. In 2012, the common share of the EU and the U.S. in the world GDP amounted to 44.5%, whereas the export of both partners does not exceed 40% of the world export¹³ (see UNCTAD, <http://unctadstat.unctad.org/> accessed on 03.08.2014).

Openness and trade orientation

Both TTIP partners differ in intensity of their trade with the outside world as well as with the member countries of the RTAs they belong to (intra EU-trade and intra-NAFTA trade). We measure intensity of trade as a sum of export and import divided by GDP and treat the calculated numbers as trade openness index (Table 3).

During 1999-2012 an increase in openness of all analyzed RTAs but AFTA is noticeable. Two Asian blocs (AFTA and GCC) have an openness index bigger than 1. It means that their shares in the world trade are bigger than their shares in the global GDP. In case of AFTA trade has outstripped its GDP nonstop since 1998 (see Czarny & Folfas, 2014). For GCC it holds in the last two years and in 2008. The EU achieved considerably higher values of the trade openness indexes than NAFTA: in 2012 – respectively – 0.7 and 0.3 (the difference between both indexes is increasing in time), though we can observe increasing openness of both of them. The relatively low openness indexes of NAFTA are understandable as this RTA contains two big economies concentrating on supplying their own internal markets (we can see this comparing the NAFTA openness index with the one of the U.S.).

¹² In the further part of this paper we refer to the hypothetical region created after the conclusion of the TTIP and containing the EU and the U.S. as to „the TTIP region”.

¹³ If TTIP was introduction to FTA between the EU and NAFTA, the new bloc EU plus NAFTA would account for 48.5% of global GDP (2012) and for 44.5% of world exports (2012).

In this paper we compare RTII indexes of the region created by the EU and the U.S. after conclusion of the TTIP agreement (TTIP region) with the respective indexes of the EU (containing 27 Member States) and NAFTA. This analysis covers the years 1999-2012. Firstly, we analyze regional trade introversion index for trade in all commodities (Table 4). Secondly, we discuss RTIIs calculated for the disaggregated groups of goods. We start with the division into the final (Table 5) and the intermediate goods (Table 6) compatible with the BEC nomenclature. Further we proceed to RTII calculation for the main sectors of the economy (SIC nomenclature¹⁴). We

¹⁴ According to SIC nomenclature the economies are divided into:

- agriculture, forestry and fishery products,
- mineral commodities (metallic ores and concentrates, coal and lignite, crude petroleum and natural gas, nonmetallic minerals, except fuels),
- manufactured commodities (food and kindred products, tobacco manufactures, textile mill products, apparel and related products, lumber and wood products, except furniture,

**Proceedings of the 8th International Conference on Applied Economics

18-19 June 2015, Economics and Finance**

begin with the RTII for trade in agriculture, forestry and fishery products (Table 7), because the first part of this category is important for export of the TTIP partners and is heavily protected by both of them. Then we analyze RTII of the manufactured goods, which are very important in trade between developed countries. This sector is divided into two subsectors: the first one consists in defined manufactures (Table 8) and the second one in manufactures not defined by a kind (Table 9). We continue analyzing RTII in trade with mineral products (Table 10). For sake of completeness of the analysis we add (though not extensively comment) data on the RTII for trade in other commodities (Table 11). We use data extracted from WITS-COMTRADE database.

The EU's and NAFTA's trade has similar, relatively high intraregional orientation, though in the EU it is decreasing whereas in NAFTA increasing. This result is opposite to the one achieved in the analysis of the TTIP region. Calculating RTII for this region including intra-EU trade we get positive and increasing though relatively low values of the index. They have been permanently lower than 50% of the respective RTIIs for NAFTA and the EU (except for 2011, when it was slightly higher than 50% of NAFTA's RTII). If, however, we take into account that this result is heavily biased because of a very intensive trade among the EU-members, it means, if we acknowledge that the intra-EU trade no longer can be seen as international trade because of the depth of the partners' economic integration, we get strong and growing (in absolute value) extraregional trade (since 2003 the numbers are almost the same as for the TTIP region with intra-EU trade but have opposite sign). For the first glance this result can be seen as a proof of economic incompatibility of the EU and the U.S. However, it is not surprising and can be seen as a confirmation of effectiveness of the trade barriers discouraging UE-U.S. trade. One can expect a considerable intensification of the turnover between TTIP-partners resulting from liberalization of their mutual trade. This analysis confirms rather necessity

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

to work on trade liberalization, if these partners intend to intensify their trade (it is especially visible in the further part of this analysis concerning trade in agricultural products in Table 7).

More precise approach to trade orientation of the TTIP region we provide with the analysis of partial RTIIs calculated for groups of commodities. In trade with final goods the EU is permanently more intraregional oriented than NAFTA. In the first years of the analysis (till 2002) EU-RTII for trade in final goods was even more intraregional oriented than trade in all commodities. Such high values of the EU-RTII can be explained with the similarity of countries constituting the European Union. They have similar GDP *pc* as well as similar culture, tastes and – to some extent – even climate. In effect, the EU-population has similar consumption pattern, what means that the firms are producing similar goods and demanding similar equipment. As these countries are the developed ones, they produce similar goods (e.g. manufactures) as well. It means, that in both consumption and production goods there is a big potential for the mutual trade among the Member States (this is visible by studying EU-RTII for manufactured goods in Table 8 as well). This result is confirmed, when we compare the EU-RTIIs with the respective RTIIs of NAFTA consisting in very differentiated members and having lower RTIIs. In this context the TTIP region (in all analyzed years for mutual trade without the intra-EU trade and in the years 1999-2003 even for the EU-U.S. trade including the intra-EU trade streams) appears even more extraregionally oriented than in case of trade with all goods. This region has the negative RTII in the years 1999-2003 even if we include intra-EU trade. However, tendency to its growth is noticeable. Moreover, the absolute values of the index for the TTIP region without intra-EU trade are bigger than of the RTIIs for all commodities. In this case intensification of intra-industry trade¹⁵ can be expected. This is the best chance for the competitors from the EU and the U.S. producing similar (especially technologically advanced) products to find segments of markets to be supplied with their products.

¹⁵ Intra-industry trade is a simultaneous export and import of similar goods produced in the same industry in bilateral turnover.

The RTII for trade in the final goods had tendency to fall in both the EU and NAFTA, whereas in the TTIP region with the intra-EU trade these RTIIs were rising (till 2011), though in the first years of the analysis (till 2003) they were extraregionally biased with the weaker and weaker bias. In this case of importance is production of multinational enterprises (MNEs) located by both TTIP parties as well as – more general international production fragmentation. This time as well the TTIP region was strongly influenced by the internal EU-trade. If we exclude the intra-EU trade and calculate the RTII only for the EU-trade with the rest of the world, this orientation stays extraregional and relatively stable.

Impact of MNE's, production fragmentation and supply chains is even more visible if we analyze regional orientation of intra-TTIP region's trade though regional trade introversion indexes for trade in intermediaries as well as the concrete figures show the tendency different than these for the final goods. RTII for the intermediaries is higher in the case of the EU than in the case of NAFTA, because the EU participates in more production nets, whereas NAFTA's international production is mainly concentrated on two of three member states (the U.S. and Mexico). The TTIP region with intra-EU trade has relatively high and growing positive values of RTII (ex-

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

actly as the one of the EU), what proves its intra-regional orientation. The values of RTII for trade in intermediaries doubled in the analyzed period though even in 1999 this index was almost two times higher than the RTII for all commodities. For the TTIP region without intra-EU trade RTII was relatively low in absolute terms. This confirms relatively poor protection of intermediaries applied by both TTIP-partners and is compatible with general observation that production of intermediaries is usually less protected than the average of the economy (with the aim of development of the local production of the final goods with the use of imported intermediaries).

The RTII values for the single groups of products differ between sectors. The effects of protection are especially visible if we analyze trade in agricultural products, which is the most protected part of the EU economy and is strongly protected by the U.S. too (Table 7). The EU, as expected, has much higher RTIIs than NAFTA and the EU's RTII for agricultural products is the highest one in our analysis. In this case relatively low NAFTA's RTII values result from the different economic potentials of the U.S. and the other members of this RTA. The huge U.S. production can

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

hardly be absorbed by the smaller market of Canada and the poorer population of Mexico, which develops its own agricultural production.

As far as TTIP region is concerned, especially without the intra-EU trade, the figures are very high and negative. Trade of the TTIP region appears very extra-regionally oriented. This is mainly the result of the EU-common agricultural policy as well as of the U.S. protection. In this case, however, one cannot expect a very quick and large change even after the signing of the TTIP agreement as some exceptions will surely remain.

RTII in trade with manufactured goods (Table 8) in the TTIP region with intra-EU trade has high and growing values. In 2012 it made up 0.6 of the EU's RTII and 0.67 of the NAFTA's RTII. In the TTIP region without intra-EU trade, RTII still had negative values, though they are low in absolute terms. This is the result of a poor protection of these goods. It is not only the effect of the EU or the U.S. economic policies, but mainly of the non-discriminatory trade liberalization in the framework of GATT/WTO.

For manufactured goods not identified by kind the RTII figures are lower than in manufactured goods presented in the Table 8 for the EU and the TTIP region with intra-EU trade and higher. It was increasing till 2011 in

case of NAFTA (Table 9). For the TTIP region without intra-EU trade the figures are as usually negative and higher (in absolute value) than for the identified manufactures.

Analysis of RTII for trade with mineral products reveals the next difference between the TTIP partners (Table 10). The EU is poor in raw materials' poor, what results in the lowest among all RTIIs calculated for the EU and NAFTA. On the contrary NAFTA (and its dominant member the U.S.) is abundant in these products. This justifies the fact that the EU is trading with mineral products much more intensively with the rest of the world than NAFTA and is trading less intensively intra-regionally. NAFTA's RTII values for trade in these products are almost two times higher than these of the EU. The raw materials scarcity of the EU decides also about the negative signs of the TTIP's RTIIs (even in the version with intra-EU trade). We cannot expect intensification of mutual trade with these goods as the EU is set to import mineral products. The U.S. in turn is a good candidate for the supplier of raw materials, however it surely exports rather processed intermediaries (what was visible by the analysis of the TTIP's trade in the intermediaries).

Conclusions

We prove that TTIP will be a typical RTA compatible with the standard of the third wave of regionalism as it will connect two geographically distant parties located on different continents and its expected scope will go far beyond liberalisation of trade with goods. Simultaneously we acknowledge the particular characteristics of TTIP parties what makes TTIP a very special RTA. The EU and the U.S. are among the strongest actors in the world economy and politics. Both are centers. The result is an importance of the TTIP for the whole global economy.

Analysing the characteristics of both TTIP partners we stated that the EU is much more open than the U.S. It is understandable as the EU is a collective entity consisting of relatively small but rich national economies forced to import for ensuring themselves foreign goods (e.g. raw materials) and to export goods produced with technologies characterized by increasing returns to scale (e.g. manufactures). On the contrary, the U.S. is a large economy concentrated on supplying domestic market.

The analysis of the TTIP region's orientation of trade based on the historical data from the period 1999-2012 revealed several conclusions. Nowadays trade between the EU and the U.S. is constrained by the protection applied by both partners. Trade liberalization constituting one necessary part of TTIP will surely help to intensify this trade. Of special concern is trade with agricultural products which is most constrained and hardly will be fully liberalized even in a framework of TTIP. Simultaneously, both parties are even now trading relatively intensively with intermediaries, which are often less protected than the average of the economy for the sake of development of final goods' production. The manufactured goods are as well relatively often traded, mainly in consequence of their poor protection after many successful liberalization steps in the framework of GATT/WTO.

The creation of the TTIP region will certainly intensify mutual trade of the EU and the U.S. both inter-industry (e.g. mineral products for manufactures) and intra-industry one (e.g. with manufactures). Consequently, we point out that in many respects the TTIP will be important not only for its participants but for the whole world economy as well. TTIP appears to be an economic and political project with serious consequences for the world economy and politics.

Choice Overload Paradox and Public Policy Design. The Case of Swedish Pension System

JEL Classification: *D19, H44, H55*

Keywords: *extensive choice; cognitive limitations; market failure; choice architecture; funded pensions*

Abstract: In this paper we focus on an adverse effect of extensive choice widely known as ‘choice overload’. We draw on the case of Swedish funded pensions for illustration and analyze consequences of the design that allowed for maximizing the choice set. The analysis shows limitations of employing the rational choice approach to the real choice decisions biased with common psychological factors and demonstrates that government’s responsibility for the privatized pension system does not end with the design. We also emphasize the need for a decent default option, which would mitigate socially harmful results of adverse behavior effects like procrastination, status quo bias or abstaining from choice. After all, privatized pension systems still belong to a sphere of public policy.

Introduction

Decisions of choice are one of the key issues of economics. Sound choices contribute to increased welfare of groups and individuals, determine efficiency of economic endeavors and are essential for society’s long-term economic development. In psychological terms enjoying the possibility of choice provides a sense of personal control over one’s life and fuels intrinsic motivation for purposeful actions leading to increased task enjoy-

Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

ment and performance. The choice itself reassures our perception of environment control and self-efficacy stemming from our very biological condition (Leotti et al. 2010). Many choice options are thus usually presumed to be desirable and beneficial. Yet as recent literature suggests, this belief has serious limitations. An overabundance of choice possibilities can lead to adverse effects both in consumption decisions and life satisfaction (Schwartz 2004). In contrast, constraints imposed on choice sets facilitate the process of decision making and increase subsequent satisfaction.

This choice dialectics had seemed so far rather detached from public sphere as the state usually provided beneficiaries of public policies with very limited choice compared to the amount of goods and services offered by markets. However, the recent turn in welfare policies assumed that they should become more choice oriented just like critics of public monopolies and standardization demanded. This way what seemed to be an exclusive issue of consumer choice and marketing strategies entered the arena of public policy (see Lynch and Zauberman 2006). As a result the questions of 'choice architecture' have become increasingly important as well as the need of rethinking government's role and responsibility when it comes to designing public policies of marketized welfare state (Thaler and Sunstein 2009).

This paper aims at broadening our understanding of the choice overload phenomenon by examining the case of Swedish pension system. It illustrates the fact that privatization of public sphere brings not only benefits, but also market failures that used to be addressed by traditional welfare states. We also show the shortcomings of employing the principles of rational choice into real world situations like the choice architecture of pension savings system. On this background we point to the consequences of this phenomenon being cast on government's role and responsibility in a democratic state.

The paper is organized as follows. Second section provides brief information on the methodology of research. Third section reviews the latest literature on choice overload sketching the current state of the art. Third section discusses the question of choice in modern welfare state policies focusing on pension systems. Fourth section presents shortly the general design of the Swedish pension reform. Fifth section scrutinizes on the Swedish premium pension system and observed overload effect. Final section concludes.

The methodology of the research

The methodology of this research draws both on literature study and data analysis which is reflected in the paper's structure. Theoretical sections review the latest literature on the choice overload effect published mainly in journals committed to consumer research and psychology of economic agents. This way the model of *homo economicus*, which is usually employed in economics, can be contrasted with empirical research coming from outside pure economics. The subsequent discussion on introducing choice into public policies is based on this approach as well.

The sections devoted to the Swedish case of premium pensions draw on empirical material. We use the latest data published by the Swedish Pension Authority which include data statistics to be found on Authority's webpage (www.pensionsmyndigheten.se) and official publications on pensions (inter alia annual pension reports named *Premiepensionen – Pensionsspararna och pensionärerna*). Unfortunately since 2012 the annual reports are published in shorter form and thus some data is missing. We also make use of official government reports and directives evaluating the performance of the pension system and recommending desirable changes therein.

Choice overload and the limits of *homo economicus*

The standard economic model of rational choice is based on a number of simplifying assumptions (see for example Schotter 2009). Economic agent is, for example, aware of all of the choice options that are available to him and displays no cognitive limitations in processing and ordering them. Driven by expected utility maximization he takes decision that are *always* optimal given existing constraints. His preferences are stable and do not depend on context. Being a self-oriented actor, he does not take into consideration utility of others nor existing social structures. However, this view of an economic agent, a fictional character usually referred to as the model of *homo economicus*, is an abstract construction designed for a specific kind of scientific reasoning, preferably to be employed in formal modeling, and modern economics is rather well aware of this caveat (O'Boyle 2007; Thaler 2000). As a matter of fact, a whole branch of economic science – behavioral economics – has been developed in order to trace the inconsistencies of this model with respect to reality searching why people behave differently from what the model predicts and what it means for economic

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

theory and praxis (see Wilkinson 2008 for a comprehensive introductory text). So even though some scholars argue that models of rational choice are nowadays flexible enough to incorporate the critical insights and still prove to be useful in explaining economic phenomena (Gilboa 2010), one has to be aware of their limitations for they were not designed to reflect the reality of human nature, but for the sake of particular scientific cognition.

An example of phenomenon that the theory of rational choice fails to explain is the situation in which an agent faces excessive choice options which actually deter him from making an informed and rewarding choice. In effect, he does not maximize his utility, because he falls short of being a perfect calculating machine. This stands in opposition to the claim that a large number of options to choose from contributes to an increased welfare of individuals. Following the logic of standard economic model, for a numerous population of individuals holding various preferences, the greater set of choice, the better. In this situation each and every individual has the possibility to examine the choice set for himself and choose an option that fits him best leading in aggregate terms to the lowest general welfare loss possible. Preferences of most people are met and thus the highest utility for all is achieved. The relation between preferences, choices and individual welfare is, however, not so straightforward. First, satisfaction of interests does not have to imply increased welfare (Hausman 2012). And second, individuals facing extensive number of options have lowered motivation to choose and achieve lower level of contentment than previously expected. More choice does not have to automatically imply that people will be better-off with it (Botti and Iyengar 2006).

Recent literature has grouped negative effects of choosing from an extensive number of options under term 'choice overload'. These effects usually include abstaining from making a choice decision, lower satisfaction derived from one's choice and feeling of regret after making a choice. The choice overload paradox has originally derived from consumer research. In a seminal paper Iyengar and Lepper (2000) reported findings of three experimental studies in which participants made choices from a differentiated sets of choice options. They found that too much choice was a negative factor in choosing and buying products. While at first vast array of choice seemed attractive and desirable, it turned detrimental for actual behavior and decision making. Participants made more confident decisions when their choice was limited: they felt more inclined to purchase items, reported higher satisfaction from the decision made, and performed better with tasks chosen from a limited set of possibilities. Too much choice, on the other

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

hand, caused decision paralysis, poor decision quality and feelings of regret due to rising opportunity costs and escalation of expectations. The feelings of regret were confirmed in the studies of Sagi and Friedland (2007) who found that regret is positively related with rising number of alternatives and their diversity and of Haynes (2009) who observed that larger set of alternatives led to decreasing satisfaction from the choices made. A number of adverse effects of choice overload was also found by Vohs et al. (2008) who demonstrated that choosing among many alternatives is effortful and depletes cognitive resources leading to deterioration in self-control, stamina and pain tolerance, persistence in the face of failure, and performance in numerical calculations.

A number of earlier studies was also very critical of the rationality assumption employed by conventional models of choice, because people's ability to process information is limited and results either in third party influenced choice or in abstaining from choice. Tversky and Shafir (1992) challenged the idea that each alternative is assigned a value so that individual can choose the one with the highest rating. In the situation of conflict among the alternatives, one rather tends to defer decision, search for new alternatives, or choose the default option. Dhar (1997) confirmed these findings stressing the fact that small differences in alternatives between options increase the preference for a no-choice option. Timmermans (1993) found that when faced with increasing number of alternatives, people tend to assimilate less information on the attributes of offered options and to adopt absolute rather than relative comparisons due to the inability to process such an amount of information¹. It has also been convincingly argued on philosophical grounds that rational choice theory works best when choice is seriously constrained (Satz and Ferejohn 1994). Agents' preferences are not a matter of individual psychology and cognition, but they rather stem from social structures and interests.

When faced with overwhelming choice people tend to defer choice explicitly. Dhar (1997) for example found that expansion of the choice set even by adding more attractive alternatives actually drove people into the no-choice option. Also, when asked to point to the features of alternatives that appeared attractive to choice makers, participants felt discouraged from committing to a firm decision. However, the possibility to choose more than one option increasingly mitigated the effect. A study by Jessup et al. (2009) identified two factors that fostered no-choice decisions. First, people

¹ However, when it comes to comparing interpersonal well-being, it is the relative standing that counts, not the absolute one (Solnick and Hemenway 1998).

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

avoid choice when their preferred option changes too often. And second, when time runs out. However, as Anderson (2003) points out, no-choice decision is not a homogenous concept, but may include procrastination, preference for status quo, or trade-off between effort to make a choice and expected benefits. One can also consciously wait for better options to emerge in the future. No-choice can be thus a deliberate – and rational – decision.

The decision to abstain from making a choice may involve staying at the status quo position (Samuelson and Zeckhauser 1988; Masatlioglu and Ok 2005), which stems either from a direct preference for the status quo or from being overwhelmed by choice options. This bias increases with the number of choice alternatives, which may be perceived as a rational response due to transition costs and uncertain outcomes. Samuelson and Zeckhauser (1998) argue, however, that it is rather psychological factors that discourage people from transition to better allocative positions and we should turn to loss aversion, endowment effect and psychological commitments in explaining this phenomenon.

The choice overload effect can, however, be moderated in certain circumstances and not all experiments were satisfactorily replicated when it came to report negative feelings. Scheibehenne et al. (2009) claim that the effect depends on multiple boundary conditions and interaction between several factors, so even if the choice overload effect exists it is not as robust as previously thought. The moderators of the effect can be grouped into three categories (Scheibehenne et al. 2010): assortment structure, decision strategies of individuals, and the perception of options' quality. For example specific arrangement and categorization of options, mindful decision strategies and choosers' heuristics can facilitate the process of choosing. Also Inbar et al. (2011) found evidence that regret from choosing even from a large set of option is eliminated if people have enough time to consider their choice. All this implies that there exist important preconditions for the choice overload effect to occur, but there is still no comprehensive study incorporating these factors into more general theory.

Other studies show that people actually experience the greatest satisfaction when choosing from intermediate set of choices, not too small and not too big. Reutskaja and Hogarth (2009) suggested that with increasing number of alternatives both costs and benefits rise. The difference is, however, that costs tend to escalate, whereas benefits satiate. The discrepancy between them rises leaving people less satisfied. Also, the change in perceived costs and benefits will affect the satisfaction function – the framing

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

of options and decision does matter. Similar results were obtained by Reed et al. (2011) who linked the dissatisfaction from extensive choice with effort needed to evaluate options.

Welcoming choice into pension policy schemes

For the last three decades policies of welfare state and social security have undergone extensive transformations in many advanced countries. According to the retrenchment slogan, the state was supposed to gradually back off from providing social benefits, because the market-based alternative promised delivery of the same services, only in a cheaper and more effective manner with greater respect to citizens' preferences². The state was thus supposed to guarantee that everybody, who was eligible, would be provided with social benefits or social assistance, but there was apparently no reason for the state to be the only supplier of such goods and services. It was widely believed that the previous system with public monopolies and uniformed service was inefficient, expensive and of poor quality. In effect, it was not matching the expectations of beneficiaries and offered very limited rewards for professionals employed in welfare services. Introduction of new policies was also expected to lessen the burden for public finances, reduce unnecessary administration and bureaucracy, and eliminate inefficiencies that tend to appear in the public sector.

The policy shift entailed a turn toward more individual approach to recipients; it encouraged private initiative and above all allowed for more personalized choice. However, introducing more choice into welfare policy raised a number of important issues. In principle, the expansion of choice should increase opportunities and enhance equity if we still assume that public policy should increase welfare of citizens (Le Grand 2007, Greve 2009). From this standpoint more choice can actually be largely useless if it is not possible to use it or only some recipients are able to take advantage of it. Traditional policies of welfare state utilized standardized measures for a reason. They were expected to eliminate market failures by exercising public intervention where there was no well-functioning market and by doing so reduce inequalities for the sake of public good. However, current trends of reintroducing choice can restore previous concerns if done without thoughtful reflection on how to deal with market failures that can aggravate social divisions in the long-term. One can name several conditions

² See Winston et al. (2002) or Pierson (2006, ch. 6) for a brief survey of arguments in favor of retrenchment.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

that should be fulfilled to minimize this risk, like wide information access, low transaction costs, right incentive structure, sound design of competition, and social trust (Greve 2003, 2009), but virtually none of them can be accomplished by mere market forces. They all require the state to take responsibility for institutional design and continuous monitoring of relevant developments in the new public-private sphere of economic activity. Yet even then there is no guarantee that these market failures will be eradicated successfully.

The changes in welfare policies took place in many areas: health care, elderly care and primary to tertiary public education (see Blomqvist 2004 for developments in Sweden). However, one of the most far-reaching privatization reforms occurred within pension systems bringing up issues of institutional design and on-going governance (see Ebbinghaus 2011). Many countries adopted notional defined contribution scheme complemented with fully or partially funded individual accounts administered by private companies. As a result large streams of publicly collected funds were directed into private sector for long-term management. Reasons for reforms were numerous and its advantages highly praised. The former usually included society aging (increasing life expectancy combined with declining fertility), fiscal issues (budget deficits and rising public debt), transformations of labor markets (declining employment rates, growth of non-standard employment contracts and low-paid jobs, persistent unemployment), falling productivity of postindustrial economies, and finally changes in social life (earlier retirement, one-child family, raise of individualistic philosophy of life). New rules were expected to address at least some of these issues thanks to their impact on public finances, financial markets and microeconomic incentives³. For example the adoption of defined contribution principle assumed that annuities could be adjusted to the existing demographic and economic conditions so that public finances would be more sustainable facing adverse shocks. The new system would also contribute to higher economic growth through increased savings and development of capital markets.

Expected benefits concerned not only the macro level, but individuals were supposed to be better-off as well. With respect to funded accounts pension savers were granted choice that they did not have in the PAYG system. Now they could decide on their own on the allocation of a part of their savings and were granted influence on portfolio structure both in

³ Many of those beliefs seem, however, mistaken or exaggerated. See Barr and Diamond (2010, 2009) and Barr (2002) for more detailed elaboration and critical discussion.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

terms of bonds/stocks ratio and dispersion of risk granted by access to foreign markets. Individuals would also have stronger incentives for continuous participation in the labor market and for investments in skills and education, because the relation between contributions and benefits would be now more direct. Old-age consumption smoothing became thus more personalized and a matter of own foresight weakening its link with societal developments and inter-generational redistribution.

The expansion of choice had its limits though. Despite the fact that the system of individual capital accounts glorified personal responsibility and initiative, it remained mandatory in virtually all cases of reforming national pension systems. Pension savers were not allowed to opt-out in order to adopt their own saving schemes or to refrain from saving at all thus taking full responsibility for their future. Leaving reasons for this coercive aspect aside, it should be emphasized that this solution implied that the state took the responsibility for designing the institutional framework of saving schemes and still bears, at least partially, responsibility for functioning and social results of the new system. The main underlying reason is that a market for pension funds is not a straightforward, competitive market like one for simple consumption goods. This is a market established and designed by government presumably with the intention to construct healthy micro-economic incentives for competition between funds, which should depend rather on price and quality of products than on exercise of market power or successful marketing measures, so that certain socially desired goals can be achieved like old-age consumption smoothing or relatively secure pension saving. Yet even with successful design, markets for pension funds have features of their own which differentiate them from other, more simple markets of choice and competition. For instance, as we could see in the previous paragraph, the participation on this market is mandatory for all the wage-earners and individual entrepreneurs and as such they cannot abstain from pension saving within this particular framework. Demand for the product is guaranteed by the government, which makes it easier for the suppliers to sell, yet at the same time may induce reluctance or ignorance of buyers toward evaluation of offered options, even if their future incomes depend on it. These specific features of pension fund markets call then both for cautious design and continuous monitoring of developments.

The situation of individuals coerced to participate in the pension funds market is extraordinary as well. Most of all, an extensive choice invariably implies a trade-off: more choice equals more costs in terms of choosers' time, psychics and risk borne (Loewenstein 1999). Even a partial shift from

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

PAYG system to individual capital accounts involves increased dependency on financial markets, which display inherent uncertainty. This means that there is no safe investment strategy and even seemingly similar strategies may bring mixed results depending on stock/bond portfolio or developments of particular markets. In effect savers with the same history of contributions may receive very differentiated pension benefits. An obligatory system relying on choice imposes its adverse effects even on individuals that consciously abstain from making decisions: such savers are unintentionally drawn into comparisons and may experience feelings of anxiety caused by the fact that even no-choice implies an actual choice.

Moreover, when it comes to finances, people face a number of cognitive limitations as summarized by Barr and Diamond (2009), which add up to the limitations briefly described in the previous section. Individuals, for instance, tend to misunderstand uncertainties they face and options they are offered, they do not understand basic concepts of finance and complex systems of saving (like pension plans), they have difficulties with processing information of pension products even if they are provided with it (see also Lusardi and Mitchell 2011). In effect, the rising complexity of financial schemes and operations at the individual level has detrimental effects on personal involvement and results in disinterest, biased decisions and withdrawal from informed participation in saving programs. These psychological and cognitive factors of 'irrational' behavior are surprisingly common as reported by Fear (2008) in his study on Australia. Besides, it would be also very optimistic to assume that all citizens care about their pensions or that they do have preferences for saving schemes. Limited interest in pension saving may also be amplified by the fact that rewards of current foresight are usually located far in the future, which implies high uncertainty of the actual size of annuities and at the same time fuels procrastination and negative perception of future consumption capacity.

Empirical investigations on pension systems that allow for extensive choice have confirmed many of the above reservations. Most of the literature refers to the case of 401(k) pension system in the United States which features high degree of voluntariness, but the results are nevertheless meaningful. Iyengar et al. (2004) found that the increasing number of options offered to pension savers leads to falling participation in these programs. For every ten funds added to the choice set, the number of participants fell by 1,5-2%. In another study Iyengar and Kamenica (2010) observed that when faced with a large number of options, people not only refrain from participation, but also tend to choose simple, easy-to-understand options

even if these are more risky or inferior to other alternatives. Surprisingly, better options could have been chosen from a limited set of choice indicating that the search for simplicity impairs our abilities to process data. Beshears et al. (2006) and Madrian and Shea (2001) reported significant inertia of sticking to the default saving scheme in terms of contribution rate, fund allocation, and post-saving distribution. This bias for status quo accentuates the procrastination issue and emphasizes the need for sound default schemes in saving programs, which have substantial impact on long-term saving outcomes. The importance of the default option design has also been confirmed by the comparative study of pension systems from ten countries differentiated by economic development level and cultural and historical background (Tapia and Yermo 2007).

An overview of the Swedish pension reform

The new pension system was introduced in Sweden in 1999 as the previous defined-benefit system was found to be unsustainable in the long term for financial and demographical reasons. It also had structural flaws inter alia in being tied to the development of prices instead of the real economic growth or penalizing long working career and flat earnings profile over life time. The reform was expected to address these shortcomings and meet other goals, which can roughly be reduced to three basic premises that led the reform (Barr 2013):

- the need to introduce a clear link between contributions and benefits with respect to fairness across generations,
- financial sustainability of the system should be achieved by tying it to economic growth and demographic change,
- individuals should be granted more choice in investing part of their savings.

Essentially all these assumptions were met, at least in the pure design. The new rules for pensions have eliminated the regressive redistribution patterns of the old system. A brake mechanism was introduced in order to sustain the self-financing of the system, though at the cost of shifting the costs of adjustment on pensioners and pension savers. And finally introduction of fully funded premium pension system allowed individuals to make their own choice in funds' allocation, even though in relatively limited scope. This paper focuses on the third aspect of the reform that is on the institutional arrangements of the choice given to pension savers and on the adverse effects of extensive choice possibilities. Yet before we proceed

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

with the analysis, it is worthwhile to briefly sketch the concept of the whole reform so that the premium pensions can be viewed in a proper context⁴.

The previous pension system based on the pay-as-you-go principle provided a full pension after 30 years of contributions based on worker's 15 best years. Its introduction in 1960 was perceived as a capstone of socialdemocratic welfare policies. The need for reform was realized already in 1980s., but it was only in 1990s. that political circumstances were favorable enough to pursue necessary changes. The new system was designed in a cooperative manner by a parliamentary Pension Group consisting of the representatives of five parties representing ca. 85% of votes. The very essence of the reform was a change from defined-benefit principle into defined-contribution scheme. Final legislation was passed in 1998 and since 1999 the new system has been in power. It consists of three fundamental components:

- partially-funded notional defined contribution (NDC) pension scheme administered by the state (*inkomstpension*),
- fully-funded individual accounts in which a pension saver is allowed to choose up to five privately managed funds to administer his savings (*premiépension*),
- the guaranteed pension providing poverty relief for those with insufficient history of contributions (*garantipension*).

The system is complemented with occupational and voluntary pension schemes, which however lie beyond the scope of state's direct responsibility. One ought to realize though that occupational pensions provide significant incomes for many workers, especially those with the history of high earnings (even up to 25% of future pensions).

The basic logic of the reformed pension system is following. Every month 18,5% of worker's earnings is transferred into the pension system. 16% goes to the NDC scheme forming the basic income pension and 2,5% goes to individual accounts generating fully funded benefits. Both contributions are compulsory and collected by tax authorities. In order to receive full pension a contribution history of 40 years is required. The pension is calculated on the whole history of earnings and one cannot retire earlier than at 61 years of age. There is no fixed retirement age, but one is no longer protected by the Employment Protection Act after turning 67. A pensioner is also allowed to withdraw his funds from individual capital

⁴ For more detailed elaboration on the Swedish pension reform see Barr (2013), Palmer (2004), Palme (2005), Anderson (2006) or simply refer to the Pension Authority webpage www.pensionsmyndigheten.se.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

account flexibly both in terms of timing and percentage of funds (25%, 50%, 75% or 100%). This way capital left within funds still brings interests, but is exposed to market risk, whereas after withdrawal the funds are transferred into Pension Authority fund which provides a fixed interest of 2,2% per year, yet with minimal risk. The new system also contains several microeconomic incentives for the development of labor market as its performance was considered crucial for the future of the system. One thus gets credits for rearing children and having tertiary education, whereas staying outside the labor market (for instance due to unemployment or sickness) or working part-time results in lower pension. Persons with insufficient contributions history are guaranteed a basic pension or a supplement to the income pension, though one is eligible for full size basic pension only if one lived in Sweden for at least 40 years and has turned 65⁵.

Although the income pension has lost its fully redistributive character and the benefits are now more directly related to contributions, it is still based on a pay-as-you-go principle and cross-generational redistribution. However, the most progressive and far-reaching solutions concerned the premium pension system. This was largely a response to the critique of the previous system that was perceived as a vehicle for pensions' standardization and detrimental paternalism that deprived an individual of any influence on pension savings' management. Thus the center-right parties insisted on giving it more individual tint that would allow pension savers to make their own decisions and take more responsibility for their life as pensioners. It was also argued that individuals have the best knowledge of their own living and financial situation and thus are capable of making allocative decisions suited best to their preferences with respect to risk and potential profits. In effect the official aims of introducing the system were threefold (Socialdepartamentet 2013, p. 13-14):

- workers should be given opportunity to invest in the capital market in order to gain higher profits than an exclusively NDC system could provide. This way their future pension would not be limited only to the PAYG system which depends largely on GDP per capita growth,
- investments on the capital market would diversify the risk of receiving the pension solely from the PAYG system. This way pensions would be less dependent on the developments in Swedish economy and demography as well as in the sector of domestic economy one used to work in.

⁵ In 2015 the guaranteed pension was 7046 SEK per month for a married person and 7899 SEK per month for a single person (ca. 30% of average salary).

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

The risk of Swedish economy would be minimized mostly by promoting investments on foreign capital markets,

- the freedom of choice would offer pension savers individualized risk and profit schemes. By making individual decisions concerning investments one would adjust the expected profit to the bearable risk according to age, risk aversion, specific life situation etc.

As a result pension funds market was created that offered pension savers the possibility to manage a part of their savings in line with their own preferences of risk, level of management fees and potential profits. One was allowed to choose up to five funds at the same time for the allocation of premium pension's contributions. It was expected that a reasonable individual would now follow the developments on his savings account and react accordingly so as to maximize future benefits and reduce the risk. Who would perform it better than the pension saver himself? The adverse effects of pay-as-you-go system and state's inefficiency would now be at least in part eliminated especially that the design of the system was also supposed to reduce some of commonly known market failures.

**The choice architecture of Swedish premium pension system
and its results**

The pension funds market was worth almost 615 bln SEK in the end of 2013 and was still growing. It grouped 6,7 mln pension savers and pensioners and is eventually expected to grow to 7 mln participants. As a result of the new legislation, in the fall of 2000 70 financial companies offered 4,4 mln Swedes 465 funds to choose from. The number of funds was growing steadily until 2006, when it stabilized at just below 800. However, in January 2015 there was already 843 funds offered to pension savers administered by 102 companies. Most of the funds invested in stocks (566), much less in bonds (145), and some had mixed stock and bond portfolios (98). In addition there were 34 funds with generational design.

Such a large number of funds was expected to match best the differentiated preferences of cohorts joining the system every year, just as theory suggested. It was realized however that such an extensive choice set could produce significant transaction costs of information gathering and processing as well as a risk of being exposed to asymmetry of information and power between pension saver and fund managing companies. It was thus up to the 'choice architecture' whether these effects would actually appear or how strong they would be. A careful design of the premium pension system

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

could eliminate or at least mitigate some of the factors causing the choice overload phenomenon.

There are at least four features worth mentioning in this context. First and foremost, Pension Authority (*Pensionsmyndigheten*) was established to act like a clearinghouse and a middleman between pension savers and managing companies. It groups together all the requests to join particular funds, withdraw capital, change the investment fund etc. and executes them jointly. This means that it is Pension Authority that is allocating capital into pension funds, not individual pension savers. This has several important consequences (see Palmer 2004), but relevant to our study is that savers' legal and institutional position against the pension fund is significantly strengthened and thus countervails a potential asymmetry of power. Savers are also anonymous to managing companies and hence free of being subject to adverse selection practices or various marketing-related pressures. All pensions are also paid out by Pension Authority, not by private sector funds. Second, all relevant information concerning funds (portfolio structure, history of results, costs of management etc.) has been available since the beginning of the system at any time at the Pension Authority webpage contributing to the creation of extensive and reliable access to information, favoring high transparency and offering a possibility of making unproblematic comparisons between funds. This way an important step towards reducing transaction costs of information gathering and processing has been made. Third, a pension saver is allowed to change funds every day at no charge. One thus allowed to allocate one's pension capital freely with no fees or legal limitations put against him by managing companies. The factor of time is also made insignificant as one has as much time as one wishes to make a firm decision and execute it instantly. Thanks to the possibility of choosing up to five funds at once one does not have to commit to one fund only. And fourth, because the Pension Authority acts as a clearinghouse and pools all individual allocation decisions, it demands significant rebates from pension funds for managing pension capital compared to the fees charged on voluntary transactions. Pension system is thus cost-competitive toward traditional capital market and cannot differentiate between pension savers.

At the beginning effects were promising. In fall of 2000, when pension savers were first offered choice, 67% of individuals made one. Those that did not were transferred into state's administered fund AP7 S fa. However, 67% was the best result the system ever achieved (see table 1) as the percentage of newcomers that committed a deliberate choice began to fall

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

steeply and since 2007 holds at 1,6% level. In 2000 it was a breath of novelty: after a long political struggle for introducing choice into pension systems individuals were granted one and so many committed to making a deliberate choice. It was also a time of massive media campaign encouraging pension savers to choose for themselves and stressing that a proper choice will make a decent pension. Later the campaign faded away as much less persons was joining the system, usually at the beginning of their careers and so with very small capital to administer. The falling involvement in making a thoughtful choice contrasts with rising number of investment funds (figure 1). Between 2000 and 2006 the number of funds rose to almost 800, but this rather discouraged than stimulated potential choice makers. Recent rise to 850 funds probably did not help either.

Table 1. Percentage of newcomers making an active choice

Year	Total (%)	Women (%)	Men (%)	New savers (thousands)
2000	67,0	68,0	66,0	4420
2001	18,0	18,2	16,8	493
2002	14,0	14,0	14,3	196
2003	8,4	8,4	8,3	150
2004	9,4	9,3	9,5	129
2005	8,0	8,3	7,7	117

Another factor that may have contributed to the falling number of active choice makers was that the rate of return on capital was highly negative (see figure 2). 100 SEK put into the system in 2000 was worth on average less than 60 SEK two years later. Even though market recovered during following years, it plummeted again in 2008-2009 – the same 100 SEK was now worth below 80 SEK. This situation showed that individual choice in fact did not matter against overwhelming market forces, so why bother with time-consuming and stressful choice if the result was negative anyway? On

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

top of all, even if the rate of return was generally positive at the end of 2000-2013 period, it was still below the accumulated growth rate of the income pension based on PAYG principle. The notional defined contribution system generated thus higher returns for individuals than stock and bond markets during 13-years' period. In 2014 the situation finally reversed, but no one can guarantee that there will be no downturn again. This explicitly highlights the risk involved in retiring at the wrong moment when markets are contracting and accumulated savings are thawing.

Statistical data confirms that most pension savers are not interested in managing their accounts (see table 2). No more than 7% of savers made at least one change per year in their portfolios under 2000-2011 period. 51% of savers have never bothered to choose managing fund and were automatically transferred into AP7 Såfa fund. 20% of savers made an active choice once, but have been passive since that time, and 22% made less than one change per year. There is a possibility to deliberately choose AP7 Såfa or one of its subfunds (cautious, balanced or aggressive) which could explain the high participation rate in the state administered fund, but out of 3,1 mln participants only 142 thousands made intentionally such a decision until the end of 2013 (Pensionsmyndigheten 2014). 2,76 mln savers were transferred there because they have withdrawn from making any choice and 174 thousands due to inaction when their preferred fund was terminated.

Weaver (2004) reported results of polls which tried to find out rationale behind this kind of adverse behavior when the system took off. The most popular answers in 2004 were as follows. 28% of non-choosers claimed that they had no time or energy to make a choice; 18% were simply not interested in making any choice; 13% did not have sufficient knowledge to make an active choice; 14% believed that they still got much time until retiring and 10% felt that they had too little money to make any difference. Similar answers were noticed within the group that deliberately chose AP7 fund. 24% did not have the energy or want to choose; 24% wanted to be spared choice for now; 21% felt that they had too little information to make a choice; 17% had too little money; 13% felt that AP7 is safe and secure and only 6% thought that the results of the fund were good. A study by Palme and Sunden (2004) confirmed that the broad choice offered was rather pacifying, not stimulating, and that many individuals misunderstood or did not wish to take advantage of the features offered by the new system. Pension savers hardly diversified the risk; they tended to invest in home economy or even in a particular branch of economy, possibly the one they worked in. Many have also decided to make choice 'once and forever'.

Recent research have largely confirmed that Swedes do not feel comfortable in this particular field of decision making. Report by Social Insurance Inspectorate (Inspektionen 2013) showed that individuals in Sweden

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

have very limited knowledge on pensions and pension saving system even though they are provided with extensive information by authorities. It turns out that information campaigns performed by the Pension Authority have had very limited effect on increasing this knowledge in the long-run. This knowledge is, however, positively related with age, incomes, and education. Almenberg (2011) has reported on deficiencies in financial literacy in Sweden. Even if simple calculations gave satisfactory results, more complicated ones (like understanding compound interest) caused much more trouble. Many Swedes also have poor understanding of basic financial instruments. It is thus little wonder that a significant percentage of Swedes do not feel competent to make decisions that will determine their old-age economic security and so prefer to rely on the state or simply postpone the decision into future. Not everybody wishes to be a financial expert anyway – one could also doubt if it would be socially profitable. Was it not a principle of specialization and a division of labor that spurred economic success of the West?

The Swedish case described above indicates two important points so far. First is that the Swedish premium pension system *is* burdened with choice overload paradox even though many measures have been taken to at least partly mitigate this effect. *Homo economicus* turned out to be human again, with all the consequences involved. His cognitive abilities proved to be very limited and he acted according to his temporary feelings and changing preferences as well as biases towards status quo or procrastination.

The second point is that having a decent default option is of key importance when so many individuals abstain from making a deliberate choice. There is of course possibility to randomly distribute those pension savers among the existing funds forcing them to join private-sector administration (that kind of policy works for example in Poland), but it seems rather unjust and unethical. Pension funds have various rates of return and therefore two persons with equal contributions' history could end up with different pension benefits although *none* had made any active choice. Understandably, this caveat does not apply to voluntary participation in premium pension. Very similar case has actually been touched upon by recent government report indicating that the premium pension system will probably produce higher pension inequalities than expected (Socialdepartamentet 2013). An extreme example shows that for a very small number of individuals there is a difference of 25 percentage points in the average rate of return since the introduction of the system: 0,01% of pension savers got annual rate of -8% and 0,02% of +17%. If this trend continues, the first group

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

is expected to receive 1000 SEK of premium pension per month and the second group up to 200 000 SEK per month when retired. However, 95% of pension savers had the rate of return within -1% and +6% brackets. But even here the difference can be substantial: 3000 versus 10 000 SEK per month. Apart from rising inequality this situation also increases the risk of old-age poverty for a number of pension savers and can even be amplified by an unfortunate moment of retiring when markets contract.

The Swedish default pension fund AP7 S fa seems to be a very reasonable alternative to staying at private sector pension funds. It produced an average yield of 6,2% for 1995-2013 period, whereas an average pension fund only 4,8%. In 2013 the difference was exceptionally huge: 26,6% in AP7 compared to 16,7% in privately managed funds (Pensionsmyndigheten 2014). Such a favorable outcome for the state-administered fund can be attributed to the fact that as much as 90% of its assets consists of stock holdings (of which only 10% of Swedish shares), whereas in private funds less than 80%. AP7 S fa is therefore more profitable, yet burdened with higher risk at the same time. An important feature is that in 2013 the public fund enjoyed management cost of 0,12% of accumulated capital every year compared to an average of 0,39% in privately managed funds. The costs of state's management are thus much lower than in private sector even after the negotiated rebates. One has to remember though that even the state administered fund is vulnerable to markets' instability and it produced negative results in the same years as private pension funds did. It confirms, however, that the state is able to provide a decent substitute to private sector even within the exiting paradigm of fully funded individual capital accounts. Such common default fund is also a more ethical solution which can minimize pension inequalities and the risk of old-age poverty if carefully designed.

It is worth mentioning before concluding that the shortcomings of the existing choice architecture have not gone unnoticed and Swedish government is preparing a reform. The recent report (Socialdepartamentet 2013) indicated that there is a serious threat of arriving at socially unacceptable inequalities of pensions coming from the premium system and that too many individuals feel overwhelmed with choice options. The report points to the very limited knowledge on pensions among pension savers and an extensive number of funds as underlying causes of these developments. It also sketches two possible scenarios for the government to follow. First assumes staying within the same paradigm of choice leaving the huge number of options available. It will, however, overtly promote the default solu-

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

tion for those that not wish to make a choice as well as impose cost and risk limits on private funds so as to lessen the issue of future annuities' inequality. The second scenario breaks off with the extensive choice and assumes introduction of a limited number of funds (possibly ten). The default alternative will stay in power. These proposals are currently under detailed investigation by the parliamentary Pension Group and a final report is expected to be presented in September 2015 (Finansdepartamentet 2014). Interestingly, the report openly admits that scenario analyses are essentially questions of values that constitute government's priorities and expectations of specific results. Efficiency of institutional solutions are here of secondary meaning as it is largely easy to estimate costs and benefits of the changes. Here it is rather a trade-off between broad old-age security and current freedom of choice. It is government's task and responsibility to decide which one to choose.

Concludions

The case of Swedish premium pension system confirms that an extensive choice leads to choice deferral and a preference for staying at status quo even in situation of paramount importance for one's future economic security. These findings are hardly new in the light of choice overload literature. However, the occurrence of choice overload in the field of public policy is a rather new phenomenon and implicates new issues to reflect on. A democratic public policy ought to ensure – at least in principle – that more choice should bring about more efficient delivery of welfare and should not foster increase of inequalities. And therefore even the privatized system of public policy should be under constant observation of democratic government and adjusted in line with the adopted values and principles of social life.

Government's responsibility invokes the question of choice architecture: who it was designed for and what principles it was based on. Both in theory and in praxis, as the Swedish case shows. The premium system has been designed with rationally perceived interest of a pension saver in mind. It does the utmost to equip him with plenty of relevant information, allows for frequent and costless change of funds, aims at far-reaching reduction of administrative costs and protects his identity. And in doing so it mitigates the acknowledged effects of market failure and choice overload. Alas, flaws in this careful construction appeared when pension savers turned out not to be perfectly rational agents and the measures that were supposed to

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

facilitate the choice decision process proved pretty useless. This brings a lesson that a design based on rational choice is not everything. Policymakers should rely more on findings in psychology than mainstream economic theory to design tools efficient enough to remedy market failures. As Madrian (2014) recently argued, it is very often not about the inefficiencies of market structure or wrong incentives that make certain solutions fail – it could well be about human nature. Effective public policy should take this into account, even if it could be politically incorrect.

The Swedish case illustrates one more unintended effect of a theoretically well-designed public policy. It could happen that the falling number of active choosers, if not countervailed, will end up in a situation that the premium pension system was introduced only to benefit a small number of pension savers at the expense of majority. For the sake of giving the former freedom of choice and flexibility of allocation, the security of savings for all population has dropped. In turn, this can result in erosion of social solidarity and increased risk of old-age poverty. Current attempts to reform the system prove that government wants to resolve this problem before it gets too far. The forthcoming public discussion will show, however, if those that benefit on the new system are already strong enough to kill the reforming efforts.

**General Equilibrium Theory – Walras Versus
Post-Walras Economists: “Finding
Equilibrium” – Losing Economics**

JEL Classification: *A1; B2; D5; E4*

Keywords: *Walras; post-Walras; General Equilibrium Theory; Modern Theory; Unrealistic Assumptions*

Abstract: This paper shows that the post-Walras general equilibrium theory is irrelevant to real contemporary economic life. The main achievement of modern General Equilibrium Theory is the proof of equilibrium's existence. It might be that the proof of the equilibrium existence is a mathematical achievement, but the question is whether these proofs are harmonious with the economic situation in reality. This paper traces concisely how Walras's theory has been became causing economic science to deviate in an erroneous direction and reaching a deep crisis; because post-Walras's economists, since Pareto, have misunderstood and misinterpreted Walras's economic theory. This group of Post-Walras authors (Pareto, Cassel, Schlesinger, Wald, and von-Neumann, Hicks, Keynes, Lange, and Patinkin) then recast Walras's theory into incorrect and wrong form; their error further compounded when a later group of economist-mathematicians (Arrow, Debreu, Friedman, Samuelson, Solow and others) accepted their interpretation without reservation. Post-Walras's economists ignore Walras's less known assumptions and blame him for disregarding the problem of equilibrium existence, uniqueness and stability and comparative-static. Therefore, their main objective since the beginning of the 20th century was the rigorous proof of equilibrium existence. However, this proof was based on unrealistic assumptions and along the road *the goal of economics was*

18-19 June 2015, Economics and Finance**

lost. The nine crucial, unrealistic assumptions will be considered and will illustrate that modern general equilibrium theory is irrelevant to real economics and is also far removed from Walras's general equilibrium theory.

Introduction

One of the main causes of the current financial -economic crisis is a crisis of economic science, which has been occurring from the beginning of the last century, namely, after the Neoclassical Economic School (Walras, Marshall). Despite the fact that the real economic life over the past century has greatly improved, state of economic science is deteriorated. Almost all of the topics of economic theory or degraded, or are at the beginning of the last century. Nevertheless, it is very difficult to call a new paradigm-rich modern economic theory to replace it classical or neoclassical paradigm. This statement may seem very strange, considering the "revolution in economics" (Keynesian, monetarist and rational expectations) and the fact that every year there is new Nobel Prize in Economic Sciences. This statement seems even more strange in light of the emergence of useful tools such as mathematical (linear) programming and other areas of operations research (especially game theory), econometrics, and, of course, powerful and "smart" computers.

The debate on the methodology of economics between theorists, economists, philosophers and historians of economics economic thought suggests that there is still no consensus on the methodology of economics. One group of authors argues that the theory should be close to the economic reality as possible. At the same time, another group of authors suggests that unrealistic assumptions character determines the measure of the significance of the theory. We support the first approach.

There are the following three statements: first, to be an inverse relationship between theory and reality; Second, the abstract theory means simplification of the real economy by assumptions; and third, the main objective of such a theory should be its practical implementation. The last statement is closely related to the previous as if the abstract theory distorts reality its use is not possible. In other words, there must be an interconnection between abstract theory and reality. Moreover, the relationship between theory and reality should serve as a criterion whether there is progress (development) or regression (degradation) in economic science. Classics (Smith, Ricardo, Marx) and Walras, Marshall suggested that the theory should be as close as possible to the economic reality.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

The "abstract method" means that the theory reproduces the real economic life only in a simplified form, so that the theory should not contradict reality, and directed it. It is clear that the abstract theory can never reproduce reality exactly, but should be as close as possible to it (Marshall, p.1).

For example, Walras's theory is characterized by free competition, uniform prices, but does not address the public sector (taxation) and international trade. At the same time, in Walras's approach in equilibrium voluntary unemployment may exist with a positive price. In the post-Walras approach (including the present), this price is zero, which contradicts the reality (Arrow and Hahn; Debreu, 1959; Mas-Colell and et. Al). As a result, we are not "abstract method" and absurd situation.

The scientific method is also characterized by an evolutionary approach, which means compatibility between the progress of human society and economic theory; therefore, the paradigm should be changed in accordance with the development of the real economy in such a way as to ensure compatibility between them.

Thus, in order to establish whether there is either degradation or progress of economic science for a specific period of time, it is necessary to compare the mathematical model and assumptions of the beginning and end of the period that allows you to see whether there is a new paradigm.

Those who argue that there is a significant improvement in the general equilibrium theory (Negishi, 1989; Weintraub, 1985 and 2002) and those who are skeptical about the theory of general equilibrium (Rosenberg, 1983) are wrong. Namely, they have misinterpreted and misunderstood Walrasian general equilibrium theory (Davar, 1994, 2012 and 2014b). Recent publications in the economic literature regarding the Walrasian general equilibrium theory (Bridel, 1997; Van Daal and Jolink, 1993; Walker, 1996 and 2006) do not shed light on the true interpretation of the Walrasian approach. As a result, all statements about the progress or regression of economic theory are questionable.

The paper consists of this introduction, three sections and a conclusion. The second section, Walras's method of general equilibrium theory is briefly is discussed. The third section, concise story how Walras's theory became irrelevant to reality is considered. The fourth section deals with unrealistic assumptions of modern general equilibrium theory. Finally, conclusion is presented.

Walras's Method of General Equilibrium Theory

Let's discuss very briefly Walras's method of establishment and re-establishment of equilibrium. Walras used the common method of equilibrium establishment and re-establishment (variation of prices) in the four types of economies (Davar, 1994 and 2014b).

The first economy, the Exchange Economy, deals with the problems of the exchange of consumptions' goods, namely the problems encountered when determining the equilibrium prices of consumable goods. Walras formulated a law to establish equilibrium prices for the exchange economy.

The second, Production Economy, is an enlarged version of the exchange economy. Namely, productive services (labor, fixed capital and land) are combined to produce consumers' goods. Therefore the problem of establishing the equilibrium price of services is discussed together with the price of goods for consumption. Furthermore the conditions of the law of equilibrium for the production economy, combines the law of the exchange economy (equilibrium prices of consumption's goods) with the law whereby the services' equilibrium prices are established.

Walras formulated the third type of economy, Capital Formation and Credit, by enlarging the production economy by adding the production of new capital goods (investment) and saving. This means that at this step in his theory the problems of new capital goods production and their subsequent demand in parallel with the problems of creating saving are additional issues of capital formation. The general law of equilibrium of capital formation formulated by the law of capital formation and combined with the law of production.

The fourth type of economy, Circulation and Money, is enlarged by the problems of Capital formation and credit. Here Walras added the problems of the determination of prices and quantities for raw materials, circulation capital goods and money for circulation. For this purpose Walras considered problems of determination of the demand for money for circulation for both consumption and production, and of supply of money for the production. So, the law of circulation and money is obtained by combining the law of capital formation and credit with the law of circulation and money. *Therefore, this law includes the laws of all types of economies.*

It could be said that the term "money" makes an illusion that in Walras's previous economies money is absent. However this is incorrect, because a *numéraire* fulfills all the three main functions of money (standard of measure, tool of exchange, and store of value), which might be ex-

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

pressed by means of any good (from goods for consumption), and is attributed to all the various types of economies of Walras (Walras, 1954, p.189). Therefore, in the fourth type of economy (circulation and money) together with the *numéraire* Walras used fiat money, as a specific character of the last economy and employing it as money for circulation. So, in the last type of economy Walras considered two kind of money: money commodity (*numéraire*) and fiat money.

Walras first considered the problem of establishing equilibrium for given basic data for the economy of individual (utility functions for each commodity and services separately, and available quantities of goods and services). Determination of the supply and demand for goods and services for each individual economy is the first step for the random price system. Yet, either the offer of or demand for a commodity used as the *numéraire* depends on the balance between the total value of demand (expenditure) and the total value of offer (income) of the commodities not used as the *numéraire*. The total supply and demand of goods and services may be calculated from the results of models of individuals' economies.

At this stage, for the entire economy, Walras formulated two models (equation system) for the equilibrium state and the disequilibrium state, and described the process of establishment of equilibrium by means of the *tâtonnement* algorithm (Davar, 1994, 2002, 2005, 2014b; Negishi, 1985, pp.170-3; Van Daal and Jolink). Namely, Walras shows how this iterative process transforms any initial disequilibrium situation to the equilibrium situation if it is possible, and by this, guarantee its solvability. The each isolated iteration of *tâtonnement* is divided into two stages: firstly, equilibrium establishment for a certain good (or service) – *partial equilibrium*; and secondly, general equilibrium establishment for all categories simultaneously – *general equilibrium*. Walras asserted that the partial equilibrium of a certain category would be exist if the essential assumptions plus the additional requirement, that is, the total (aggregate) demand curve and the total offer curve have *at least one intersections point* (Walras, 1954, pp.108 and 171). It must be stressed that there are economists who has been claiming that Walras's *tâtonnement* is the process of adjustment only of prices without of quantities (Leijonhufvud, p. 99). Yet, in Walras's approach, *there might be voluntary unemployment; moreover, according to Walras's approach also might be considered "forced unemployment"*.

Walras concentrated throughout on the *Law of Equilibrium State*, which is different from the well-known "Walras' law" formulated by his followers (Morishima; Davar, 1994 and 2012). While the Law for more advanced

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

economies only applies to new markets entering the system, it automatically includes the law relating to earlier types of the economy. For example, the Law of Capital Formation and Credit only relates to new capital goods, saving, investment and rate of income. Thus the equilibrium law for consumer goods and services for earlier types of economy (exchange and production economies) is integrated into the law for the economy in question (capital formation and credit).

Moreover, Walras discussed the variation of prices, or re-establishing the equilibrium following changes in the given basic data for an individual or group. This means that if any individual discovers that in the equilibrium state his services (or goods) are not traded, he might change his basic data according to the results of the obtained equilibrium state (Ingrao and Israel). Then, the new process of equilibrium establishment is required.

When Walras's approach is discussed in the post-Walrasian literature, unfortunately, the both models of individual's (micro) and entire (macro) economy is presented either through the exchange economy (in general), or through the production economy¹. Moreover, this representation of Walras's model differs from his original model and is incomplete.

Finally, Walras, as well as Marx, stated repeatedly that in reality equilibrium never achieved. At the same time, Walras asserted that study of equilibrium achievement it is necessary to managing real economics, by revealing the nature of distortion of equilibrium state and treatment them. Walras stated that:

Such is continues market, which is perpetually tending towards equilibrium without ever actually attaining it, because the market has no other way of approaching equilibrium except by groping , and before the goal is reached, it has to renew its efforts and start over again , all the basic data of the problem, e.g. the initial quantities possessed, the utilities of goods and services, the technical coefficients, the excess of income over consumption, the working capital requirements, etc., having changed in the meantime. Viewed in this way, the market is like agitated by the wind, where the water is incessantly seeking its level without ever reaching it (Walras, 1954, p.380).

¹ 'What 'cutes' "know" about Walras amounts to the following caricature. Walras developed the general economic equilibrium model, but did not care about uniqueness and stability of an equilibrium' (Backhaus and Maks).

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

And

The state of equilibrium, to which real markets always tend without ever attaining it, would be situation in which both supply of and demand for each service or product, and the cost of and selling price of each product, were equal (Walras, 2005, p. 365).

Walras asserted that applied theory deals with a situation when conditions of equilibrium are permanently destroyed. In the world of Pure Theory, where the regime of free competition prevails, such distortions will automatically be transformed to new equilibrium. But in the real world there are other market types (monopoly, oligopoly, unions, and so on) as well as free competition, and therefore such a distortion would be persistent. In order to minimize the damage yielding from distortion of equilibrium, both Marx and Walras asserted that the State's intervention is required.

Concise story how Walras's theory became irrelevant to reality;

Selecting economic theories (authors) to be compared with basic (Walras's theory) is very difficult and responsible task because there are a lot of theories (authors) that deserving to be choose and hence there is a permanent risk of making a mistake and choosing the "wrong" author at the expense of the "right" one.

Pareto's General Equilibrium Theory

It is well known that Pareto is considered as Walras's partner in the foundation of the Lausanne School of General equilibrium theory (Ingrao & Israel; Menard; Weintraub, 1985). It is implied that in principle, Pareto's approach is generally similar with Walras's one and these authors sometimes replaced each other; i.e. until today Pareto's and Walras's approaches are even mixed. Pareto, however, who was Walras's direct successor, criticized Walras's theory and tried to create his own general equilibrium theory. Therefore, it is very important to understand the relationship between these theories: Are they identical (similar)? If they differ, then what theory is more relevant to real economic life? In my book (Davar, 1994) Pareto's approach was not discussed at all. Pareto was quoted only once to stress that in consequence of Walras, who assumed positiveness of prices, he also recommended positiveness of prices. So, I have proposed, as many other

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

economists have that such authors either did not read Pareto's original works or read but did not understand them, that Pareto's approach is not similar with Walras' one.

Pareto has four main claiming against Walras' general equilibrium *theory*. First, Pareto stated that in Walras' approach prices are constant, while he assumes that prices might be also variable (Pareto, ME, p. 80). This means that Pareto considered two types of variability of prices: first, price of product varies in the macro (whole) economics level, but for individuals price is a uniform. But, this is exactly the case of Walras's approach – prices of commodities are varied in according to change of quantities. Therefore, in order to establish equilibrium Walras used his famous algorithm *tâtonnement*, by means of which passing from one price system to another is occurred until either equilibrium stated, is established or it will be clear that equilibrium does not exist. Nevertheless, Pareto stressed repeatedly that Walras discussed only the case with constant prices (ME pages 61, 83, 94; M p. 448). And it is not accidental that Pareto, our best knowledge, no one reminded the term "*tâtonnement*". This statement, that Walras considered only constant prices, is one of the important flaws of Pareto's understanding and interpretation of Walras' theory. Second form of prices variation, Pareto assumes that prices might vary even for each individual, which is connected with Pareto's fourth claiming (vide infra). It is necessary to point out that Walras did not included prices discrimination in his general equilibrium system, but he discussed such possibility since this derived from the real economic activity. Hence, Pareto had considered theory where prices are variable and at the same time discussed "Walras' theory" with constant prices (Pareto, M, p.155).

Second claiming, Pareto believed that measurability of utility is unnecessary for the consumers' choice and of course for equilibrium establishment (Pareto, ME p.68). Therefore, instead Walras', cardinal utility Pareto used ordinal utility (*ophelimity*).

Third, Pareto criticized Walras' assumption – constancy of production coefficients (Pareto, ME, p.94 and M, 448). Hence, Pareto tried to consider both variable and constant coefficients of production.

Finally, fourth claiming, Pareto stated that Walras considered only economy with free competition. It is necessary to stress here also that Walras really confined himself in his general equilibrium theory by free competition. But, Walras stressed that real economic life is characterized by number of different types of market and discussed them (vide supra).

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

Hence Pareto tried to consider equilibrium theory together with free competition also economy with monopoly (Pareto, ME, p.81).

The central flaw of Pareto's approach is that the direct relationship between prices and quantities for both goods and services (The Law of Demand and Supply) is ignored, instead of that Pareto discussed about it repeatedly and widely. This conclusion derived from the fact that in Pareto's approach prices are unknowns that might be either constants or variables. This means that in Pareto's approach prices are obtained by the solution of the system of equations together with quantities. By this Pareto thought that he "realized" Walras approach that prices are determined by the process of equilibrium establishment. But, the point is that Walras in his approach assumed existence of the total direct demand functions (curves) for the goods and the total direct supply functions (curves) for services. The latter means that albeit prices describing equilibrium state are unknowns the framework where they might vary is given in advance. This is the reason why Walras used *tâtonnement* for the transition from one given system of prices to their other system obtained in according of the law demand and supply for the given framework.

There are eight significant differences between Walras's and Pareto's General Equilibrium Theories:

- According to Walras's approach the individual economy and the entire economy are separated for all four of economy: exchange, production, capital formation and money. Pareto combined them within one model and considered only the exchange and the production economies. Therefore, Walras's economy is a *decentralized economy*, while Pareto's economy is a *centralized*; yet, even if there is a theoretical solution to Pareto's model, it is impossible to realize practically, as Pareto frankly confessed;
- Walras has used cardinal measure of utility; while Pareto from the very beginning has used ordinal measure of *ophemility*, but later has passed to cardinal measure;
- Walras has used separable utility functions; whilst Pareto has used the utility function included all goods and services together in one function, which from the practical point of view is problematic, if not impossible;
- According to Walras's approach, the demand and supply of goods and services are obtained directly from the solution of models. The offer quantity of a certain good (service) must be less or equal to its available quantity. In the Pareto's approach the final endowment is directly determined for all commodities and their sum is equal to the sum of their

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

- initial endowment; which prevent discussing employment-unemployment problem in the macro level;
- Walras first formulated a macro model, a simultaneous equation system, for the equilibrium state. He then formulated the disequilibrium (working) model, where the number of unknowns is larger than the number of equations and described the process of equilibrium establishment by means of his well-known algorithm – *tâtonnement*, which transforms the initial disequilibrium model into a final equilibrium model. Pareto did not use *tâtonnement*;
 - According to Walras’s approach all prices are unknown for the macro model, but they are known for the micro model; yet, they are strictly positive. In Pareto’s model all prices are unknown and some of them might be equal zero;
 - Walras had a certain success in showing that general equilibrium exists. Pareto, however, ignored the issue of whether equilibrium exists, and reduced it to comparing the number of independent equations and unknowns;
 - Walras used two categories of money: (1) money (money commodity-*numéraire*) serves as the functions of money, and its price is one; (2) money (money commodity-*numéraire* or fiat money) is used for circulation, and its price is the rate of interest. Pareto ignored money issue.

Hicks’s Value and Capital

In the 30-40th previous century, parallel to the proving the equilibrium existence (Wald; Von Neumann) two works were published influence of which have been continuing until today. First work, *Value and Capital* of Hicks, have been serving as the source of stimulation of development of the economic theory after the Second World War. Hicks had a very significant influence on such eminent authors as Arrow, Samuelson, and Morishima by their own confession. It is convenient that Hicks is generally considered to be the “discoverer” of Walras’s General equilibrium theory for readers of English. From the very beginning Hicks held twofold opposing views on Walras’ theory. On the one hand Hicks rated Walras’s theory very highly and on the other hand he claimed that Walras’s theory might be incorrect. Hicks also noted erroneously that Walras’s books except *Pure Elements* were not interesting (Hicks, 1934). It is also necessary to stress that Hicks played a leading part with Keynes in the splintering of the General Equilibrium Theory into two separate theories – Microeconomics and Macroeconomics.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

nomics. Consequently, he played a crucial role in *directing economic science towards an erroneous direction*.

So, Hicks misinterpreted and misunderstood Walras's general equilibrium theory and in the following, the crucial differences between Walras's and Hicks's approaches are listed:

- According to Walras's approach the demand and the supply of each commodity is directly determined simultaneously together with the final endowment on the basis of a given initial endowment for each individual by the solution of a micro model. According to Hicks's approach however, only the final endowment is determined.
- There are *two macro models* for the adjustment between individuals according to Walras's approach: a) A model of an equilibrium state – simultaneous equation system; b) A model of disequilibrium state – where the number of unknowns is larger than the number of equations. Hicks considered *only one macro model*, namely the model of an equilibrium state.
- According to Walras's approach an equilibrium state is determined to exist when the total effective demand is equal to the total effective supply for every commodity. Additionally the equilibrium quantity ought to be either less or equal to the total available quantity. Hence, according to Walras's approach *there might be unsold goods in an Exchange Economy, with positive prices for the sold goods*. According to Hicks's approach however equilibrium state is determined when the final endowment is equal to the initial endowment for every commodity. Hence, here it seems as if *whole available quantities participate in the exchange (trade) process*.
- According to Walras's approach the equilibrium state is established by *tâtonnement* (iterative process), which *transforms the initial disequilibrium model into a final equilibrium model*. Hicks considered *only a solution of the equilibrium model*.
- *Prices, according to Walras's approach are positive*, not only in an equilibrium state but also at each stage of iteration and adjustment. This is because prices are determined and varied in the given framework of the total demand function of goods and the total supply function of services. According to Hicks's approach, however, *equilibrium prices may be either positive, equal to zero, or even negative*.
- According to Walras's approach the initial endowment (quantities and utility functions) is not changed during the whole process of equilibrium establishment. After that any individual or group of individuals may

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

change it. It is then *required that equilibrium has to be reestablished*. Hicks also considered the problem of stability but importantly *only for price and income adjustments*.

- According to Walras's approach the production economy in an equilibrium state might be characterized as a situation in which *there is a voluntary unemployment of services with a positive price for its employed segment*. However the production economy of Hicks uses only the categories of final and initial endowments and therefore, Hicks *did not discuss at all the problems of unemployment (voluntary-involuntary) in the equilibrium state, i.e., full employment is assumed*. The same is also true for the *IS-LM* model.
- In the capital formation and credit economy of Walras *the equilibrium magnitude of the rate of income* is obtained by a comparison between total saving (net income) and total investment (the total value of new capital goods). Hicks though, only discussed the problems of saving and investment in the text of *Value and Capital* without according them a model in the appendix. In the *IS-LM* model Hicks *assumed that saving always is equal to Investment, which is correct only for an equilibrium state*.
- Finally, according to Walras's approach, in a Circulation and Money economy *the equilibrium rate of interest of money is determined by a comparison between the total offer (given) of money and the total demand for it*. Hicks, however only mentioned the problems of money in the text of *Value and Capital* without including a model in the appendix of his book. Moreover in the *IS-LL* model, *an equilibrium magnitude of the rate of interest is established by the relation between the rate of interest and Income*, namely, between the curve (*LL*) and the curve (*IS*). *It is however worth stressing that is very uncertain whether these curves can be drawn*.

The results are: *first, GET has become irrelevant to real economic life; second, Microeconomics has not developed since Walras (Clower); and third, Macroeconomics has never achieved maturity*.

Lange's "Walras' law"

Second work, Lange's well-known paper "Say's Law: A Restatement and Criticism", where he firstly used the term "Walras' law" in economic literature which essentially differs from Walras's original law and which has been, unfortunately, playing crucial role in the modern GET in the

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

proof of the existence of equilibrium state. There is the system of laws, which Walras formulated and used throughout his theory for each type of economy, which are not mentioned anywhere - from Pareto until the modern authors. However, Pareto's optimum which is incomplete expression of Walras's law of Demand and Supply is the cornerstone of the modern economic theory. Lange, unfortunately, did not take into account the system of laws formulated by Walras himself and even he did not mention them.

"Walras' Law", which is one of the crucial foundations of modern economic theory as formulated by Lange, and modified by the modern authors, differs essentially from Walras's original laws. Moreover, it is an intermediate stage of Walras's own Laws, and there is a significant difference also between Lange's and modern authors' versions of "Walras' Law" (Davar, 2012).

First, Walras formulated two systems of law for the framework of the system of assumptions: (1) the law of equilibrium establishment for each type of economy for the initial given data, so that the law for the economy in question related only to the new markets that entered in this level of economy, and laws of the previous level of the economy are automatically included; (2) the law of variation of prices, or the law of the re-establishment of equilibrium, as a result of changes in the given date for any individual or any group of individuals for each type of economy. In contrast to this Lange formulated one "Walras' Law" which is common for all types of economy.

Second, in Walras's approach equilibrium is achieved for each commodity separately connected to equilibrium for other commodities when effective demand is equal to effective supply which is less or equal to available quantities. Therefore, in equilibrium state there might be unutilized quantity for some commodities. In Lange's approach, however where there is equilibrium the excess supply of commodities is compensated by the excess demand for the money commodity, which is in a state of disequilibrium from the perspective of Walras's approach.

Third, in Walras's approach equilibrium for the money commodity is derived from equilibrium for other commodities for the exchange economy, i.e., equilibrium for the money commodity is guaranteed when equilibrium is established for all other commodities separately. Lange however stated the opposite situation, i.e., equilibrium of the money commodity guarantees equilibrium for other commodities.

Finally, in Walras's approach, all prices must be strongly positive and their equilibrium magnitude obtained from the framework of the primary

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

demand curves (functions) for goods and the supply curves (functions) for services. Whereas according to Lange's approach, as well as the post-Walras economists' approach, the number of prices, but not all prices, might be equal to zero, and might even be negative, because they are only obtained by the technological conditions of the model (Jaffé).

In addition, the interpretation of "Walras' Law" by modern authors is formally identical to Lange's one, but there is a significant difference. In the modern general equilibrium theory's approach the excess demand (supply) function is determined as the difference between demand and new produced quantities together with available quantities, while in Walras's approach excess demand is determined as the difference between effective demand and effective supply.

Consequently, in a modern GET determination of excess demand (supply) functions, two possibilities arise: 1) If there is a situation when excess demand for a certain commodity is less than zero (i.e., it is negative) price must be zero accordingly. But this contradicts reality. 2) If all prices are strongly positive then all excess demand functions must be equal to zero, which also contradicts the real economics. While, in Lange's approach, if there is excess demand for a certain good there is excess supply for another good. Therefore, the modern authors' version of "Walras' Law" and its function in proving of the equilibrium existence differs with Lange's one (Arrow and Hahn; Morishima).

These two versions of "Walras Law" not only are disconnected from real economics, but also are incompatible even with a hypothetical economics; and differ from the Walras's own system of laws, which are compatible with 'a hypothetical regime of perfectly free competition'. Finally and perhaps most importantly, "*Walras' Law*" replaced Walras's original laws not only in the textbooks but essentially in professional literature and has caused them to become unknown and abandoned and therefore, caused huge damage to economic science. The thought of an "alternate" to Newton's laws coexisting with the original is ludicrous, yet in economics such anomalies are common place.

Leontief's Input-Output Analysis

Leontief, in his famous 1936 paper, founded this new branch of economic analysis, both empirical and theoretical, and introduced the word "Input-Output", without which it is difficult to imagine the economics literature of the 20th century. From 1936 until today there has been considerable

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

improvement in the process of compilation of empirical input-output data tables and in the use of input-output for economic analysis. He stated (as did the Classics (Smith; Marx) and Walras) that the main object of input-output is to describe economic reality as closely as possible. Leontief also claimed that this goal might be reached if there is a reciprocal connection between the theoretical conception of input-output and its empirical treatment. Walras formulated the first mathematical model of general equilibrium theory without an empirical background. On the other hand, Leontief compiled the first empirical input-output, which was a natural expression of real economic life. Walras's model was used as the basis for the theoretical scheme of input-output by Leontief.

Leontief's input-output analysis are characterized some essential attributes. First, consumption (final uses) is divided into several categories: private and public (government) consumption, investment, changes in the stocks and export, and value added is divided into the several items: wages, profits and other value added, taxes, subsidies and imports for production. Second, the data, in general, were in monetary terms, that mean prices and quantities were not separated. Before describing Leontief's theoretical input-output model it is necessary to stress that from the very beginning Leontief gave importance and significance to presenting prices and quantities separately; however, because of that the practical economic activity has been an occurring in money (value) terms he also considered quantity in monetary terms. Therefore, Leontief presented two different versions of input-output systems. First, in general, one where quantities (physical) and prices (absolute-money) are separated (Leontief 1960, 1965 & 1974), and second, according to empirical input-output, where quantities are monetary terms and prices are in relative terms (Leontief, 1960 (1941) & 1986).

Naturally, there are some differences between these two systems. Leontief enriched Walras's system in accordance with the changes in real economic life. From that moment forward, and during his long life, Leontief applied input-output to different economic topics: dynamic aspect of economic, the choice of technology, trade in the world economy, environmental pollution and so on. At the same time, Leontief's theoretical scheme differs from Walras's system and it does not completely describe reality.

First difference, Walras used, in production part, circulating capital goods from the previous time-period, and which price is equal to price of good multiply by the rate of interest. While, Leontief used the total output (or input) of goods, produced in time-period in question, and its price equal to price of good. This is very significant difference, because it influences

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

on the results of the solution of the input-output model in two directions: (1) in the direction of quantity of good; it is clear that the current economics is characterized by using capital goods from the previous time-period and also by using of goods produced in the time-period in question. So, neither Walras's approach not Leontief's approach is compatible to the today reality; (2) in the direction of prices; prices of goods obtained by the solution of Walras's model might be significantly less than prices obtained by the solution of Leontief's model.

Second difference, according to Walras's approach, in equilibrium state, there might be voluntary unemployment magnitude of primary factors in the framework of his system assumptions, despite of that it is convenient that Walras's theory is characterized by full employment. Changing Walras's assumptions according to Keynes's approach there might be involuntary unemployment either with or without voluntary unemployment in equilibrium state. While, Leontief's input-output model did not discuss problems of unemployment at all, especially in the beginning of it appear. However, if we take into account the fact that in the modern economics it is difficult to find one country that not enduring by hard unemployment, this difference is vary actually.

Third difference, despite of that Walras's general equilibrium theory is static, there is equation discussing the relationship between saving and investment (the new capital goods), by means of the rate of interest. While, despite of that Leontief considered "dynamic model" of input-output, the relationship between saving and investment does not discuss at all. In addition, the dynamic model of Leontief, similar with his static model, did not consider problem of unemployment. Therefore, Leontief's dynamic model is incomplete and in such form it is irrelevant to today economics.

Finally, fourth difference, Walras's succeed to integrate money theory in his general equilibrium theory. As it was mentioned above, according to Walras's approach there are two different types of money. The first type of money for accomplishing the functions of money, and its price is one. The second type of money is used as its service for circulation, and its price is the rate of interest. Therefore, there is equation which discussed the relationship between the supply of money for circulation and its demand (required) quantity by means of its price (the rate of interest). While, Leontief's input-output model did not consider any problem of money at all. However, abandoning of money theory in the input-output analysis is crucial and is one of the central reasons that input-output is not using for the remedy of the contemporary financial-economic crisis.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

The modern general equilibrium theory-Arrow-Debreu

The Arrow-Debreu general equilibrium model is characterized by the strong proof of equilibrium existence, stability analysis and the problem of unique of solution. All these, however, are based on the free goods rule (non-Classical), which together with other flaws make Arrow-Debreu theory doubtful from the point of reality². These claims stay correct even after tremendous attempt to “alive” the theory by introducing economic problems such as imperfect competition, international trade, taxes, and so on. We mean so-called Applicable (Computable) general equilibrium theory (Makarov, Levin, and Rubinov; Shoven and Whalley).

The Arrow-Debreu model is closer to Pareto’s version of GE than Walras. This follows from the fact that the problem of the establishment of equilibrium is solved in one stage. In other words, all consumers and all producers are concentrated in one model. However, if there is a strong theoretical solution to the Arrow-Debreu model, it is impossible to realize practically even for a small country, as Pareto frankly confessed. In addition, in the Arrow-Debreu case, the adjustment process between supply and demand is superfluous. Another difference is that prices are obtained by the model’s solution directly, and not determined by means of the *given framework* of demand function for goods and supply functions of services. Hence, prices might reach any magnitude, and some prices might be zero. Therefore, prices in the Arrow-Debreu model do not have any connection to current prices. A final difference is that the utility function for each household is described as a function of all goods and all services in one function simultaneously which is practically unrealizable. Also, problems of unemployment, saving, investment, interest rate and money, and other economic problems are not discussed in this model.

² Allais claimed the same but by another reason: ‘Any theory whatever, if it is not verified by empirical evidence, has no scientific value and should be rejected. This is true, for example, of the contemporary theories of general equilibrium which are based on the hypothesis of general convexity of the fields of production, a hypothesis that is disproved by all the empirical data and leads to absurd consequences (1992,p.26)’ and ‘For almost forty-five years contemporary economic literature has developed too often in a totally erroneous direction with the construction of completely artificial mathematical models detached from reality (ibid. p.27)’

Unrealistic Assumptions of Modern General Equilibrium Theory

The nine crucial unrealistic assumptions observed during the process of "development" of Walras's GET will be considered and will illustrate that not only is modern general equilibrium theory irrelevant to real economics, but that it is also far removed from Walras's general equilibrium theory:

(1) *Price of several goods and services might be equal to zero and even might be negative.*

Post-Walras authors misunderstood Walras's method of equilibrium establishment, namely, that Walras used two macro model (equilibrium and disequilibrium) and demonstrated how disequilibrium model is transformed into equilibrium model by iterative process (*tâtonnement*) if it exists and by this achieve the solution; blamed him as if he considered only equilibrium model, characterized by equations system with equality (Cassel, Schlesinger, Wald, Zeuthen, von Newman). Therefore, they substituted the effective supply of factors by their available quantities and the cost of production by the given selling prices of commodities in the Walras's equations of quantities of services and of prices of commodities, respectively. Then, the demand quantities for services by sectors of production and prices of services are became unknowns.

Yet, the proofing of equilibrium existence is based on two unrealistic assumptions: first, *free good conception (non-Classical)*.

This assumption says us that when there is an excess supply of a service (a product), i.e., an unused part of the service (the good) it is called "free good" (mockery to the Classical free goods conception) and its price equals zero. In other words, in equilibrium, if a certain service is not fully employed, then its price is zero. For example, if unemployment exists, then wages should be equal to zero (Davar, 2011, 2012 and 2014b). But in this case, such a theory contradicts reality (*vide infra*).

Free goods rule (conception) (non-classical) is based on the replacement of the cause (good is being in abundance without any expenditures – like the goods of Nature) by the effect (its price is equal to zero). According to this conception, together with other assumptions, the equilibrium price of some goods and services, specifically when these are in excess supply, is equal to zero. For example, in an equilibrium situation, with high unemployment, wages have to be equal to zero. However, such wages contradict the real facts of economics. Therefore, the modern general equilibrium

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

theory is inapplicable to the real world, and its main achievement of proving the equilibrium existence, once it is based on these assumptions, becomes completely not useful and meaningless.

It must be stressed that the same situation is observed to Keynes's investment multiplier. The Keynesian multiplier is based on the substitution of the cause (the national income) by the effect (investment). By Keynes's definition, the multiplier must mean that an increment of the investment in a certain time would yield an increasing income by the multiple it of multiplier, in the future. Yet, the rate of the multiplier depends on the marginal propensity to invest (or the marginal propensity to consume) and the lower (or higher) the latter, the higher the multiplier. Consequently, in order to increase income, it is better to consume than to save. So individuals were encouraged to spend on consumption and not save. Therefore, for the last twenty years, the average propensity to invest in the United States was decreased and reached 0.04, which means that the multiplier have to be equal to 25. *This is unreal (!)*; and this is one of crucial reasons of the contemporary financial-economic crisis (Davar, 2014a).

Second, "Walras' Law", formulated by post-Walras economists, is one of the crucial assumptions of the MGET and differs essentially from Walras's original laws (Davar, 2012). Moreover, it is an intermediate stage of Walras's own laws. The "Walras' Law", unfortunately, has replaced Walras's original laws, subsequently; the latter have become relatively unknown and abandoned. *The thought of an "alternate" to Newton's laws coexisting with the original is ludicrous, yet in economics such anomalies are common place.*

The results of the solution of such equations system by the tools of mathematics are that some prices of services might be zero and even negative (Dorfman, Samuelson, & Solow). Some economists accepted that prices might be zero but disagreed that the price might be negative. Therefore, in order to eliminate such possibilities the equality was replaced by inequality. Unfortunately, this replacement caused another difficulty, and it yields the following unrealistic assumption. Whilst, according to Walras's approach all prices are strictly positive (Ingrao and Israel; Ginsburgh, and Keyzer).

(2) *Measurement of prices*

In modern GET measurement of prices is unclear, because those prices are obtained by the model's solution directly, and not determined by means

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

of the *given framework* of demand function for goods and supply functions of services where prices are measured in *numéraire* (money commodity) as in Walras's Theory. Moreover, prices might reach any magnitude, and some prices might be zero. Therefore, prices in the Arrow-Debreu model do not have any connection to current prices. Moreover, it was recently suggested that shadow prices (Lagrange multipliers) have been using as a prices even for practical applications of input-output analysis (Thijs ten Raa, p.15). Such statements mean a regression of economic science at least on fifty years.

(3) *All economic agents (consumers and producers) are concentrated in one whole model.*

This type of model, when all economical agents are included (comprised) in one model, differs from Walras's model where each economic agent (consumers and producers) solves his economic problems individually (separately) depending only on his personal goals (maximum utility, or maximum profits, and so on) by micro model; afterward, the adjustment between these individual solutions occurs by the macro model. In other words the process is divided into two stages: individual activities and the adjustment between them, i.e., establishment of equilibrium. It must be stressing that this approach is based on real economics and therefore, there is a natural integration between microeconomics and macroeconomics. In the case when all agents included in one model, the solution of individuals' economic problems and their adjustment (equilibrium establishment) has simultaneously occurred. This approach has two problematic issues: firstly, since models of all individuals are solved together, it is natural that an interpersonal comparison of their goals (utilities) occurs; secondly, and most important, such model has huge dimensions, which makes impossible its practical realization (solution) even by means of the modern superpower computer.

(4) *Unemployment*

The modern general equilibrium theory do not able to discuss problems of employment-unemployment, because that the excess demand (supply) for goods and services is determined as a difference between the final endowment and the initial (available) endowment.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

Such determination of the excess demand (supply) has some negative consequences from the point of economics. First, the demand and supply are not directly determined; therefore there is illusion that as if the whole available quantity of commodities and services are traded. Consequently, second, it is not clear what part of commodities and services is actually traded and what part is not traded, that is, what part is unemployed (unsold). Finally, despite of that the excess demand is sometimes determined as a function of prices the original linkage between prices and quantities is destroyed.

While, in Walras's approach, *there might be voluntary unemployment; moreover, according to Walras's approach also might be considered "forced unemployment"*.

(5) *There is only one type of money – fiat money.*

In the modern general equilibrium theory money either disappeared or is considered in very simplified form and with unrealistic assumptions.

Classics, who considered money theory as essential to and inseparable from economic theory, have discussed their reciprocal influence. One of Walras's major and unique contributions is the integration of his money theory into his general equilibrium theory which enabled him to consider the real economic and financial sector as one integrated system (Schumpeter p.1082; Marget, 1931 and 1935).

Majority of economists since Pareto, unfortunately, misunderstood and misinterpreted Walras's general equilibrium theory, especially, theory of money, and have been claiming that Walras's theory is both incomplete and even wrong (Hicks, 1934; Clower), or that the problem of money is not discussed by him at all. Economists, who realized that Walras discussed the problem of money in his theory, are claiming that he failed in the integration of money in his general equilibrium theory. Therefore, they have been attempting to reconstruct and rewrite it. Moreover, from the very beginning, Walras's money theory is simply ignored.

Crucial attribute of Walras's money theory, which was completely misunderstood and was absolutely given up, yields serious confusion: is the fact that Walras as well as Smith considered two types of money: money as a medium of exchange, a measure of value and store of value where the money commodity (*numéraire*) has to be served and money for circulation where either the money commodity (*numéraire*) or fiat money might be served. Thus, there are two different prices for the money commodity: (a)

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

when money commodity is used as a measure of value its price equal to one; (b) when money commodity is used in circulation its price equal to the rate of interest.

In contrast, in the works of most post-Walras economists, the economic and financial sectors are separated, and their authors have been claiming that money commodity (*numéraire*) is not money (Hicks, 1967, p.3).

Therefore, is not accidental that post-Walras's money theory is generally considered one type of money - fiat money (Kiyotaki, and Wright; Magill and Quinzii). So, from the seventies, the majority of countries of the world used a fiat money as standard money; fiat money replaced the money commodity and had to fulfill all four functions of money. But this is opposite with the principal statement of classical money theory, that only money commodity have to serve as a measure of value, and fiat money has to be only used in circulation. Moreover, the quantity of fiat money must be regularized by the quantity of the money commodity (Davar, 2013, 2014b).

The replacement of the money commodity by the fiat money has yielded several undesirable phenomena, predecessors of the financial bubbles. First, because the fiat money has no objective value, economics is managed without valuating of goods and services. Second, because there is only one type of money, namely fiat money, there is only one price – the rate of interest and the price of the money commodity is absent. Therefore, this is another reason why fiat money cannot be served as a measure of value. Third, there are no obstacles and no limit to printing paper money (Davar, 2011, 2013 and 2014a).

Walras emphasized the specific role of money in distortion of general equilibrium because that changing of price of money impacts directly on prices of almost all products and services. Hence, changing price of money yields changing prices of products and the result is a disorder of equilibrium, i.e., economic crisis. In the case of deep crises Walras *recommended that the State should intervene and regulate the quantity of money* (Walras, 2005).

(6) *Saving and Investment*

Modern GET does not discuss the issue of saving and investment at all, while Walras discussed this issue in detail in his third economy, “Capital Formation and Credit”.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

(7) Cost of production

One of central conditions of equilibrium, equality between the selling prices of goods and its cost of production (supply price) in the Arrow-Debreu approach cannot be kept, because the cost of the production of goods is directly not determined; because of this it is important that not only the price of some goods might be equal to zero, but also the price of some services might be zero. While, according to Walras's approach this condition of equilibrium is established by iterative (*tâtonnement*) process between cost of production and selling prices of goods.

(8) Utility function

The utility function for each household is described as a function of all goods and all services in one function simultaneously, which is problematic if not impossible from the point of real economics. This is opposite to Walras's approach where utility function is described for each good separately.

(9) Circulation capital, products and money

The problems of circulation capital, products and money are not discussed by the modern GET; while, Walras realized the property of money, as a service, entirely in the last economy, Circulation and Money, where money is also used as a service of circulation. This means that in the calculation in the equation of the cost of production of the produced goods the price of a certain product used as a circulation capital is determined as a price of product in question multiple a price of money's service, the rate of interest.

The modern economic theory, based even if on one of above mentioned unrealistic assumptions, is incompatible with reality; hence its applicability is doubtful, though from the point of view of used mathematics it might be indeed remarkable achievement. In practice, several unrealistic assumptions are simultaneously used by the modern economic theory for the serious issues.

Therefore, we can conclude that the Arrow-Debreu general equilibrium model is irrelevant to real contemporary economic life.

Conclusions

In this paper was shown that the post-Walras general equilibrium theory (included Arrow-Debreu model) is irrelevant to real contemporary economic life. The main achievement of modern General Equilibrium Theory (GET) is the proof of equilibrium's existence 'The proof of general equilibrium is the crowning achievement of mathematical economics' (Rosenberg; Arrow, 1989). It might be that the proof of the equilibrium existence is a mathematical achievement, but the question is whether these proofs are harmonious with the economic situation in reality.

In this paper was concisely traced how Walras's theory has been became causing economic science to deviate in an erroneous direction and reaching a deep crisis; because post-Walras's economists, since Pareto, have misunderstood and misinterpreted Walras's economic theory. The group of Post-Walras authors (Pareto, Wald, and von-Neumann, Hicks, Lange, and Leontief) then recast Walras's theory into incorrect and wrong form; their error further compounded when a later group of economist-mathematicians (Arrow, Debreu, Dorfman, Samuelson, Solow and others) accepted their interpretation without reservation. In fact, each of them, when carefully examined, was trying to create his own general equilibrium theory -- which formally resembles Walras's approach -- but actually is no more than a distortion of Walras's theory.

Modern mathematical models of economics and financial sectors are generally separated and are very complicate but majority of them are weakly connected with reality especially modern general equilibrium theory (Debreu; Arrow and Starrett; Arrow & Hahn; McKenzie; Mas-Colell, Whinston and Green; Shoven and Whalley). Instead of gradually updating some of the Walrasian old-fashion assumptions by new ones that are compatible with contemporary economics modern general equilibrium theory has been rediscovering and using almost all of Walras's assumptions; moreover, new, unrealistic assumptions were introduced, making modern economic theory incompatible to reality. Post-Walras's economists ignore Walras's less known assumptions and blame him for disregarding the problem of equilibrium existence, uniqueness and stability and comparative-static. Therefore, their main objective since the beginning of the 20th century was the rigorous proof of equilibrium existence. However, this proof was based on unrealistic assumptions and along the road *the goal of economics was lost*.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

The nine crucial, unrealistic assumptions were considered and illustrated that not only is modern general equilibrium theory irrelevant to real economics, but that it is also far removed from Walras's general equilibrium theory.

Finally, tremendous intellects sources of several generations of economists with enormous financial outlay have been wasted for more than 100 years on the subject that is not useful and meaningless for practical recommendations.

**Fertility Rebound and Economic Growth. New
Evidence for 18 Countries Over the Period
1970-2011**

JEL Classification: *J11; O10; C23*

Keywords: *fertility rate; fertility rebound; economic growth; panel data analysis*

Abstract: Long-run impact of economic growth on fertility trends is ambiguous and sensitive for in-time variations. Noticeably, over last decades, economic growth has led in many countries to significant falls in total fertility rates. However, recently, in high-income economies a kind of ‘fertility rebound’ emerged (Goldstein, 2009; Luci and Thevenon, 2011; Day, 2012), which supports the hypothesis that reversal trends in total fertility rates are mainly attributed to economic growth.

The paper unveils the relationship between total fertility rate changes and economic growth in 18 selected countries with fertility rebound observed, over the period 1970-2011, and detects the GDP-threshold at which the fertility rebound emerged. To report on the relationship we deploy longitudinal data analysis assuming non-linearity between examined variables. Data applied are exclusive derived from World Development Indicators 2013. Our main findings support the hypothesis on U-shaped relationship between total fertility rate and economic growth in analyzed countries in 1970-2011. Along with the previous we project the minimum level of GDP per capita (GDP-threshold) when the fertility rebound takes place.

Introduction

In 1994, Hirschman (1994) concluded that the picture arising from empirical evidence on changing fertility (measured, by convention, as period total fertility rate – TFR) is ambiguous and does not provide clear justification about its determinants. After twenty years of further studies, our knowledge about factors influencing fertility is much broader however; we still lack hegemonic theory on that field. Contemporary societies are highly heterogeneous, and the relationship between changing fertility rates and economic development is affected by multitude of quantifiable and unquantifiable factors; still, the negative relationship between fertility and socio-economic development is recognized as one of the best-established and consolidated regularities in social sciences. The cited regularity was empirically confirmed in prominent works of, *inter alia*, Becker (1960), Heer (1966), Easterline (1975), Van de Kaa (1987), Witte and Wagner (1995), Becker et al. (1999), Lee (2003), Myrskylä et al. (2009), Luci and Thévenon (2011) or Bacci (2013). The economic reasoning behind the negative relationship between fertility and economic development is following. As mortality and fertility rates decline¹, it allows for reductions in amounts of energy and resources necessary for childbearing (Kalemli-Ozcan et al., 2000; Orsal and Goldstein, 2011; Livi-Bacci, 2012 and 2013), resulting in higher women's engagement in market activities instead, potentially generating shifts in productivity. Weil (2013) also claims that as countries get richer, there reveal two specific effects, namely 'income effect' and 'substitution effect', which allow explaining why people tend to have less children as their income grows. Economically speaking, people value children as 'normal goods' on which they need to spend money. As people earn more, they – theoretically – can afford more children, but the previous is usually not true, as the relative *price* of rising children also rises. Childbearing requires time, which expresses the opportunity cost of not earning money from regular work; hence, the 'substitution effect' emerges, hence if the 'substitution effect' is stronger than the 'income effect' then the country's fertility falls. Weil (2013) additionally explains that lowering fertility may be determined by emerging 'quality-quantity trade-off' effect. In high-developed countries, children need to get good education, which is costly. Thus, people decide to have fewer, but better educated children, hoping for payoffs in the future and children's support in as parents get older in age.

¹ Note that in demographic perspective, the lowering fertility rates are a consequence of both declined in mortality and increases of life expectancy.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

Alternatively, they decide to have more children, but at the cost of their worse education. Whether people decide one or another, depends predominantly how they value children, what are the well-established social norms and attitudes, and individual preferences. But, as it is claimed by some scholars, see i.e. Galor and Weil (1996, 1999), Kohler et al. (2002a, 2002b), Deopke (2004), Caldwell and Schindlmayr (2003), Butler (2004), Morgan and Taylor (2006), Klasen and Lamanna (2009), Mills et al. (2011), the total fertility rate and economic development are rather linked by two-way, than one-way, relationship. The reverse causality between TFR and economic development is possible, but also heavily preconditioned by broad array of economic and demographic factors. However, most recent estimates provide solid background to claim a reversal of the previous negative associations between TFR and economic growth and development (i.e. Gubhaju and Moriki-Durand, 2003; Bongaarts and Sobotka, 2012). To support the previous, it is worth underlying that in Europe, the period 1998-2008 was marked by significant changes on the ground of total fertility rates (Bongaarts and Sobotka, 2012; Sobotka, 2012). In many European countries, TFR began to grow, after having fallen until unprecedentedly low levels in early 2000s (in 19 European countries, the TFR fell below 2.0). The evidence on a trial of escaping the 'low fertility trap'² in European countries, is reported in works of, *inter alia*, Prioux (2007), Goldstein et al. (2009) or Bongaarts and Sobotka (2012). Over the period 2000-2011, similar reverse trends in total fertility rate are observable in more than 60 high-developed and economically backward countries (to compare see World Development Indicators 2013). Surprisingly, Myrskylä et al. (2009), Day (2012, 2013) and Varvarigos (2013) find that the well-

² The concept of 'low fertility' is to a point ambiguous. As Bacci (2013) argues, in its simplest form, the low fertility occurs when it falls below 1. In such sense, the fertility rate is totally conditioned by level of mortality ('one for one'). However, in modern societies, where the life expectancy is high and mortality in reproductive years is close to zero, the replacement of populations is strictly depended on total fertility. Societies, where the total fertility rates oscillate around two children per women in her reproductive life cycle are labeled as low fertility societies (Bacci, 2012 and 2013). If the total fertility declines until around 1 or less child per women thus is named as 'ultra-low fertility' or 'lowest-low fertility'. The low fertility can be also subjectively perceived. To a point, fertility rates rely on individual expectations or preferences, social norms or ideals, religious attitudes, or finally state strategic targets. In such case, rigid notion of low fertility remains fuzzy and undefined. In general, from purely demographic perspective the concept of low fertility relates exclusively to population replacement, while incorporating the low fertility notion into social or economic ground, allows its perception in context of meeting broadly agreed social, economic or political targets (like i.e. in China 'one child' policy).

established negative relationship between fertility rate and economic growth turns to be rather positive, especially, at higher stages of economic development. Hence, the emergence on new regularities between TFR and economic growth is witnessed. The hypothesis on potential positive relationship between fertility trends and economic development – labelled as ‘U-shaped fertility dynamics’ (Day, 2013; Luci-Greulich and Thévenon, 2013), is supported by evidence on growing total fertility rates mainly in high-income economies (Myrskylä et al., 2011; Myrskylä et al., 2013). The changing trends in fertility rates are recognized as *fertility rebound*, defined as reversal of fertility decline accompanied by economic development.

The aim of the paper is to provide new evidence on relationship between fertility and economic development and estimate the GDP-threshold at which the fertility rebound emerged in analyzed countries. To meet the main targets of the paper, we re-examine the hypothesis on a U-shaped relationship, for 18 high-income countries over the period 1970-201, between total fertility rate (TFR) and GDP per capita. Our study consists of six parts, whereby the introductory part is followed by section two explaining theoretical background and literature review. Section 3 presents data rationale, whereas section four sets the main goals of the paper and adopted empirical strategy. The subsequent section five illustrates empirical analysis results and the final part refers to substantial conclusions in this respect.

Conceptual background

Recent empirical studies (see i.e. works of Goldstein et al., 2009; Bongaarts and Sobotka, 2012; Luci-Greulich and Thevenon, 2013; Day, 2013) provide well-documented evidence on the relationship between TFR and GDP per capita or – alternatively – socio-economic development approximated by Human Development Index. Although the evidence is relatively broad, the main conclusions they allow for, vary significantly showing complexity of the problem and multitude of factors, which potentially affect the two-way relationship between fertility and economic growth and development. Both in theoretical and empirical works where main emphasis is put on aspects combining fertility trends and economic development³,

³ Along with growing literature on the relationships between total fertility rates and economic development, there is broad empirical evidence providing demographic explanations to reversal fertility trends. Such evidence can be traced in works of, *inter alia*, Bongaarts and Sobotka (2012), Bongaarts and Feeney (1998), Bongaarts (2002), Sobotka (2004), Gold-

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

three seminal research streams are easily distinguishable, since each one offer different perspectives for the analysis. The first stream combines issues of changing fertility with economic development, the second – changing fertility trends with economic growth exclusively, while the third one confronts changing fertility trends with business cycles. The first and second one perspective are mostly long-term in nature, while the third one combined short-, and long-run approach. Myrskylä et al. (2009), in their prominent work, apply panel data for 37 high developed countries over the period 1975 to 2005, to examine the relation between the Human Development Index (HDI) and the total fertility rates. They suggest that HDI-TFR relationship tends to reverse from negative to positive, as countries pass *critical* level of HDI. Their findings show that, at low and medium level of human development index (HDI), decreases in fertility rate coincide with continuously progressing economic growth. The situation changes diametrically at higher HDI levels. Further development, upon reaching a particular threshold, may lead to a reversal in fertility declining trend. The level of HDI, which turns the correlation between human development and fertility from negative to positive, is at about 0.9. Following the above, they predict that, in long-run perspective, advanced in human development shall impact positively fertility rates; however changes in fertility are not exclusively attributed to economic effect solely. Changing relationship – from negative to positive – between two covariates like total fertility rates and economic development, can be graphically approximated by U-shaped pattern. Luci and Thévenon (2010) also report on U-shaped relationship between TFR and GDP per capita. Unlike Myrskylä et al. (2009) do, they analyse the impact of GDP per capita on fertility rates, to isolate the pure economic impact on total fertility rates. To test the hypothesis of a convex impact of GDP per capita on TFR, Luci and Thévenon (2010) use a panel data set of 30 OECD countries over the time span 1960-2007. Applying one step-estimator, they designate turning point in the relationship between economic growth and fertility, at which further growth may lead to a reversal of fertility decline trend. The minimum of the curve is located at specific GDP per capita that corresponds to approximately 32,600 (in constant 2005 US\$) and total fertility rate at 1.51 children per woman. Separately they identify country-specific factors, which intend to explain why countries at comparable level of GDP per capita levels experience different fertility rates. A general conclusion of the study is that economic develop-

stein et al. (2009), Frejka (2010), Sobotka et al. (2011), or Neels and de Wachter (2010a, 2010b).

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

ment is likely to induce the fertility rebound; however, the evidence is not robust and case-sensitive. The evidence provided by Myrskylä et al. (2009) clearly claims that advances in development path, in some cases are accompanied by reverses of declining fertility rate, but, by contrast, such conclusion is questioned by Furuoka (2009). Furuoka applies a threshold regression to examine the existence of the U-shaped fertility-development curve proposed by Myrskylä et al. (2009). He uses threshold HDI (indicated as 0.777) to divide the sample into two subsamples – countries with HDI level equal to or lower than the threshold value and those that exceed the threshold. Thus, the negative relationship between HDI and fertility rate was revealed both in the countries with HDI below and above the threshold, although in countries with high HDI, the negative relationship between covariates was relatively weak. It supports the supposition that countries placed in earlier phases on economic development are more likely to experience declining fertility rates, likewise, in high-developed countries it is just the opposite. The aforementioned evidence provided by Myrskylä et al. (2009) is additionally supported by Goldstein et al. (2010). They verify the importance of economic conditions for fertility trends, using data on unemployment rates and GDP growth in 27 OECD countries (regardless total fertility rates levels), over the period 1995 to 2008. However, they do not claim direct influence of unemployment on fertility, rather emphasising importance of current economic conditions on individual decisions on childbearing. Goldstein et al. (2009) find both unemployment and economic growth rates to be statistically significant predictors of prospected TFR. Another stream, both in theoretical and empirical research highlights the importance of distinguishing between short and long-run perspectives when analyzing TFR and GDP per capita relationship. Long-term analysis mainly focuses on macro-factors (on aggregate level) that determine observed changes in fertility, and such approach was presented in aforementioned studies. While short-term analysis – concentrate on examining the impact of business cycles (especially recession) on the period TFR, and refer to individual decisions that may influence changes in TFR (Sobotka et al., 2011). The majority of short-term analysis shows pro-cyclical relationship between fertility and GDP per capita. During recessions (approximated by GDP per capita declines, growth of unemployment rates etc.) fertility tends to decrease. Such evidence is presented, *inter alia*, in works of Lee (1990), Bengtsson et al. (2004), Martin (2004) or Adsera and Menendez (2009). Sobotka, et al. (2011) confirmed the pro-cyclical relationship between GDP per capita and fertility. They used changes in GDP per capita as a proxy

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

explaining recession and the period TFR as an indicator of fertility (they imposed 1-year lag in GDP per capita impact on TFR changes). Their study (Sobotka et al., 2011) covered 26 low fertility developed countries over the period 1980-2008, and results obtained seem to support the hypothesis that fertility and economic growth are positively correlated along business cycles, which was already concluded from previous works (see i.e. Lee, 1990; Bengtsson et al., 2004). However, detecting rigid regularities in behavior of TFR versus GDP per capita if business cycles are considered, huge uncertainties emerge which makes the relationship even fuzzier. The previous was clearly stated in works of i.e. Kohler et al. (2002a, 2002b), Santow and Bracher (2001), Mills and Blossfeld (2005), Kreyenfeld (2010), Neels (2010) or Sobotka (2010). Circumstance that today's recessions (i.e. that which started in 2008) take place under, differ significantly from those in the past. This is mainly due to huge increases in women's active participation in labor market, which is partly determined by their growing access to education, contraceptives, and changing social norms. In effect, the previous may precondition the strength of influence of short-term recessions on changing fertility trends. The counter-cyclical relationship was only mentioned in few studies – i.e. Butz and Ward (1979a, 1979b) or Macukovich (1996). Recent decades are featured by relatively short recessions, thus their real impact on fertility was temporary. The fall of fertility during recessions was followed by its rise (or slower decline) during recoveries. When analyzing trends in fertility in short time perspective, there might arise, some difficulties with clear distinguish between fertility changes and fertility timing (postponement of the birth). Only in few studies, we observe a trial to tackle the problem just mentioned. Formal analysis trying to combine short and long run perspective in detecting relationships between economic development and fertility, are found i.e. in works of i.e. Ogawa (2003) or Rindfuss et al. (1988). Empirical evidence linking fertility changes with GDP per capita is even rarer than the previous. Our empirical analysis, presented in following sections of the paper, predominantly concentrates on detecting long-term relationships between changing total fertility rates and GDP per capita.

Data

Intentionally, our analysis is limited to two variables. Firstly, we account for Total Fertility Rate (TFR_{it}) which refers to number of children that a woman would give birth to, in accordance with current age-specific

fertility rates (see WDI 2013). Secondly, to approximate level of economic development of countries, we consider gross domestic product per capita ($GDP_{pc_{it}}$). We take natural logarithms of national GDP per capita in constant 2005 US\$. All data are exclusively derived from World Development Indicators database 2013. To complete our empirical analysis we construct strongly balanced cross-country long panel including 18 high-income economies that satisfy two prerequisites: over the period 1970-2011 Total Fertility Rate has dropped below 2.1 (replacement rate) which was followed by 'fertility rebound', and – according to World Bank – are classified⁴ as high-income countries. Finally, the empirical sample covers Australia, Belgium, Barbados, Canada, Switzerland, Germany, Denmark, Spain, Finland, France, United Kingdom, Greece, Japan, Italy, Netherlands, Norway, Sweden and the United States.

Methodological settings and empirical targets

The aim of the paper is twofold. Preliminary, using panel data of 18 countries over the period 1970-2011 we are to confirm the hypothesis on U-shaped relationship between Total Fertility Rate and economic growth approximated by GDP per capita. Following the above, we estimate threshold level of GDP-threshold when the fertility rebound effect is revealed. To test the hypothesized relationship, we perform panel regressions analysis, which allow capturing variation in behavior across time and entities (countries), if countries tend to be highly heterogeneous. Firstly we confirm the U-shaped relationship between variables: Total Fertility Rate (TFR_{it}) – response variable; and economic growth ($\ln GDP_{pc_{it}}$) – explanatory variable. For this, adopting pooled OLS, we examine linear model versus 2-degree polynomial (quadratic equation) and 3-degree polynomial (cubic equation). To formalize the above, we specify:

$$TFR_{it} = \beta_0 + \beta_1 \ln GDP_{pc_{it}} + \varepsilon_{it}, \quad (1)$$

$$TFR_{it} = \beta_0 + \beta_1 \ln GDP_{pc_{it}} + \beta_2 (\ln GDP_{pc_{it}})^2 + \varepsilon_{it}, \quad (2)$$

$$TFR_{it} = \beta_0 + \beta_1 \ln GDP_{pc_{it}} + \beta_2 (\ln GDP_{pc_{it}})^2 + \beta_3 (\ln GDP_{pc_{it}})^3 + \varepsilon_{it}, \quad (3)$$

⁴ According to formal World Bank country classification (see: <http://data.worldbank.org/about/country-classifications>, accessed: Feb 2014)

where i denotes country, t – period (year) and ε_{it} – an error term. If U-shaped relationship between TFR_{it} and $\ln GDP_{pc_{it}}$ is confirmed, afterwards we exclusively concentrate on quadratic longitudinal models. Using yearly observations, we test convex shape of the curve explaining cross-country relationship between TFR_i and $\ln GDP_{pc_{it}}$ and its square term. To capture time-invariant countries' specific effects, we propose country-fixed effects regression, defined as:

$$TFR_{it} = \alpha_i + \delta_1 \ln GDP_{pc_{it}} + \delta_2 (\ln GDP_{pc_{it}})^2 + \varepsilon_{it}, \quad (4)$$

which can be rewritten (if country-dummies included):

$$TFR_{it} = \alpha_i + \delta_1 \ln GDP_{pc_{it}} + \delta_2 (\ln GDP_{pc_{it}})^2 + \gamma_2 C_2 + \dots + \gamma_n C_n + \varepsilon_{it}. \quad (5)$$

In Eq.(4)-(5), α_i denotes unobserved, time-invariant fixed effect, γ is coefficient for binary-country regressors, C – is country-dummy, n accounts for number of countries in the sample, and α_i and $(\ln GDP_{pc_{it}})$ are arbitrary correlated. For Eqs.(4)-(5), to satisfy the exogeneity assumption, we assume that $E(\varepsilon_{it} / X_i, \alpha_i) = 0$, if X_i represents $(\ln GDP_{pc_{it}})$. In specified model, the TFR_i concisely expresses the vector of country's individual results determined by changes in *per capita* income, across all periods. To examine time-fixed effects we additionally estimate:

$$TFR_{it} = \alpha_i + \delta_1 \ln GDP_{pc_{it}} + \delta_2 (\ln GDP_{pc_{it}})^2 + \gamma_2 C_2 + \dots + \gamma_n C_n + \lambda_2 Y_2 + \dots + \lambda_n Y_n + \varepsilon_{it}, \quad (6)$$

where Y is year-dummy and λ stands for its coefficient. Hence regression Eq.(6) is estimated for $n - 1$ countries and $y - 1$ years. In Eq.(6) we relax the assumption on unobserved effects which vary across countries but are constant over time. Thus we control for time effects supposing that unexpected variation potentially influence explanatory variable.

To confirm results generated from Eqs.(5)-(6), along with within estimator we introduce instrumental variables (IV) estimator, which cuts potential correlation between error term and explanatory variables. To formalize the above, let us give: $y_i = \beta x_i + \varepsilon_i$, but $E(x_i, \varepsilon_i) \neq 0$, despite the exogeneity assumption requires $E(x_i, \varepsilon_i) = 0$. Hence, to "omit" the endogeneity, we define z_i as instrument which satisfies $E(z_i, \varepsilon_i) \neq 0$ and $E(z_i, x_i) = 0$. To obtain unbiased β , we adopt 2SLS method where: $y_i = \beta x_i + \varepsilon_i$ and $x_i = \varphi z_i + \mu_i$, if $\varphi \neq 0$ ($\Leftrightarrow E(z_i, \varepsilon_i) \neq 0$). We also

deploy lagged $\ln GDPpc_{it}$ and $(\ln GDPpc_{it})^2$ ($\ln GDPpc_{it}$ – 1-year lag), $(\ln GDPpc_{it})^2$ – 1-year lag) as instruments, which are sufficiently correlated with $\ln GDPpc_{it}$ and $(\ln GDPpc_{it})^2$ respectively, but uncorrelated with ε_{it} , which allows producing unbiased δ_1 and δ_2 . To get rid of the unobserved heterogeneity in models, first differences estimators (FDE) are often applied. However, we decide not to follow this approach. First differencing of data implies that all estimates are generated for relative changes instead of levels, which brings risk of obtaining misleading results due to convergence process that characterizes analyzed countries. Convergence hypothesis support the logic that relatively poor economies experience higher rates of i.e. GDP per capita growth, if compared to rich ones. In our case, as total fertility rate are expected to decrease along with economic growth, which results in positive correlation between variables expressed as relative changes of both $\ln GDPpc_{it}$ and TFR_{it} . If we assume the previous, concluding on the role economic growth in total fertility rate in-time variability might be confusing and leading to incorrect conclusions. Luci and Thévenon (2011), they also refer to the problem and indicate that using FD estimator in this case might not allow for clear statement about the ‘role of economic development for the fertility rebound in highly developed countries’ (see Luci and Thévenon, 2011).

To accomplish second goal of the paper we calculate the vertex (turning point) of the parabola defined as in Eq.(2), which corresponds to averaged level of GDP per capita at which the fertility rebound takes place. If we assume that Eq.(2) is a 2-order polynomial, then its general form follows:

$$f(x) = ax^2 + bx + c , \tag{7}$$

where $x \in (-\infty; +\infty)$ and at least $a \neq 0$.

Thus the vertex (turning point) of the Eq.(7) is defined as:

$$\left(-\frac{b}{2a}, f\left(-\frac{b}{2a}\right) \right). \tag{8}$$

Alternatively the (8) can be calculated by use of first derivative of (7):

$$f'(x) = 2ax + b , \tag{9}$$

and solving the equation:

$$f'(x) = 2ax + b = 0 . \quad (10)$$

The solution of Eq.(10), returns estimates level of GDP per capita corresponding to the threshold at which the relationship between TFR and GDPpc turns to be positive instead of negative.

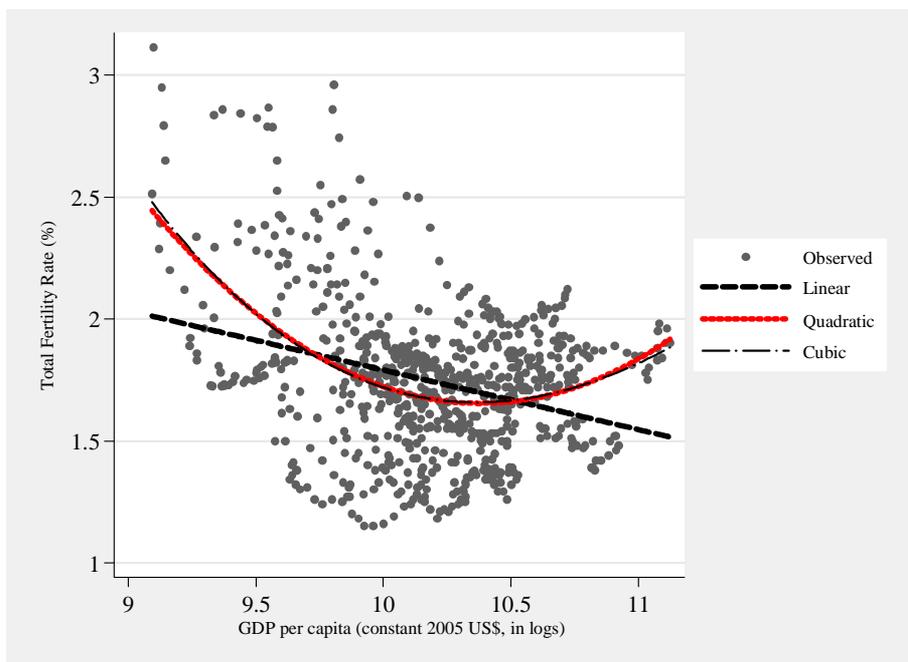

Results

As it was explained, our empirical analysis is limited to countries where the fertility rebound was detected over the period 1970-2011. Finally have concentrated on 18 high-income economies, where total fertility rate fell below 2.1 – replacement rate, and after reaching the low point it was steadily increasing. Although growing trends in total fertility rates were to a point disrupted by short “ups” and “downs”, the positive direction was maintained. Looking backwards, the reversal trends in TFR were preceded by long run and substantial falls in fertility rates. In 1970 the average total fertility rate was approximately 2.36⁵, then in 1980 – 1.77, 1990 – 1.69, 2000 – 1.60 and finally in 2011 – 1.70. Then the absolute change in average TFR between 1970 and 2000 was 0.76. Basing on the previous, we conclude that sharpest declines in total fertility rate were noted in decade 1970-1980, when the TFR fell below the threshold (2.1) required to replace country's population. Countries that experienced most significant declines in TFR over the period 1970-1980 were Barbados (-1.1), Netherlands (-.98), Australia (-.96), Italy and Norway (-.78 for both). Reversely, we note that in 2011, the average TFR was slightly higher than in 2000 (+0.1), thus over this decade the fertility rebound is revealed. Countries with greatest intensity of growing TFR over the period 2000-2011, were Sweden (+.36), United Kingdom (+.34), Belgium and Greece (+.13 for both) and Italy (+.15). Observed, over last decade, positive changes in fertility rates probably are becoming a permanent feature rather than mere cyclical change. However, the 41-year changes in total fertility rate do not resemble a smooth trend, but they are rather often interrupted by temporarily upward and downward trends. Furthermore, we confront total fertility rates versus economic growth. Our panel encompasses 18 countries covering long period, which constitutes a promise for accurate estimates. Adopted empirical procedures

⁵ Own estimates for the 18 selected countries.

allow controlling for both unobserved country and time specific effects. Relying on pooled OLS we detect the best-fitting curve demonstrating changes of TFR_{it} versus $GDPpc_{it}$. Additionally we plot our panel to control for graphical specification of examined relationship. Figure 1 preliminarily confirms that analyzed countries follow the U pattern over the period 1970-2011, if TFR_{it} versus $GDPpc_{it}$ relationship is examined. Solid black line (Chart 1 and 2) approximates theoretical pattern between TFR_{it} and $GDPpc_{it}$. For relatively low $GDPpc_{it}$ the TFR_{it} is high, but along with the process of economic growth it continuously declines, finally reaching the low point of the U-shaped curve (the parabola opens downward). Then having passed the vertex, moderate increases in TFR_{it} are revealed and the parabola opens upward. It supports the idea that the fertility rebound is accompanied by certain threshold level of $GDPpc_{it}$.

data, as $R^2=.196$ and all coefficients are statistically significant. Thus we conclude that quadratic model, better than linear or cubic, predicts relationship between TFR_{it} and $LnGDPpc_{it}$.

Note: in parenthesis *t*-statistics at 5% significance level.

Table 2 summarizes full specification of estimation results based on multiple periods in 18 selected countries. The analysis is based on panel data; hence the evidence demonstrates evolution of changing total fertility rates which are attributed to economic growth. Displayed outcomes suggest that TRF_{it} and $GDPpc_{it}$ are negatively correlated for lower per capita income (*ante* vertex of the curve), and the relationship turns to be positive for higher $GDPpc_{it}$, thus the U-shaped trajectory is generated. Estimates obtained from quadratic panel regressions of total fertility rates against economic growth; show that regressor ($lnGDPpc_{it}$) always holds negative sign, and $(lnGDPpc_{it})^2$ – positive. In all cases estimated coefficients are statistically significant at 5% level. In columns (1) and (2) results of simple OLS are reported. Model with $(lnGDPpc_{it})$ - 2-year lag variable added, shows slightly higher R-square, which might suggest that level of total fertility rate in period (t) is to some extent pre-conditioned by GDP per capita in period (t-2). Estimates were also performed with $(lnGDPpc_{it})$ - 1-year lag included, they were significantly weaker than for 2-year lag. This also sup-

ports the hypothesis that positive effects of economic growth on total fertility rates are revealed with significant time lags.

Source: own estimates based on data derived from World Development Indicators 2013. Note: below coefficients – robust SE. Also tested for (LnGDPpc_{it} - 1-year lag) – results less significant than for (LnGDPpc_{it} - 2-year lag). All estimates for significance level at 5%. ^(a) – bootstrap SE (1000 replications). Lagged explanatory variable used as instruments. (I) – country-fixed effect. (II) – time-fixed effects. (III) – instrumented country-fixed effects regression. (IV) – instrumented time-fixed effects regression.

Estimates of coefficients δ_1 and δ_2 resulted from within-estimator (FE(I)), explaining mediated effects of $\ln GDPpc_{it}$ on TFR_{it} due to cross-country differences, are statistically significant however – in each case – δ_1 tends to be higher than δ_2 . It suggests that, over the period 1970-2011, the “negative” relationship between TFR_{it} and $GDPpc_{it}$ was strongly dominant. As in case of OLS estimates, inclusion of lagged $GDPpc_{it}$, resulted on slightly higher R² of the model (.487), which again confirms lagged impact of economic growth on changes in total fertility rates. Analyzing relationship between total fertility rate and economic growth, we suppose that the impact of $GDPpc_{it}$ on TFR_{it} may be additionally determined by factors varying across time. Hence, to check for unexpected in-time variation, which potentially affects influence of GDP per capita on (TFR_{it}), we control for time-fixed effects. Results obtained from FE(II) suggest that, after ‘absorbing’ the unobserved effects that vary across time and potentially determines the impact of $GDPpc_{it}$ on TFR_{it} , the strength and direction of the relationship remains at comparable level to estimates generated by FE(I). The R-square (within) of the model FE(II) is at 0.59, thus we may conclude that

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

the FE(II) regression – with time-fixed effects included – relatively better explains relationship between total fertility rate and economic growth, than the FE(I) model. In FE(II) with lagged $GDPpc_{it}$ included, estimated coefficients, also confirm previous results and proof that relationship between total fertility changes and economic growth in examined panel, is *not* specifically featured by country and/or time fixed effects, but rather is *inter-temporal* in its nature. However, to confirm the previous, we additionally run random-effects regression (results not reported in Table 2) and perform Hausman test, which resulted in obtaining $Prob > \chi^2 = .000$, however the $V_b - V_B$ matrix is not positive definite. It suggests that relationship between total fertility rate and economic growth, to some extent, might be additionally affected by omitted variables relatively constant over time, but varying across countries, and – some other variable relatively constant (fixed) for countries but varying over time. To control for potential endogeneity in models, in columns (7) and (8) we present results of instrumental variables estimator. All coefficients are reported under assumption that lagged $(\ln GDPpc_{it})$ and $(\ln GDPpc_{it})^2$ are treated as instruments, and IV-regression was performed using 2SLS. Obtained outcome are highly similar to those resulted from estimates with no instruments used, thus are not discussed in particular. Presence of time-invariant country specific effects, like i.e. culture, institutions etc., surely influence relationship between TFR_{it} and economic growth, but their impact is not strength enough to eliminate average response of TFR_{it} if GDP per capita changes in analyzed countries over the period 1970-2011. Hence the ‘panel effect’ is not interrupted by occasional incidents. However to some extent, our results seem to be, additionally conditioned by unobserved effects that tend to vary in-time (not only across countries). The later justifies why variations in GDP per capita influence differently total fertility rate (determined by people’s behavior) at different points of time; and explains changes in patterns of total fertility rate over the period 1970-2011, as its significant falls are followed by moderate increases. Similar conclusions are presented in works of Luci and Thévenon (2011), Myrskylä et al. (2009) and Furuoka (2009). As the demonstrated in Figure 1, the relationship between total fertility rate and economic growth follows the U-shaped pattern, which is well described by quadratic models (confirmed by results presented in Table 2 above). The U-shaped patter approximated by quadratic function, yields existence of specific minimum (convex of the parabola), which depicts the threshold level of GDP per capita at which total fertility rate starts to rise and the downward trend is halted. Following previous estimates, the low peak of

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

the curve (using OLS) corresponds to approximately $\ln \text{GDPpc}_{it} = 10.38$ which is equivalent to 32 208 of GDP per capita (in 2005 constant US\$). Thus, when considering total fertility rate that changes as countries advance in economic growth, rising fertility trends tend to be revealed once a country achieves the threshold level of GDP per capita 32 208 (in 2005 constant US\$). The examined effects of economic growth on changing total fertility rates explain the *averaged* response of falling/rising TFR_{it} as GDPpc_{it} grows in *hypothetical* country. It shows that economic growth might be one of the channels inducing increases in total fertility rates. However it shall be bearded in mind that the study predominantly unveils the statistical relationships between TFR and GDP per capita.

The conclusions from the study are intentionally kept on general level; hence provide only a partial answer to the fertility rebound determinants. Keeping the rigid supposition that detected fertility rebound was exclusively driven by growth of national output, is based on weak foundations. The empirically based evidence shows that certain high-developed countries reached the turning point in total fertility (once have decrease below replacement rate, the TFR increases), which hopefully designates structural shifts both in terms of economic and social conditions (Barlow 1994, Brander and Dorwick 1994, Galor and Zang 1997, Dahan and Tsiddon 1998). However, country's specific effects and patterns explaining behavior of total fertility rate versus economic growth may differ significantly (Thevenon 2009, Goldstein et al. 2013), as being affected wide array of factors. The root causes of emerging positive relationship between TFR and economic growth may be traced in technological progress and women's better access to mass education (Becker et al., 1994; Frejka, 2012; Ní Bhrolcháin and Beaujouan, 2012), which allows for increasing number of people engaged in formal market activities and multiplying returns from labour (Bacci, 2013). Structural reorientations, like i.e. shifts from agricultural to industrial economy, or emergence in service-based economy and labour force feminization (Schaller, 2012), are other recognized determinants of fertility declines. As number of women involved in labour force grows, they are less determined to bear children. Intensity of changes in social attitudes, religion, income inequalities (Repetto, 2013), or state policies designed toward fertility increases (Alesina and Rodrick, 1994; Parr and Guest, 2011), may potentially affect social norms or individual fertility choices (Barro and Becker, 1989; Wang et al., 1994; Hin et al., 2011; Orsal and Goldstein, 2011; Neels et al., 2013a; Neels et al., 2013b). The later, may induce trends reversals in countries' fertility rates. Additionally, there

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

also raises a question whether the observed growth in TFR is permanent or rather temporal. The uncertainty in the case is huge. Possibly the temporal increases in fertility rates are a direct consequence of demographic trends and the new 'fertility transition' might be the case. Or, alternatively, modest increases in TFR which are observed in different countries are the positive 'response' to pro-natal state policies, which are broadly incorporated in countries affected by low fertility. The later, probably, is rather to be answered in long-term horizon, as a 'combined response' of demographic and socio-economic changes (Galor and Zang, 1997; Schultz 2001; Bloom and Finlay, 2009; Cervellati and Sunde, 2011).

Conclusions

The paper was designed to uncover the relationship between changing total fertility rates and economic growth in 18 high-income economies over the period 1970-2011, and to depict the GDP-threshold at which the fertility rebound emerged. We have examined the relationship adopting longitudinal analysis, which allowed obtaining averaged response of total fertility rates as countries advance in economic development pattern. Additionally, it was hypothesized the U-shaped trajectory explains changes in long-run total fertility trends determined by economic growth, and the supposition was confirmed. Our estimates lead to general conclusion that TFR_{it} and $GDP_{pc_{it}}$ are closely interrelated, and uncovered quantitative relationship that supports the hypothesis on inter-temporal nature of the links. Hence, the relationship between total fertility rate and economic growth is relatively robust to time and country specific effects. We have also discovered that the fertility rebound is especially to be revealed as countries achieve the threshold level of economic development approximated by GDP per capita 32 208 (in 2005 constant US\$). Designating the turning point at U-shaped curve would imply that economic growth to a certain point constitutes a channel of reversing paths with regard to total fertility rates in high-income countries. The last supports more general idea that countries at higher stages of development tend to experience fertility rebound as per capita income is sufficient to provide decent life and education for more children (Varvarigos, 2013). It may also suggest that some of developed countries are now entering new phase of development significantly marked by demographic change determined by reversals in fertility rates, which starts to recover and grow slightly above pure replacement rate. Although discovering such quantitative links between TFR and GDP per capita, we do not

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

claim that achieving the threshold GDP per capita shall automatically induce increases in total fertility rates. Surely, not all countries will follow analogous paths of growing fertility, regardless they perform well or not in terms of economic growth. Additionally, the positive impact on growing income on fertility may finally be to be temporal and short-term. Still many developed countries do not experience the fertility rebound, which suggests that economic growth does not drive exclusively demographic changes, and fertility rebounds across countries are only partly explained by growth in living standards, while the rest of it is hugely attributed to institutional, social and state policy context.

How to Effectively Support Export Activity

JEL Classification: *F10; F23; F40*

Keywords: *exporter; export activity; support; heterogeneous firms*

Abstract: Exports is crucial for every economy. It influences the level of economic growth, balance of payment and social welfare among many others. Therefore increase in exports becomes one of the main objectives of each government. This raises the question of how to support export activity in order to ensure the expected increase in exports. The aim of this paper is to investigate whether to support export activity at all and if so, how to do it effectively. To achieve the aim of the article the author analyzed both Polish and foreign literature, with special emphasis on the newest trade theories. Author analyzes secondary data describing factors that determine export activity, describe profile of a company becoming an exporter and investigate actual connection between offered support and increase in export activity.

Introduction

Export is of great importance for the economic development of the country and thus to the welfare of the society. It not only allows countries to exploit their comparative advantage and but also ensures greater variety of goods and competition and allows to benefit from scale economies. It influences the level of economic growth and balance of payment among many others. Exporters are believed to be more competitive and more productive, to generate more profit and to provide more employment than non-

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

exporters. That is why exporters are perceived as especially important for the economy. It therefore seems a justified desire to create government programs to support and advance the growth of exports. Increase in export becomes one of the main objectives of each government, despite the fact that gains from trade are rather unevenly distributed both within and between the countries. This results in various attempts to encourage companies to export by offering both direct and indirect support. The desire to promote and encourage export is an universal goal but achieved differently depending on the country. Government may support export directly with lending schemes for exporters¹, direct export subsidies or estimating offices assisting exporters in selling abroad. Bernard and Jensen (2004) noted that all fifty US states have such offices. Support might also take an indirect form of supporting productivity through various research & development programmes, training or consulting services. But in order to successfully support export it must be clear who the exporter is and what the reasons for exporting are. Numerous theories of trade are meant to answer these questions.

The aim of the following paper is to investigate whether to support export activity at all and if so how to do it effectively. In order to achieve this aim both Polish and foreign literature was analyzed, with special emphasis put on the newest trade theories including the model by Melitz (2003). Secondary data describing factors that determine export activity, describe profile of a company becoming an exporter and investigate actual connection between offered support and increase in export activity were analyzed.

The first part of this paper reviews the main international theories explaining trade and the exporters' role in the economy to then specify an exporter's profile which is needed to realize who the potential recipient of export support is. It then analyses the studies attempting to evaluate programs enhancing export activity. The paper finishes with an answer to the question: how to successfully support exports? Although there has been many studies on export promotion there is little empirical evidence proving its effectiveness.

¹ Direct Lending Scheme developed by UK Export Finance (the UK's official Export Credit Agency) is one of the examples. It was announced by the Chancellor of the Exchequer in the 2012 Autumn Statement and is available till March 2016. Up to £1.5 billion funding is provided. See: <https://www.gov.uk/government/news/direct-lending-scheme-launched-to-support-uk-exporters>

Theoretical basis for international trade

There are three main purposes of trade theories. First would be to explain the observed trade based on information about the characteristic of countries that trade. The second is to investigate the effects of trade on the economy and the third one to provide knowledge needed to evaluate a proper trade policy. It must be underlined that although substantial developments concerning trade theory have been made, they are not that substantially reflected in modern trade policy.

There has been a significant shift in attitude towards theories of trade. Macroeconomic approach has been complemented with a microeconomic one. There are three main groups of trade theories: traditional, New Trade Theories and so called New New Trade Theories. Traditional trade theories discussed trade between countries, new trade theories concentrated on trade between sectors whereas new new trade theories consider trade on a micro level between companies. Traditional theories concerned trade between countries in terms of comparative advantage. The leading ones are two models, one by David Ricardo and the second one by Eli Heckscher and Bertil Ohlin. Ricardian comparative advantage arises from productivity differences whereas Heckscher – Ohlin's from differences in abundance of production factors. In Ricardian model there are only two countries and two products and each of the countries possesses different technology. It is assumed that there is only one factor of production – labor (fully employed) and workers might migrate between the sectors but not between the countries. There are no trade barriers or costs of transports. In Heckscher – Ohlin model there are two countries and two products but two factors of production (labor and capital). Again no trade barriers and costs of transports were assumed.

Assumptions made in both theories, that is: perfect competition and constant scale returns allowed to ignore the importance of companies in the international trade. What was strongly objected by researchers was that trade structure is often far from perfect competition. Moreover, although traditional theories explained interindustry trade they did not explain trade between developed countries and intraindustry trade, which was observed. Only in late 1970's so called New Trade Theories based on monopolistic competition were developed. Lancaster (1975), Spence (1976), Dixit and Stiglitz (1977) provided some insight into the behavior of companies in imperfect competition by creating models of intraindustry trade in differentiated goods. The essence of the New Trade model by Krugman (1980) are

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

the preferences for variety between and within countries, economies of scale and products that are differentiated. New Trade Theories presented trade in terms of sectors which helped to explain the observed intraindustry trade.

Despite the substantial evolution of trade theories, both “old” and “new” assumed a representative company. This approach ignored behavior of companies within the sector and their role in international trade. It seemed insufficient taking into account the variety of productivity, capital and skill intensity across companies. As a consequence so called New New Trade models were developed, emphasizing the importance of heterogeneity of companies for analyzing international trade. Two leading models emerged. First one – the BEJK model, was introduced by Bernard, Eaton, Jensen and Kortum (2003). They used random productivity of companies in multicountry extension of Ricardian model by Eaton and Kortum (2002). The second one, which now seems fundamental, was developed by Melitz (2003). He introduced the heterogeneity of companies into Krugman’s (1980) model describing intraindustry trade. Melitz’s model describes the demand similarly to Krugman’s and consumers’ preferences are consistent with the CES function (Hagemeyer, 2006). According to this model the company draws its productivity from a random *distribution* but only after paying the fixed market entry cost. This cost is thereafter sunk. There is an assumed level of productivity allowing a company to remain on the market, drawing productivity from below this threshold means being forced to exit. According to Melitz (2003, 2008) companies differ significantly, especially in terms of above mentioned productivity which is a key factor in internationalization of firms. Export turns profitable for the most productive companies only. For those in the middle local market would be the target, the least productive fall out of the market entirely.

In order to know who to support, potential exporters must be identified using the theoretical background provided. It is important to decide whether everyone interested in or engaged in foreign trade should be a recipient of government export-related support. It might also be helpful to differentiate help being effective in case of exporters from assistance positively influencing the nonexporters only.

The exporter's profile

As already mentioned export plays an important role in every economy due to enhancing employment or generating economies of scale, but it is relatively rare as an activity (Bernard, Jensen, Redding & Schott, 2007). There were 5 726 160 firms in United States in 2012 (according to United States Census Bureau) of which 221 067 exported and 83 800 both exported and imported (report U.S. Trading Companies, 2012). Majority of exporting companies belonged to the SMEs. In comparison in Poland out of 1 762 321 companies 110 424 export.

Table 1. Micro, small, medium and large companies in Poland and their export activity.

	Number of enterprises	%	Exporting	% of Micro/S/M/L
Micro*	1 710 598	97,1%	94 083	5,5%
Small	32 728	1,9%	7 272	22,2%
Medium	15 841	0,9%	7 075	44,7%
Large	3 154	0,2%	1 994	63,2%
Total	1 762 321	100,0%	110 424	6,3%

* Data for 2011

Source: Wołodkiewicz-Donimirski, Z. (2014), *Eksport małych i średnich przedsiębiorstw w 2012 r.*, Analizy BAS nr 1 (105), 2014 and Statistical Information and Elaborations, Financial Results of Economic Entities in I-XII 2013, Central Statistical Office, 2014.

This data proves how important small and medium enterprises are in terms of export, therefore their specificity should be taken into consideration when delivering export promotion programs. There has been many studies investigating the link between characteristic of companies and probability of becoming an exporting company. Size of the company was one of the analyzed factors. Studies proved that only some companies have necessary characteristics to become exporters.

Bernard and Jensen (1995) studied the relationship between exporting and the performance of plants. They used data from the Census Bureau's Annual Survey of Manufactures (ASM) for the years 1976-1987 and they found significant differences between exporters and nonexporters across the analyzed companies. According to them exporters performed much better than nonexporters in every investigated dimension. They were not only larger, but also more productive and more capital intensive. It was also

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

noted that wages in exporting companies were more than 14% higher. According to their research exporters have more employees, higher productivity and greater capital and technology intensity (Bernard & Jensen, 1995). Past success increases the probability of future exporting. Bernard and Jensen (1999) estimated that exporting today increases the probability of exporting tomorrow by 39% (Bernard & Jensen, 1999)

Roberts and Tybout (1997) noticed a positive correlation between propensity to export and plant size, age and structure of ownership. They notice that the size determinant may reflect Krugman's (1984) economy of scale in exports. Supporting the assumption that market forces select out the least efficient producers it is probable that the older the company is the more time it had to learn and gain cost advantages (Roberts & Tybout, 1997).

While investigating reasons for exporting it is important to remember that exporters might exit and nonexporters might enter exporting at any given time so the set of exporting companies undergoes continuous changes and is therefore more problematic to study. Bernard and Jensen (1999) state that there is a high degree of reentering by former exporters, so past performance and experience influence positively propensity to export. In another of their studies Bernard and Jensen (2004) examine characteristics of companies, their size, labor force, entry costs, past performance in exports, effect of spillovers and efficacy of government interventions.

Government support in studies

Potential benefits from international trade, such as boosting growth and employment, explain the desire to build export promotion and assistance programs. It also justifies covering the expenditure mainly from public funds (Cansino, Lopez-Melendo, Pablo-Romero & Sanchez Braza 2013). It is however expected that public funds are always spent effectively and cautiously. This raises the question of how to evaluate the effectiveness of such support. There is a set of empirical studies investigating the possible ways of doing so. One of the most popular methods of assessing support programs is using a survey addressed to the recipients of such assistance, but usefulness and reliability of this method have been widely questioned. In their work, Cansino, Lopez-Melendo, Pablo-Romero & Sanchez Braza (2013) reported numerous objections to surveys, reflected in the literature. They are as follows:

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

- respondents might be reluctant to evaluate the program negatively, since many of them got in without any cost (Brewer, 2009),
- lack of understanding between government and SME concerning the role of support programs increases dissatisfaction reflected in the survey (Albaum, 1983),
- respondent's opinions are often to varied (Crick & Czinkota, 1995),
- subjectivity of the given answers making it impossible to draw balanced conclusions (Francis & Collins – Dodd, 2004).

Another approach reflected in research was to compare the expenditure on export promotion to export performance (both values aggregated). It was done by Armah & Epperson (1997), Richards et al. (1997) (Cansino, Lopez-Melendo, Pablo-Romero & Sanchez Braza, 2013). It was widely criticised mainly because it is not possible to indicate the share of export increase resulting from export promotion programs. Many other factors influence the volume of export and it is difficult to separate them from the influence of export assistance programs.

Cansino, Lopez-Melendo, Pablo-Romero & Sanchez Braza (2013) examine the possibilities of using statistical casual interference methods to perform an economic evaluation of increase in export directly attributed to export promotion programs. They suggest the use of Neymann-Rubin Causal Model (RCM) that allows to compare participants to non-participants in a public program, using a treatment indicator and a variable that will measure the effect of analysed policy (See also: Cadot, Fernandes, Gourdon, & Mattoo, 2012).

Bernard and Jensen (2004) name potential benefits of supporting and promoting exports. Reducing the market entry cost by helping to gather information on foreign markets could encourage export activity. Alternatively helping potential or current exporters to coordinate their actions could decrease the exporting cost and therefore result in increased volume of exports or increased number of exporters. The authors however found no significant impact of grants or subsidies on market entry. They suspect that the analyzed sample (large plants) might not be adequate to investigate, since most of the support is addressed to small and medium enterprises (Bernard & Jensen, 2004).

According to Francis and Collins-Dood (2004) programs enhancing export influence companies differently depending on the stage of export involvement. They concluded that in terms of short-time effects such support is of greater importance for beginners rather than for experienced exporters or nonexporters.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

Görg, Henry and Strobl (2005) investigated whether government support can cause an increase in export activity. Their main conclusion was that depending on the size of grant support it can intensify exports of companies being already exporters, however they found no evidence supporting the assumption that it can encourage non-exporters to become exporters. Not the very fact of receiving a grant is important, it is its size that really matters. The main problem indicated in the study is how to estimate the effect of government support since it would demand knowing what export would have been without this support. Using non-recipients as a comparison group would help if grants were given randomly which they are obviously not. Recipients are always chosen according to specific selection criteria that might additionally cause some companies to self-reject from the application process (Görg, Henry & Strobl, 2005). Brewer (2009) states that lack of consensus concerning evaluating export support among the researchers might have caused the decrease in number of studies on the subject.

Creusen and Lejour (2013) analysed the influence of economic diplomacy in the form of trade posts and trade missions on market entry. They noticed the impact of such support in case of middle-income countries, whereas no impact was found regarding higher-income countries. The study suggests that this type of support should focus on countries with high market entry barriers like developing countries regardless and not on the type of firm applying for assistance.

There is a long list of activities that might be implemented by governments in order to promote export. They range from providing publications concerning export and potential foreign markets, organizing workshops, assistance in trade exhibitions, help in organizing business visits overseas, enabling contact with potential business partners to offering subsidized loans (Brewer, 2009). Wide range of export – related support tools that is available, might reflect varying needs of companies depending on a stage of internationalization they are in, taking into account that each stage means different obstacles (Kotabe & Czinkota 1992, Brewer, 2009).

Conclusions

The very idea of supporting export seems indisputable. Majority of researchers and politicians would answer positively to the question whether to support export or not. They would also agree that support should be granted to a cautiously chosen group of companies. What turns out to be

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

problematic is what criteria to apply and how to evaluate the effectiveness of programs used. There is no consensus so far regarding those issues.

New New Trade Theories would suggest that government support should be addressed to companies that could be described by a set of characteristics, with a special emphasis on their productivity. According to Görg, Henry and Strobl (2005) supporting productivity may prove to be more effective than traditional export promotion programs. It would be advised to take a closer look at determinants of export activity in order to offer a purposeful export assistance.

It is also worth stressing that majority of statistical data is aggregated and according to New New Trade Theories international trade should be evaluated using panel data on companies, which is much more difficult to obtain.

The most problematic however, is measuring the effectiveness of the support provided. Apart from choosing the most adequate method it would be helpful to divide recipients into the groups according to the: size, level of internationalization and productivity and assess the results accordingly.

Determining Social Capital by Social Accounting

JEL Classification: *D1; D6; D61; M41; O15; Z130*

Keywords: *Social capital; Social success; Social accounting; Ex-post Analysis*

Abstract: Although social capital has been often debated in the last 20 years, there is a widely accepted definition missing and the approaches to measure its size are not very developed. Therefore, the definitions of social capital are stated and analysed, whether they are appropriately designed also for measurement purposes. We end up with a division between capital consisting of real capital as fixed and working capital and financial capital on the one hand and capitals, which are referring to human capital and social capital in a narrow sense on the other hand. The last two are named here as social capital. The stock of the first kind of capital can be expressed as net capital when the liabilities are deducted is booked to the final social balance as well as the remainder of the stock accounts. The stock of the second one can be identified as social assets reduced by social liabilities. Non-commercial values of economic activities are gathered in social accounting. With social accounting exist several approaches, however most of them are not developed to such an extent that the social capital can be determined through an adequate ex-post analysis. A welfare economic oriented approach comprising a bookkeeping system helps to determine social capital. Based on the willingness to pay approach a commercial bookkeeping system and an additional social bookkeeping were designed where the respective “private” and additional social capital were verified. Both together show the total social capital related to an economic subject. The result is illustrated by such a social accounting for the Faculty

of Economics and Business Administration of the University of Tartu for 2006. The author discusses the limits and possibilities of this kind of social capital determination.

Introduction

In many publications on development social capital is discussed as a development factor (OECD 2001). However, it is a rather vague concept (Bichmeier, 2002; Robinson, Schmidt, Siles 2002; Parts, 2009; Dill 2014) stemming from various sciences (Westlund, 2006; Parts, 2009), e.g. sociology, political science and economics, which implies extraordinary measurement problems (Franzen & Pointner 2007). Many measurement approaches are directed to measure social networks by network size indicators (Fukuyama, 1997; Parts, 2009), but they are not very useful for economic analysis, because of aggregation problems and missing economic evaluation (Dasgupta, 2002).

Therefore, the following questions are tackled:

- Which definitions of social capital make sense for economic analysis?
- How can they be measured?
- How to measure social capital in the framework of social accounting?
- Which bookkeeping system of social accounting leads us to measured social capital?

The first section of the article turns to the definitions and types of social capital. The second one deals with the difficulties of measurement. The third section tackles the possibilities of measurement by social accounting. A fourth section shows the measurement of social capital of a university faculty within a welfare oriented social accounting bookkeeping approach. A discussion of the possibilities and limits of this measurement approach brings our investigation to an end.

Methodology of the Research

The article is based on a literature review of definitions of social capital and attempts of its measurement. The literature on social accounting is examined in order to detect whether a welfare oriented social accounting approach exists, which allows a measurement of social capital to be developed. Recently, such a welfare oriented social accounting approach was developed that comprises an ex-post analysis, an appropriate accounting and bookkeeping system (Schmitz, 1980; Tsimopoulos, 1989; Friedrich

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

1991, 2010; Eerma & Friedrich, 2012; Eerma, 2014). This approach was developed by the author and his fellow researchers. An ex-post analysis was formulated, the charts of accounts were defined, and evaluation methods for social benefits and social goods were determined and bookkeeping procedures elaborated. The approach was applied to the Faculty of Management and Economics of the University of Tartu to identify social success of the faculty for 2006. The reader is introduced into this approach and the measurement techniques to determine social capital.

The limits of this kind of social accounting to determine social capital – in particular related to the welfare theoretical basis - are mentioned and discussed. The author indicates further developments of this social capital measurement approach.

Problems of applying this approach as a management tool, the ways how it could influence the management decisions in a university, CGE-impact models etc. are not tackled in the framework of this article.

Definitions of Social Capital

The definitions of social capital are manifold. Westlund (Westlund, 2006, p.8) defines social capital as “social, non-formalized networks that are created, maintained and used by the networks’ nodes/ actors to distribute norms, values, preferences and other social attributes, and characteristics, but which also emerge as a result of actors sharing some of these attributes”. Therefore, social capital constitutes of a network with links and nodes. It is like an infrastructure (Westlund, p.8). Information, goods, etc. (flows) are transmitted and the nodes can represent actors (Westlund, 2006; Grüb, 2007). In economic terms they may consist of economic units (households, private or public firms, public offices) or groups of economic units as the household sector, firms sector, state sector, etc. or groups defined according to other criteria. It also may refer to the whole economy. Alternatively it might be examined more generally through individuals in society, groups of them, organisations or the civic society or the society as a whole. One of the problems is that some authors concentrate on non-formalised networks. However, most important networks are formalised ones reflected in private and public law. On the one hand they are not totally open and accessible to everyone because one needs knowledge and education to cope with them, there are preconditions to use them and on the other hand they are path dependent and in steady development. At the very least the part of them in change should be included. There are similar defi-

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

nitions like culture concentrating on shared values and beliefs (Casson & Goodley, 2000; Kaasa, 2013; Kaasa & Parts 2010) or by North (1990) on institutions reflecting the rules of social cooperation and organisations the players, without emphasising networks. Other authors include both and call them institutional capital (Hardin, 1999; Krishna, 2000). However, these attempts to define social capital are even vaguer. A special approach not often mentioned in literature was developed by Walter Isard and his fellow researchers (Isard et al., 1969). They defined a good more generally as a social good and transmitted microeconomics to social and political phenomena showing supply and demand for social goods such as votes, values, information, etc. thus including social capital as well. In the literature different kinds of social capital are mentioned as well such as human capital, social capital of different economic units, internal social capital of economic units and external ones, which are in special sectors like the public sector, civic society, and different spheres like political, social, and physical sphere (Westlund, 2006, p.39; Kaasa & Parts, 2010; Kaasa, 2013). With respect to the social sphere, social capital is interpreted as access to network based resources, generalized trust, or norms and values (Franzen & Pointner, 2007). Social capital has also a regional dimension which is institutionally related to and reflected in industrial districts (Paniccia, 2002), cluster (Steiner, 1998; Porter, 2000), regional information systems (Asheim & Gertler 2005), and triple helix (university-industry-government relations) (Etzkowitz, 2002). Social capital shows many effects on: the mentioned regions, civic society, markets, economic growth (Parts, 2009), groups, and single economic units, their establishment and development (Grüb, 2007; Tödting & Trippel 2012) on sectors, the public sector, shadow sector, resources like venture capital, environment, etc.

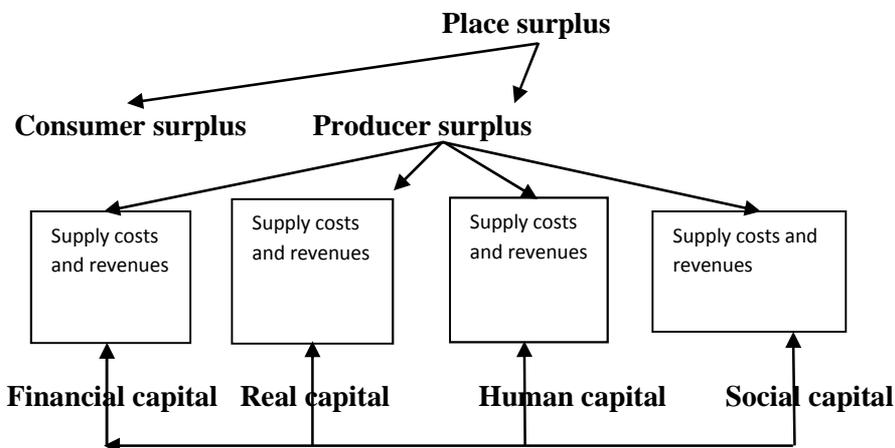

Social capital can appear in all parts of society such as civic society, governments, firms, households and it can be treated as a stock such as an investment. (Westlund, 2006, p.4).As mentioned above it causes many difficulties if it should be treated as a capital stock. Networks are difficult to measure and to add them up in total or in parts. There are inhomogeneous factors in links and nodes such as beliefs, values, etc. (Dasgupta, 2002) and there seem to be no prices to make the items to be aggregated comparable. Aggregation (Dasgupta, 2002) is mentioned as one of the main problems with social capital. Moreover, there are vertical networks between actors of higher and lower order such as EU, EU-member state, regional state, municipality, firm, or horizontal networks between actors of the same decision level (Westlund, 2006, pp 33), which greatly hamper aggregation

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

of social capital. On the other hand social capital has some features, which allows speaking about social capital. It shows vintages, it has to be maintained (Prusak & Cohen 2001), and it enables positive or negative impacts (Grüb, 2007) on economic units and change of social capital (Riemer 2005) and rewards (Glaesner, et al., 2002). At least time has to be allocated to maintain or establish social capital. These time expenses (Friedrich, 1978) lead to utilities from social capital and its use and to disutility because of opportunity utility losses.

These expenses can be also expressed in monetary form. As basis can serve the willingness to pay approach used in welfare theory can serve as a basis to express the advantages and disadvantages of a measure considering surpluses, external effects, distortions, etc. This is applied to identify the net-benefit of a measure or project, according to the Kaldor-Hicks test. According to such an evaluation of the advantages and disadvantages the rewards from social capital can be identified. Therefore, social capital shows also features of capital in an economic sense. This approach is similar to that of Bolton (2002) who defined a place surplus comprising a consumer surplus and a producer surplus concentrating on a firm. Westlund (2006) highlighted the influence of social capital on producer surplus through supply costs and revenues shown in Figure 1. The social capital influences human capital and both the real capital and human capital and the financial capital as well in such a way that supply costs and revenues change and producer surplus varies. Behind this is also the idea that the willingness to pay is expressed in the surpluses that reflect a welfare change.

Figure 1. Place surplus according to Westlund (2006)

Source: Westlund (2007)

However, it is not clear whose willingness to pay is measured, e.g. consumers inside and outside the place, how externalities related to social capital are expressed in revenues and cost especially those who occur outside the firm etc. and how this place surplus is separated from other place surpluses. Although the willingness to pay approach deals with total welfare in a national economy it is not shown how this place surplus is separated from those resulting from other firms or public offices the firm is cooperating with or linked in production. To differentiate between human capital and social capital is not easy. As far as human capital comprises the ability to know about and practice networks to gather information, to make decisions and communicate they are nearly not too separate. Moreover, one must exactly determine whether social capital welfare in the sense of the welfare of inhabitants of a country, region or municipality, of civic society of those jurisdictions should be identified. Social capital might also refer to the welfare of those economic units assigned to a sector such as public, private or a branch of industry, a group of firms, a group of households, to single firms, households, public offices, etc. Some times the authors distinguish between firm internal social capital, production-related social capital of the firm, environment-related social capital and market related social capital (Burt, 1992; Westlund, 2006). The place surplus concept tries to measure all of those.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

The most serious problem is that there are various and different attempts of measurement of social capital. Sociologists try to measure the network-based social capital with a name generator (Fisher, 1977; Bidart & Charbonneau, 2011). This instrument tries to measure the contacts to other persons. A position generator (Lin & Dumin, 1986) measures the contacts to persons who possess an important professional position for the questioned person. A resource generator (Van der Gaag & Snijders 2004) should serve to determine from which people he knows a person might receive resources. There are attempts to identify access to a network, to which individuals and actors pose as the function of a broker (Burt, 1984) and to which sub-groups exist (Grüb, 2007). The density of networks is also measured (Schenk, 1984). The density shows a relation between actual contacts and possible contacts (Haug, 1997). Moreover, attempts exist to measure trust (Schumacher, 2006) in other persons (Halpern, 2005) and in institutions (Paxton, 1999) by interviews or questionings. Measurement of norms, values and reciprocity happen by investigating the behaviour of players in experimental games (Diekmann, 2004). These sociological measurement procedures are mostly designed to describe social capital partly with respect to individuals.

Economists try to describe social capital by cases such as describing clusters, regression analysis with respect to the effects of social capital, and some impact analysis (Westlund, 2007) and policy investigations. Further literature exists on the wealth originating form social capital (Scrivens & Smith, 2013, Siegler, 2014) and on how technical knowledge is influenced by social capital (Gu, et al., 2013) and how networks change through economic behaviour (Jacson, 2009). An ex-post analysis including a welfare-oriented evaluation is missing.

Social Accounting as Tool to Measure Social Capital

Although since the last 40 years (Erma, 2014) there exist approaches to identify the contributions of single economic units to the success of society, the attempts to apply these instruments to measure and determine social capital are virtually non-existent. In particular, social capital as defined above has not been identified. There are social accountings for evaluations of projects using a welfare function, utility analysis or benefit-cost analysis implicitly considering the effects of social capital at present and in future (Erma, Friedrich, 2010, 2012, 2012a). Such social accountings are performed in particular for identifications of social success in environmental

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

accounting, health accounting and educational accounting. A comprehensive analysis of social capital is not involved. Social accountings concentrate especially on a statement of favourable and unfavourable social effects such as social audits (Schmitz, 1980). Some of them focus on special aspects of social life or factors of production such as human resource accounting in the sixties (Hermanson, 1964; Brummert, 1969; Flamholtz, 1971; Neubauer, 1974; Conrads, 1976). Other social accountings concentrate on contributions of a firm to social success such as corporate social accounting (Linowes, 1968; Abt, 1972; Monsen, 1972; Elliott-Jones, 1973, Eichhorn, 1974, Mühlenkamp, 2007). Some escape to a social indicator analysis, where the indicators signify social relevance and value (Dierkes, 1974; Mintrop, 1976; Fischer-Winkelmann, 1980; v. Wysocki, 1981; Schmitz, 1980; Friedrich, 1991; Schauer, 2007). Social capital is not explicitly detected. The human resource accounting directs the attention to human capital. However, social capital in the sense of networks is only evaluated indirectly, e.g. as special value of knowledge on social relations leading to higher human capital. Networks are considered in terms of social benefits transmitted to business partners and stakeholders, public jurisdictions, charity organisations, etc. However there is no identification of an item symbolising social capital. Mostly a welfare economic orientation is missing. Moreover, these approaches do not provide an ex-post analysis and a bookkeeping system necessary to identify the social success in a past period (Eerma, Friedrich 2010, 2012, 2012a; Eerma 2014). The link between social accounting and the determination of social capital does not exist.

Recently, have been some contributions which were not to identify social capital, but which enable to develop an ex-post analysis and bookkeeping system, thus providing a basis for a more comprehensive assessment of social impacts and values. This development started with Schmitz 1980, and developed through applications and extensions (Tsimopoulos 1989; Friedrich 1991; Friedrich, et al., 1993; Eerma & Friedrich 2010, 2012, 2012a; Eerma 2014) for public utilities, convention halls, university faculties, and other institutions like colleges and ecological banks. Moreover the bookkeeping system is welfare-oriented and a bookkeeping chart and bookkeeping and balancing rules have been developed. Therefore, we name it economic welfare-oriented social accounting

Therefore it should be discussed whether this bookkeeping assists to identify social capital. The basic features of this social accounting approach

have to be mentioned to show how the social capital is going to be identified.

Social Capital Assessed by Economic Welfare Oriented Social Accounting

The economic welfare called net-benefit is measured on the basis of the following evaluation in terms of willingness to pay^[1] in favour or against the impacts of activities of an economic unit (Friedrich, 1991; Eerma & Friedrich 2010, 2012, 2012a; Eerma, 2014)

Net benefit = consumer surplus +turnover + value positive external effects –producer surplus as distortion on factor markets- costs – value of negative external effects

The willingness to pay can be rearranged to

Net benefit = turnover - costs
(Commercial accounting)
+consumer surplus + value positive external effects – producer surplus as distortion on factor markets – value of negative external effects
(Additional social accounting)

A net-benefit increase means payments “social benefits” in favour of a measure show the + sign, whereas the willingness against “social costs” payments are marked by a minus sign. If the difference net benefit is positive a measure results as welfare increasing.

This shows that the willingness to pay can be detected by commercial accounting and by a supplementary social accounting. By aggregating the two parts of accounting one gains the total willingness to pay.

Direct social benefits and costs are measured directly by market-related items such as consumer surplus, turnover and costs related to the economic unit operations. Some social benefits and social costs are measured indirectly. Income increases, money value of time savings, decrease of costs, e.g. of self instruction, less compensation from insurance companies, reductions in contributions of other institutions, or higher values of shadow prices, higher values based on hypothetical demand functions (Dasgup-

¹ See the debate on willingness to pay evaluations in the debates on welfare theory (Graaff, 1963; Sen, 1982; Samuelson, 1983; Flores, 2003; Adler, Posner 2006).

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

ta *et al.*, 1972; Flores, 2003). Increases in property values and higher leases express higher ability to pay for external effects of economic unit operations because of improved services. Social costs incurred by the economic unit are determined by costs and input-oriented producer surpluses. Methods used to identify external social benefits serve to measure external social costs as well (Friedrich, 1991; Eerma & Friedrich 2010, 2012, 2012a; Eerma, 2014).

Social benefits existing in more than one period are stocks (social assets) and social costs existing in more than one period are stocks in the form of social liabilities. Those occurring in the period under consideration are current social benefits and current social costs (Friedrich, 1991; Eerma & Friedrich 2010, 2012, 2012a; Eerma, 2014). An adaptation of the chart of commercial accounts (revenues and expenses) serves for the commercial accounting to identify profit and stocks assets, liabilities - serves - and to gather social benefits and social costs reflected there.

Table 1. Accounting Groups

Group	Classification
Assets	0: material social assets, human social assets
	1: social cash
	2: social claims
Liabilities	3: social equity, adjustments
	4: social liabilities and social net benefit
Social benefits	5: social benefits
Social costs	6: social material and staff costs
Technical accounts	7: opening social balance, final social balance, social success operating statement
	8: deferral stocks
	9: deferral successes

Source: Eerma & Friedrich (2010, 2012, 2012a)

For the additional social accounts a chart has to show the current social benefits and current social costs and social benefits as stocks (social assets) and social costs as stocks (social liabilities). They are shown in Table 1. The additional social accounting also applies to double entry bookkeeping. Therefore there is a social cash account that assembles all the counter entries. Special deferral accounts are necessary to defer the social benefits and social costs that are caused by other economic units involved in transactions that mean the part of willingness to pay which is not due to the economic unit under investigation. In the chart appear social assets, social liabilities, cur-

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

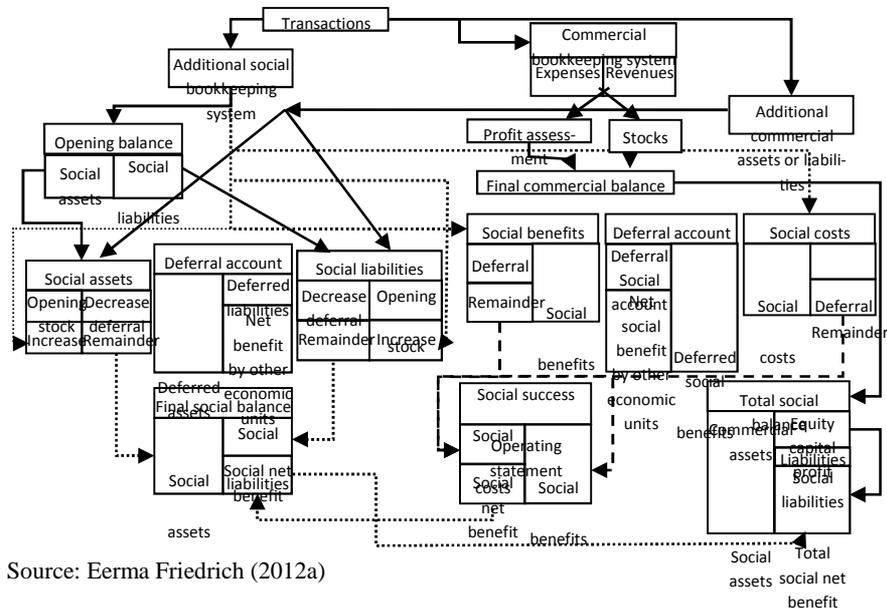

rent social benefits and current social costs. Moreover, there are technical accounts comprising opening balances, final social balance, final total social balance, the social success operating statement, and the deferral accounts for stocks and current social benefits and current social costs. The individual accounts show equations showing the remainder of an account or variable value at the end of a period, which is equal to the initial stock plus increases minus decreases (for details see Eerma, 2014). All individual accounts reflect a whole set of equations that are the basis for the ex-post analysis of the economic unit.

The stock accounts (respective equations are defined) according to types of long-lasting benefits (e.g. social assets). The current social benefits and current social costs are defined according to the operations of the economic unit.

Figure 2 shows the additional social bookkeeping and partly the commercial bookkeeping. In both parts an opening balance starts with the final stocks of the past period. With respect to the commercial part the revenues and expenses are entered in stock and current accounts. The remainder of the current accounts end up in the profit assessment account the resulting profit is transferred to the final commercial balance. There end up also the remainder of the stock accounts. In the additional social part some commercial stocks which are not considered in commercial accounting might be added. Then the transactions with respect to stocks are entered as well and deferrals take place. The entry of the transactions implying current benefits and current accounts follow. Deferrals are made. The remainders of the current social benefits and current social costs become collected within the social success operating statement and the current social net benefit determined. The latter is entered to the final social balance as well as the remainder of the stock accounts.

In a last step the final social balance and the commercial balance are aggregated to a total social balance. There we find the commercial assets and the social assets as well as equity capital, commercial liabilities, social liabilities, net social capital and current social success.

Figure 2. Economic Welfare Oriented Social Accounting

Source: Eerma Friedrich (2012a)

Therefore, this economic welfare oriented social accounting provides us with information about social capital. At first we receive information about the social capital related to the economic unit we are considering. When investigating the commercial part of the bookkeeping approach then we receive the private capital in the form of a net private capital. The real capital (fixed and working) and the financial capital are shown in the commercial balance. We also learn the net private capital, which is the former one reduced by the liabilities ending up as equity capital, reserves and profit – the profit would then be used for investments.

Social capital of the economic unit can be detected similarly. It results from the additional willingness to pay, which is not demonstrated in commercial bookkeeping. Therefore, it is related to all additional social entries of transactions connected to rents and the indirect evaluation methods. They include on the one hand internal social capital and the willingness to pay for it and partly the external social capital. However, an explicit division between human capital and other forms of social capital is not made. Here, the distinguishing mark is the kind of evaluation method to determine the willingness to pay. In practice human capital and other sorts of social capital are also difficult to separate. Knowledge about and integration into a

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

network can on the one hand reflect human capital but at the same time a network oriented social capital. Therefore, it seems wise to differentiate on one hand between the capital forms that are private ones just stated before and on the other hand social capital as the rest category that comprises the other forms as mentioned in chapter II. The economic welfare oriented approach allows detecting social capital of the economic unit. Net social capital results as the difference between social assets and social liabilities leading to the remainder of the social cash account representing net social capital plus the current social net-benefit. The willingness to pay approach is used to aggregate the different forms of social capital. These different forms of social capital vary from type to type of economic units according to the willingness to pay identification method applied.

Economic welfare oriented social accounting also enables to gather information about the social capital through the deferral accounts, which is due to the other economic units in an economy and also split into a stock component and a current component. However, it reflects social capital of total society, civic society, and of other sectors of economic units and the rest of the sector to which economic unit belong. The approach allows determining absolute levels but also changes of social capital. Through depreciation and acceleration and value adjustments it shows vintages of social capital. This approach also assists in specifying social capital by deciding on accounting needs to determine the period of ex-post analysis and by fixing the group of citizens whose welfare and social capital should be detected. Social capital also depends on the generations to consider, the region the analysis is concentrating on, the transactions and extension of networks considered, and the effects included. Social capital differs according to the evaluation methods of willingness to pay applied and to which kind of social capital is paid attention to. Moreover, the handling of alternative situations (with and without principle with respect to the economic unit), and the delineation of the economic unit (Erma & Friedrich, 2012a) influences the size of social capital.

**Social Capital of a University Faculty – The Example of the Faculty of
Economics and Business Administration of the University of Tartu**

Economic welfare oriented social accounting was applied to the Faculty of Economics and Business Administration of the University of Tartu (Erma & Friedrich, 2010, 2012, 2012a), and the Faculty of Mathematics and Computer Science of the University of Tartu (Erma, 2014). This so-

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

cial accounting was also performed in the European Colleges at Tartu, and the colleges at Pärnu /Estonia and Narva/Estonia related to the University of Tartu (Eerma & Friedrich, 2014). The approach described above was developed. From the year 2009 onwards the verification of the bookkeeping approach took place. The year 2006 was chosen for the empiric application for all faculties and colleges. One the one hand, that year was relatively stable with respect to the departments considered and on the other hand to gather objective data the information was not biased by ongoing managerial conflicts.

The competences, tasks, activities in teaching, research, consulting, etc. and their embeddings in networks within the university and with economic units outside the faculties and colleges were detected to delineate the basis to group the long-lasting social benefits and costs and to elaborate the current social benefit and current social cost account for the additional social accounting. The University of Tartu possesses a commercial bookkeeping system which is partly disaggregated to the faculty level and partly aggregated solely to the university level. Therefore, the commercial accounting has to be disaggregated – especially some stocks - and adapted to the faculties. A respective chart of accounts was assigned^{2[2]}. Thereafter, revenues, expenses, stocks, etc. were entered. The profits and losses were determined as remainder in the profit assessment account and a final commercial balance was provided (see also Figure 2 and Table 2). Here, we can learn about the “social capital“reflected as net assets (see Table 2).

The additional social accounting had to be developed totally from the scratch. The definition of social stocks leads to the stock accounts, which are listed in Table 2. The current social benefits and current social costs are shown in Table 3. The accounts follow the activities of the faculty. After entering the transactions and fixing the deferrals the values in table Table 3 derive. The additional social net-benefit appears as a remainder, which is transferred to the final social balance and from there to the total final balance (see Table.2). The stocks result, e.g. additional social assets and their value adjustments. Moreover, one finds the additional social liabilities and their adjustments too. The social capital in stock appears as a remainder of the social cash account. 42.387 EEK. However, social liabilities 0.0730 EEK are to be deducted. The additional social net-benefit shows social capital 25.084 EEK due to the activities of the faculty during 2006. It is an increase in social capital.

The social capital due to the involvement of other economic units can be learned from the deferral to the assets of additional social benefits amount to 2.875 thousand EEK. The difference between the referred current social net benefit due to the referred current social benefits and the referred current social costs amounts to 10.870 thousand EEK.

Chances and Limits to Detect Social Capital by the Economic Welfare Oriented Social Accounting

The Economic Welfare Oriented Social Accounting offers many chances to detect social capital. It combines and shows many aspects of social capital discussed in literature on social capital such as a stock, vintages, and maintenance activities. It comprises all specifications of social capital like networks, trust, values, norms, at least if there exists a willingness to pay for it. Therefore, it can be also aggregated. There is as well the possibility to identify the firm related social or the rest of it, which is linked to the firm's activities.

How far the social capital gets measured depends much on the evaluation methods concerning willingness to pay, which are applied to stocks and activities evaluation. Different methods may lead to different volumes of social capital. Here restrictions concerning data and methodological problems arise. This is especially relevant with respect to the indirect eval-

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

uation methods (Eerma 2014). One of the advantages concerns the comparability of the evaluations through willingness to pay.

Moreover, there is assumed that the demand curve shows the willingness to pay of the buyers. This is no problem if a final consumption good is offered, e.g. a study programme to students. With an intermediate product the analysis also assumes that the demanders firms and public offices are expressing their willingness to pay in the demand curve, in which also the willingness to pay of their customers is reflected. Therefore, no deferrals, etc. have to be made. However this problem has to be discussed more in detail⁴. If this assumption holds no social capital has to be considered in the framework of the commercial accounting.

The non commercial social capital not caused by the economic unit considered is expressed in the additional social accounting. The economic welfare oriented social accounting is especially applicable to measure the economic unit referred social capital.

However, some limitations are related to this tool to identify social capital. As the bookkeeping system uses welfare theory based evaluations it is related to the individualistic welfare theory (Graaff, 1963; Sen, 1982; Samuelson, 1983; Mishan, 1987, Adler & Posner, 2006). The role of social groups (e.g. administrators, trade unions, entrepreneurial associations) in determining the content of social welfare is seldom emphasized. Therefore, the values identified by the willingness to pay approaches do not necessarily reflect the true evaluation in society. Moreover, the assumption of constant marginal utility of money that means, ignoring the fact that an Estonian croon (euro) may stem from a rich or poor household, points to a strong assumption. Further debates concern the so-called compensation tests discussed in literature on welfare theory. However, the stated difficulties are also with other approaches to measure performance.

If the bookkeeping approach suggested for one Faculty should also be applied to several faculties and the University itself, or if it should be applied to other economic units the chart has to be adapted. Then, the conventions of deferral get evidently much more specific and complicated. Also the chart of social accounts needs further elaboration, when isolated

⁴ It has to be investigated whether all consumer surplus changes, turnover changes and cost changes with all economic units involved in production have to be included, whether it is sufficient to turn to value added, which in a national accounting is based on commercial accounting, by deducting the value added of the institution looked at from all economic units involved.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

social net benefits of the group of clients, such as types of students or of research clients, should be assessed. Some social benefits and costs are to be excluded. More group specific conventions to deferral of social benefits and costs have to be developed. Additional corrections of social benefits and costs, which are booked in commercial bookkeeping, have to be made and considered in the additional social accounting. Total social net benefit and total social assets and liabilities can be assessed in principle.

And last, but not least some efforts are necessary to complete the economic welfare oriented social accounting. All the bookings in the commercial part of the social accounting have to be checked whether they reflect really willingness to pay. With respect to the additional social part more sophisticated criteria to split social benefit and costs and to allocate them to the institutions causing the social net-benefit should be available. Then the identification of social capital becomes more precise. Further research is needed to improve the identifications of effects, the determination of depreciation rates for knowledge of students, scientists, researchers, professors etc., the assessment of consumer surpluses for individual services, methods to evaluate stocks and the allocation of pre-services to linked economic units. Charts have to be developed for different kinds of economic units.

The approach can be redeveloped to kinds of different social capital identifying approach according to types of evaluations. It must be determined, which evaluation methods are linked to which social capital type. Then the bookings for which the respective evaluations are used can be summarized in special accounts, which then show the types of individual social capital involved. In this way a supplementary bookkeeping would be introduced.

Another approach to identify social capital would be a bookkeeping system developed to measure different types of social capital. Then the chart has to be shaped according to the different types of social capital. An ex-post analysis of an economic unit for social capital would be designed. The transactions have then to be booked on accounts of different social capital and deferrals have to be made and booked. The different social capitals will emerge concerning social stocks, social liabilities and the current social capital caused.

A very demanding project would be not to start with the measurement of the individual social capital at the level of an economic unit, but to try to fix the total type of social capital in an economy or a region. However as the development of national accounting has shown this needs the develop-

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

ment of an individual social capital accounting first in order to assign an aggregated system of accounting^{5[5]}. That would enable also a place related determination of total social capital for a region or a location. Special deferrals or restricted aggregations criteria become necessary.

Conclusions

The social capital is a vague concept comprising networks, norms, values and actions of actors concerning these features. In literature the characteristics of social capital are debated. Different types of social capital exist at different levels, e.g. individual level, group level, civic society level and total society level. How far it has features of capital in an economic sense is under debate. Some authors discuss a division consisting of real capital as fixed and working capital and financial capital on the one hand and capital, which are referring to human capital and social capital in a narrow sense on the other hand.

Many economists are convinced of its importance, because of its effects on growth, innovation, management, types of markets, knowledge, etc. but the measurement of social capital as such is mostly done by sociologists. Attempts by economists are rather descriptive turning to practical cases, policy results or market developments or they turn to regression and other statistical analysis to identify the importance of social capital for some economic phenomena. However, measurement of social capital turns out unsatisfactory.

One possibility to measure social capital is yet not used. Social accounting serves to measure social impacts of economic activities. Several approaches of social accounting exist, however most of them are not developed to such an extent that the social capital can be determined through an adequate ex-post analysis. Most of them try to show the social and economic impacts of an economic unit in particular a firm on society. Only some special types of social capital of a firm can be identified. The usual social accounting have mostly no basis to aggregate different sorts of social capital or social capital at all. However, the welfare economic oriented approach of social accounting comprises monetary evaluations on basis of the willingness to pay approach applied in benefit-cost analysis and an ex-post

⁵ As an example serves the determination of the value added on the production account of national income accounting that results from aggregations of profit statements accounts from commercial bookkeeping.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

analysis that allows a bookkeeping of the relevant transactions occurring during a past period.

The definition of net benefit allows splitting social benefits and social costs in those which are reflected as revenues and expenses in commercial accounting and additional social benefits and social costs, which can be considered an additional social accounting which constitutes a supplementary bookkeeping. The results of both show the net commercial assets as difference between assets and liabilities plus the profit on the one side and the social capital as difference between the additional social assets reduced by social liabilities and the current social net benefit on the other side. This allows identifying social capital on the level of an economic unit.

The author demonstrates the basic features of the welfare economic oriented approach of social accounting of the Faculty of Economics and Business Administration for the University of Tartu in Estonia using data for 2006. How social capital of the faculty becomes expressed in the bookkeeping results has been explained. The social capital of the faculty turns out to be positive. It refers to networks, knowledge, values, norms and management actions. The part of social capital of the faculty that is not due to the faculty has been deferred. It refers to the additional social capital as remainder of the social cash account as a stock and the current social net benefit.

The welfare oriented approach of social accounting assists primarily to identify the social capital related to one economic unit. It also enables through the deferrals to estimate the part of social capital the economic unit is involved in that refers to activities of other economic units related to the economic unit under consideration. The approach does not inform about the total existing social capital in society, in a region or at a place. As the welfare economic oriented approach of social accounting was developed in order to detect social success, it is also not assigned to fix the amount of different types of social capital. Different social capitals are related to the different evaluation methods applied. Therefore, a next step of social capital identification, could lead to an extension of the approach by introducing a social capital oriented supplementary accounting where special remainders of accounts which are related to special types of social capital are transferred. An even more drastic extension would be when the total welfare oriented approach of social accounting is directed to entering the transaction within a chart of accounts which is defined according to different kinds of social capital. This, however, requires a totally new orientation of the whole approach.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

A measurement of the total social capital in society or region cannot take place within the social accounting directed to one economic unit. On the basis of social welfare oriented accounting for one unit similar to national accounting a framework for total social capital accounting has to be developed in future.

Limits of the welfare oriented approach of social accountings are due of the individualistic welfare theoretical basis of the approach, the weakness of the so-called compensation tests, the question how far the willingness to pay expresses social priorities, etc. Moreover, the approach needs further development with respect to deferral rates and depreciation rates, etc. and in particular to evaluation methods and possibilities to apply them and impact analysis. With respect to social capital a detailed analysis concerning the kind of social capital which is going to be measured when applying those methods is necessary.

**Using Genetic Algorithm in Dynamic Model
of Speculative Attack**

JEL Classification: *C6; F3; E5*

Keywords: *currency crisis; dynamic model; genetic algorithms*

Abstract: Evolution of speculative attack models show certain progress in developing idea of the role of expectations in the crisis mechanism. Obstfeld (1996) defined expectations as fully exogenous. Morris and Shin (1998) endogenised the expectations with respect to noise leaving information significance away. Dynamic approach proposed by Angeletos, Hellwig and Pavan (2006) operates under more sophisticated assumption about learning process that tries to reflect time-variant and complex nature of information in the currency market much better. But this model ignores many important details like a Central Bank cost function. Genetic algorithm allows to avoid problems connected with incorporating information and expectations into agent decision making process to an extent. There are some similarities between the evolution in Nature and currency market performance. In our paper an assumption about rational agent behaviour in the efficient market is criticised and we present our version of the dynamic model of a speculative attack, in which we use a genetic algorithm to define decision-making process of the currency market agents. The results of our simulation seem to be in line with the theory and intuition. An advantage of our model is that it reflects reality in quite complex way, i.e. level of noise changes in time (decreasing), there are different states of

fundamentals (with “more sensitive” upper part of the scale), number of inflowing agents can be low or high (due to different globalization phases, different capital flow phases, different uncertainty levels).

Introduction

Speculative attack models try to catch a complicated relation between information and expectations. Informed agents (provided by either private signals or common knowledge or both of these) formulate their expectations and due to these expectations make strategies either to attack or hold. This mechanism from information through expectations to attack has always been extremely difficult to cover in any theoretical framework. Evolution of speculative attack models show certain progress in developing idea of the role of expectations in the crisis mechanism. Obstfeld (1996) defined expectations as fully exogenous. Morris and Shin (1998) endogenised the expectations with respect to noise leaving information significance away. They proposed static model, including information but excluding any possibility of so-called common knowledge in the currency market. Dynamic approach proposed by Angeletos, Hellwig and Pavan (2006) operates under more sophisticated assumption about learning process that tries to reflect time-variant and complex nature of information in the currency market much better. But this model ignores many important details like a Central Bank cost function.

If we look at the speculative attack as at the optimisation problem, why not to use genetic algorithm to present the agent behaviour in the market? Genetic algorithm allows to avoid problems connected with incorporating information and expectations into agent decision making process to an extent. Evolution means that the species that are prepared to the environment worse, have smaller chances to survive, and as the time passes by, improved species appear. There are some similarities between the evolution in Nature and currency market performance. In the currency market the speculators make wrong decisions and are eliminated from the market by these speculators who generate high pay-offs. Therefore, we can assume that learning in the currency market may in fact be characterised like species adaptation process to the environment. That is why we believe that introducing genetic algorithm may be a right step towards finding some optimal solutions for the speculative attack model.

This paper is organized as follows. In the second section assumption about rational agent behaviour in the efficient market is criticised and we explain why we use genetic algorithm. In the third section dynamic model

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

of a speculative attack is presented. In the fourth section optimal strategies for the Central Bank and for speculators are defined. In the fifth section genetic algorithm that reflects decision making process is described. In the sixth section our results are presented. We also show evolution of a learning process. The last section contains conclusions.

**Critical approach towards rational agent behaviour
in the efficient market**

Foreign exchange market can not be characterised as a good example of strong efficiency paradigm by Fama (1970). Information is not equally available to all agents. The market is rather decentralised and trade transparency is low (see Lyons (2001)). It is well known, that this distinguishes the foreign exchange market from other financial markets. Moreover, results of the surveys (Sarno and Taylor (2002)), especially these based on the microstructural logic suggest that the static expectation hypothesis should be rejected. The results confirm heterogeneity of expectations.

Using behavioural finance perspective we can say that although an agent may store and process only a tiny part of the relevant information, the agent is not brainless. If we agree to abandon traditional rational expectation model that assumes perfect knowledge of the market participants, then it is possible to redefine an individual forecasting strategy, which is neither fully rational (in a sense of *homo oeconomicus*) nor fully irrational. It is in line with heuristics rules taken from the psychology. So-called *trial and error* strategy represents bounded rationality framework and means *ex post* checking how profitable certain rule is while comparing it with some others. If the rule does not prove to be the profitable one, then the agent switches to the better one. If the agent's strategy turns out to be successful, then she/he sticks to it. *Trial and error* strategy is rooted in Nature, it has got strongly evolutionary character.

In the behavioural model of exchange rate by De Grauwe and Grimaldi (2006) the mechanism of making forecasts by the agents is well described. The authors show that in the foreign exchange market the agents follow *trial and error* strategy, no matter if they are so-called "fundamentalists" or "chartists" (no matter if they analyse macroeconomic fundamentals or they rely on technical analysis to forecast the exchange rate). *Ex post* assessment of the forecasting strategies may transform "fundamentalist" into "chartist" or vice versa. It is worth mentioning that according to Tversky, Kahneman (1991) the agents need some time to adopt a new strategy, they are slightly

conservative, therefore “status quo bias” must be considered in their decision making process even though it is true that the agents react to the relative profitability of the rules. *Trial and error* strategy is thus a dynamic process that requires further assumptions concerning “memory” of the agent. De Grauwe and Grimaldi (2006) use the short-run memory hypothesis that implies that the agent refer just to last period’s squared forecast error to make their decision.

Frydman and Goldberg (2007) formulate some critical remarks towards rational expectation and efficient market hypothesis too. They are quite close to the behavioural economists’ point of view. The authors pay attention to the fact that the individuals in the foreign exchange market cope with imperfect knowledge. They stress importance of the revision of the agent forecasting strategies over time at the same time mentioning that even “social context” should be considered as important determinant of the strategy formulation process. They also describe the agents as conservative, defining this as follows: “*an individual’s forecast of the future exchange rate is not too different from the forecast she would have had if she did not revise her forecasting strategy*” (Frydman and Goldberg, 2007, p. 184).

It seems that formulating a model that would reflect true agent behavior in the foreign exchange market in a proper way is more complicated task than the supporters of traditional efficient market hypothesis would like to present. Such a model should have an evolutionary, dynamic character, show making decision processes based on *trial and error* strategy which are treated as optimisation, however, under imperfect knowledge assumption. Genetic algorithm appears to be quite suitable to imitate agents’ behavior in the foreign exchange market in the real world if we want to meet majority of these criteria.

Methodology of the research

Dynamic Model of Speculative Attack

Both models by Obstfeld (1986) and by Morris and Shin (1998) have some shortcomings and in this paper these models are extended (especially Morris and Shin’s one) and made more applicable. Neither “multiple equilibria” approach nor “uniqueness” take into account time as important factor, they are both static. Therefore, in our paper dynamics of the model is introduced. We follow some elements of the model proposed by Angeletos, Hellwig and Pavan (2006). Their model offers rather general framework

how to apply dynamic global games into a regime change mechanism. It can be applied for modeling speculation against a currency peg (which is of our priority interest), at the same time the model can be also used for some other purposes like explaining run against a bank or some other (not strictly economic) processes, for example a revolution against a dictator. There are two important features of the model. Firstly, it allows the agents to learn, therefore, the multiplicity is connected with information dynamics. And secondly, the fundamentals matter for the regime outcome prediction, although not for timing and number of attacks. However, the model presents only one side perspective, i.e. the speculator one, and the payoff function of Central Bank is not analysed. Moreover, we are not quite sure if it is fully satisfying to accept:

“summarizing the private information by the agent about at any given period in a one dimensional sufficient statistic, and capturing the dynamics of the cross-sectional distribution of the static in a parsimonious way” (Angeletos, Hellwig and Pavan, 2006, p. 1-2),

and then to apply this algorithm to examine the effects of learning on equilibria in the model. Instead, we offer well defined genetic algorithm to simulate learning process, and as we think that the Central Bank can also learn, in fact the genetic algorithm is used to show how decisions of two categories of agents are changing as far as their knowledge on the proportion of attacking speculators is concerned.

In our model time is discrete and indexed by $t \in \{1, 2, \dots\}$. Agents are indexed by $n \in \{1, \dots, N_t, N_t + 1\}$, where agents $1, \dots, N_t$ are speculators and agent $N_t + 1$ is the Central Bank. Subscript t is used, since we assume that number of speculators considering attack evaluates in time. Therefore there is a sequence $\{N_t\}_{t \in \{1, 2, \dots\}}$, which is not observed. The Central Bank receives ex post information about the number of speculators attacking denoted by α . We assume that each speculator considering attack, attacks with the same probability, therefore we have relationship:

$$\alpha_t = N_t \kappa_t, \quad t = 1, 2, \dots \quad (1)$$

where κ_t denotes probability that a chosen speculators attacks. α is observed ex post, however N and κ are unobserved. Of course α and κ

evaluate in time too, therefore we have sequences $\{\alpha_t\}_{t \in \{1,2,\dots\}}$ and $\{\kappa_t\}_{t \in \{1,2,\dots\}} \cdot \{er_t\}_{t \in \{1,2,\dots\}}$ is a sequence of observed exchange rates and $\{\theta_t\}_{t \in \{1,2,\dots\}}$ is a sequence of the true values of fundamentals. Similarly as in the model of Morris and Shin (1998) we assume that there are only 2 possible states of exchange rate. Exchange rate is pegged at a level e^* or depends on the fundamentals and is equal to $f(\theta)$. An action set for the Central Bank is binary, which means that the Central Bank can defend the exchange-rate peg or abandon it. Since speculators can attack the exchange-rate peg or refrain from doing so, their action set is binary too. We assume that $er_1 = e^*$. The game is continued until a state $er_t = f(\theta_t)$ is reached or if after a finite number of periods dominant strategy is not to attack. According to the model of Angeletos, Hellwig, Pagan (2006) each player receives a private signal $x_t^n = \theta_t + \varepsilon_t^n$, where for $n = 1, \dots, N$

$\varepsilon_t^n \sim N\left(0, \frac{1}{\beta_t}\right)$ is noise, independent identically distributed across agents.

In the case of the Central Bank we assume that a noise $\varepsilon_t^{N_t+1} \sim N\left(0, \frac{1}{\tilde{\beta}_t}\right)$ is independent of noises $\varepsilon_t^1, \dots, \varepsilon_t^{N_t}$ and we assume that for all t the inequality $\tilde{\beta}_t > \beta_t$ is valid because knowledge of the level of fundamentals is more precise in the case of the Central Bank than in the case of speculators. It is assumed in our paper that uncertainty concerning the level of fundamentals decreases and therefore $\forall_{s>t} \beta_s > \beta_t$. Morris and Shin (1998) and Angeletos, Hellwig, Pagan (2006) assumed that the level of fundamentals was random too, however in our model we consider different nonrandom trajectories of $\{\theta_t\}_{t \in \{1,2,\dots\}}$. In our paper $c(\cdot, \cdot, \cdot, \cdot)$ denotes the Central Bank cost function. This cost depends similarly as in the paper of Morris and Shin (1998) the state of fundamentals θ . In our paper this function depends on the total number of speculators considering attack N and probability that a chosen speculator attacks κ . We assume that the total

number of speculators considering attack evaluates according to the formula:

$$N_t = N_1 + (t-1)\tau. \quad t = 1, 2, \dots \quad (2)$$

Our extension of the paper of Morris and Shin (1998) is to make cost of intervention dependent of the level of reserves r too. We assume that $c(N_1, \tau, \kappa, \theta, r)$ is a continuous function and $\frac{\partial c(N_1, \tau, \kappa, \theta, r)}{\partial N_1} > 0$, $\frac{\partial c(N_1, \tau, \kappa, \theta, r)}{\partial \tau} > 0$, $\frac{\partial c(N_1, \tau, \kappa, \theta, r)}{\partial \kappa} > 0$, $\frac{\partial c(N_1, \tau, \kappa, \theta, r)}{\partial \theta} < 0$ and $\frac{\partial c(N_1, \tau, \kappa, \theta, r)}{\partial r} < 0$. Total number of speculators in the beginning period is not known but it has to be predicted by each agent. Therefore for each n , N_1^n denotes predicted by the n -th agent total number of speculators considering attack on the foreign exchange market. Similarly τ and κ is not known and has to be predicted by all agents. τ is constant but predictions of this quantity change in time, therefore for each agent we have sequence $\{\tau_t^n\}_{t \in \{1, 2, \dots\}}$. Analogously we have a sequence $\{\kappa_t^n\}_{t \in \{1, 2, \dots\}}$. Since our model is dynamic, we define time-dependent cost function $c_t(N_1, \tau, \kappa_{t-1}, \theta_{t-1}, r_{t-1})$, $t = 2, 3, \dots$. Lagged variables are included, because action is done in period $t-1$ and results of choice are observed in period t . Comparing to the paper of Morris and Shin (1998), one of extensions is based on the fact that the cost function is specified. We choose linear specification:

$$c_t = \gamma_1(N_1 + \tau(t-2))\kappa_{t-1} + \gamma_2\theta_{t-1} + \gamma_3r_{t-1}, \quad t = 2, 3, \dots, \quad (3)$$

where $\gamma_1 > 0$, $\gamma_2 < 0$, $\gamma_3 < 0$ are nonrandom and known constants.

Similarly as in the model of Morris and Shin (1998), if the Central Bank defends the peg, it receives value v but faces a cost c .

Optimal strategies for the Central Bank and for speculators

We suppose that all agents do action in the period $t - 1$ and the result of this action is observed in period t . Let $\{ST_t^n\}_{t \in \{1,2,\dots\}}$ denotes a sequence of strategies chosen by the n -th agent. $pay_t^n(ST_{t-1}^n)$ denotes the payoff in period t for an agent number n , if this agent chooses action ST_{t-1}^n in period $t - 1$. As we mentioned above $ST_t^n \in \{0,1\}$ for all n . In the case of speculators we suppose that ST_t^n is 1 if speculator decides to attack currency and is 0 otherwise. If $ST_t^{N_t+1} = 1$, the Central Bank decides to defend the exchange-rate peg and if $ST_t^{N_t+1} = 0$, then the Central Bank abandons the exchange-rate peg. The following table shows payoffs for speculators in period t in the period $t - 1$ exchange rate is pegged at the level e^* :

Table 1. Payoffs for speculators in period t ($er_{t-1} = e^*$)

	$ST_{t-1}^{N_t+1}$	0	1
ST_{t-1}^n	0	0	0
1	$(e^* - f(\theta_t)) - tr$	$-tr$	

Source: Own calculations

Central Bank's payoff depends on the proportion of speculators attacking, state of fundamentals and the level of reserves. The payoff is defined in the following way:

$$pay_t^{N_t+1}(ST_{t-1}^{N_t+1}) = \begin{cases} 0 & \text{if } ST_{t-1}^{N_t+1} = 0, \\ v - \gamma_1(N_t + \tau(t-2))\kappa_{t-1} - \gamma_2\theta_{t-1} - \gamma_3r_{t-1} & \text{if } ST_{t-1}^{N_t+1} = 1. \end{cases} \quad (4)$$

Since neither the true proportion of speculators attacking nor state of fundamentals are known in the period of attack, expected payoff is calculated. This expected payoff is given by formula:

$$E\left[\text{pay}_t^{N_t+1} (ST_{t-1}^{N_t+1}) \right] = \begin{cases} 0 & \text{if } ST_{t-1}^{N_t+1} = 0, \\ v - \gamma_1 (N_1^{N_t+1} + \tau_{t-1}^{N_t+1} (t-2)) \kappa_{t-1}^{N_t+1} - \gamma_2 x_{t-1}^{N_t+1} - \gamma_3 r_{t-1} & \text{if } ST_{t-1}^{N_t+1} = 1. \end{cases} \quad (5)$$

Firstly we consider the border cases. We define a binary variable bad_t which is 1 if the state of fundamentals and reserves is extremely bad and even in the case of “no attack” the exchange-rate peg is abandoned and we define a binary variable $good_t$ which is 1 if the state of fundamentals and reserves is extremely good. “Extremely good state of reserves and fundamentals” means that even in the case of all speculators attacking in period t , then $E\left[\text{pay}_{t+1}^{N_{t+1}+1} (1) \right] > 0$. Value of variable bad_t is defined below:

$$bad_t = 1 \left\{ \left(x_t^{N_t+1}, r_t \right) : v - \gamma_2 x_t^{N_t+1} - \gamma_3 r_t < 0 \right\}. \quad (6)$$

Analogously variable $good_t$ is defined by the following formula:

$$good_t = 1 \left\{ \left(x_t^{N_t+1}, r_t \right) : v - \gamma_1 - \gamma_2 x_t^{N_t+1} - \gamma_3 r_t > 0 \right\}. \quad (7)$$

If a variable bad_t is 1, then a dominant strategy for the Central Bank is to abandon the exchange-rate peg. Otherwise if $good_t$ is 1, then a dominant strategy is to defend the exchange rate peg. There is no reason to attack for the speculators, if payoff from attacking (even if the attack is successful) is smaller than a transaction cost, which means that:

$$e^* - f(\theta_t) < tr. \quad (8)$$

Then a dominant strategy for speculators is to refrain from attacking.

If conditions (6) and (7) are not satisfied, then there exists such $\tilde{\kappa}_{t-1}^{N_{t-1}+1}$ that solves the following equation against $\kappa_{t-1}^{N_{t-1}+1}$:

$$v = \gamma_1 \left(N_1^{N_{t-1}+1} + \tau_{t-1}^{N_{t-1}+1} (t-2) \right) \kappa_{t-1}^{N_{t-1}+1} + \gamma_2 x_{t-1}^{N_{t-1}+1} + \gamma_3 r_{t-1}. \quad (9)$$

Then an optimal strategy for the Central Bank is defined as follows:

$$ST_{t-1}^{N_{t-1}+1} = 1 \left\{ \kappa_{t-1}^{N_{t-1}+1} < \frac{v - \gamma_2 x_{t-1}^{N_{t-1}+1} - \gamma_3 r_{t-1}}{\gamma_1 \left(N_1^{N_{t-1}+1} + \tau_{t-1}^{N_{t-1}+1} (t-2) \right)} \right\}. \quad (10)$$

Similarly as in the case of the Central Bank, critical value $\tilde{\kappa}_{t-1}^n$ is defined for each speculator. This value is calculated analogously changing an index $N_{t-1}+1$ by n for $n=1, \dots, N_{t-1}$. Speculators do not have any information on a state of fundamentals observed by the Central Bank and predicted by the Central Bank values of parameters N_1 and predicted by the Central Bank probability of attacking by a chosen speculator κ . Therefore they have to rely on their own observations and predictions to formulate the payoff function of the Central Bank. There is a reason to attack for the speculators if the predicted probability of attacking exceeds the critical value. Therefore if inequality (8) is not satisfied, then an optimal strategy for speculators is given by the following formula:

$$ST_{t-1}^n = 1 \left\{ \kappa_{t-1}^n > \frac{v - \gamma_2 x_{t-1}^n - \gamma_3 r_{t-1}}{\gamma_1 \left(N_1^n + \tau_{t-1}^n (t-2) \right)} \right\}. \quad (11)$$

As we have already mentioned, parameters of the cost function of the Central Bank are known only to the CB but unknown to the speculators.

Genetic algorithm in the process of learning

In the first period for each n predicted total number of speculator considering attack is equal to N . Similarly, predictions of τ and κ are purely random for each agent. In the second period Central Bank knows value

of $\alpha_1 = \kappa_1 N_1$. The Central Bank assumes that probability of attacking by individual speculator in a given period is the same as this probability in previous period and therefore predicts values of κ and τ in the next periods using the following recursive formula:

$$\kappa_{t+1}^{N_{t+1}+1} = \frac{\kappa_t^{N_t+1} N_t^{N_t+1}}{\alpha_t}. \quad (12)$$

Parameter τ is predicted according to the following formula:

$$\tau_{t+1}^{N_{t+1}+1} = \frac{\left(\frac{\alpha_t}{\kappa_t^{N_t+1}} - \frac{\alpha_1}{\kappa_1^{N_1+1}} \right)}{t-1}. \quad (13)$$

Since forex market is not fully transparent, we assume that speculators do not have any information concerning number of speculators attacking in the previous period. But they observe their own payoffs and if payoff for the first speculator is higher than payoff for the second one, then this first speculator has higher chance to “survive” than the second one. It is obvious that speculators with higher payoffs are satisfied with their decisions and they do not have any incentive to change the tactic. Speculators with negative payoffs decide to change their tactic. They learn tactic from the speculators with positive payoffs. New speculators enter the FX market. Dynamics on the FX market imitates nature, where only correctly fitted spiches survive. Spiches that are not able to adapt to the environment are replaced by the spiches that are better fitted. Crossover can be interpreted as a knowledge exchange. Considering all this FX market can be modeled as evolving system of the autonomous interacting agents and hence the genetic algorithm can be applied here. Analyzing formula for optimal strategy of n –th speculator in period t , we can notice that this strategy depends on parameters $\kappa_{t-1}^n, \gamma_1, \gamma_2, \gamma_3, \tau_{t-1}^n, N_1^n$. Speculators do not know these parameters and their knowledge concerning them is changing from first period to the second one. We assume that these parameters are different for different periods and different speculators. We denote γ_{it}^n as predicted value of parameter $\gamma_i, i = 1,2,3$ in period t by n –th speculator.

In order to use genetic algorithm we have to define range of possible values of parameters. It is obvious that:

$$\forall_{t \in \{2,3,\dots\}} \forall_n \kappa_{t-1}^n \in (0,1]. \quad (14)$$

We have to choose minimum and maximum values of parameters $\gamma_1, \gamma_2, \gamma_3, \tau, N_1$, after choosing these values, we have:

$$\begin{aligned} \forall_{t,n} \gamma_{1t}^n &\in \langle \gamma_1^{\min}, \gamma_1^{\max} \rangle, \forall_{t,n} \gamma_{2t}^n \in \langle \gamma_2^{\min}, \gamma_2^{\max} \rangle, \forall_{t,n} \gamma_{3t}^n \in \langle \gamma_3^{\min}, \gamma_3^{\max} \rangle, \\ \forall_{t,n} \tau_t^n &\in \langle \tau^{\min}, \tau^{\max} \rangle, \forall_{t,n} N_1^n \in \langle N_1^{\min}, N_1^{\max} \rangle. \end{aligned}$$

If we choose precision ε , then number of gens in one chromosome is equal to:

$$\begin{aligned} GENS &= \left\lceil \log_2 \frac{1}{\varepsilon} \right\rceil + \sum_{i=1}^3 \left\lceil \log_2 \frac{(\gamma_i^{\max} - \gamma_i^{\min})}{\varepsilon} \right\rceil + \log_2 \frac{(\tau^{\max} - \tau^{\min})}{\varepsilon} + \log_2 \frac{(N_1^{\max} - N_1^{\min})}{1} + \\ &+ 6 - 1 \left\{ \log_2 \frac{1}{\varepsilon} \in Z \right\} - \sum_{i=1}^3 1 \left\{ \log_2 \frac{(\gamma_i^{\max} - \gamma_i^{\min})}{\varepsilon} \in Z \right\} - 1 \left\{ \log_2 \frac{(\tau^{\max} - \tau^{\min})}{1} \in Z \right\} + \\ &\quad (15) \\ &- 1 \left\{ \log_2 \frac{(N_1^{\max} - N_1^{\min})}{1} \in Z \right\}, \end{aligned}$$

where $[x]$ denotes integer value of x . First $\left\lceil \log_2 \frac{1}{\varepsilon} \right\rceil + 1 - 1 \left\{ \log_2 \frac{1}{\varepsilon} \in Z \right\}$ gens represent strategy concerning the expected probability of attacking by a chosen speculator, next $\left\lceil \log_2 \frac{(\gamma_1^{\max} - \gamma_1^{\min})}{\varepsilon} \right\rceil + 1 - 1 \left\{ \log_2 \frac{(\gamma_1^{\max} - \gamma_1^{\min})}{\varepsilon} \in Z \right\}$ gens represent strategy concerning the value of parameter γ_1 etc. In order to introduce crossover and mutation we define quantities $pc(\kappa), pc(\gamma_1), pc(\gamma_2), pc(\gamma_3), pc(\tau), pc(N_1)$, which denote probabilities of crossover for gens of two chromosomes for a given parameter.

$pm(\kappa), pm(\gamma_1), pm(\gamma_2), pm(\gamma_3), pm(\tau), pm(N_1)$ denote probability of mutation of respective gens and $pr(\kappa), pr(\gamma_1), pr(\gamma_2), pr(\gamma_3), pr(\tau), pr(N_1)$ denote proportion of gens in appropriate part of chromosome, which are crossed over. Before we calculate fitness function, for simplicity we define the following variables:

$$\begin{aligned}
 SS_t^n &= 1 \left\{ e^* - f(\theta_t + \varepsilon_t^n) - tr > 0 \right\}, \quad n=1, \dots, N_t, \quad t=1, 2, \dots, \\
 SB_t &= 1 \left\{ v - \gamma_1 \kappa_t (N_1^{N_t+1} + \tau_t^{N_t+1} (t-1)) - \gamma_2 (\theta_t + \varepsilon_t^{N_t+1}) - \gamma_3 r_t > 0 \right\}, \\
 &\quad t=1, 2, \dots, \quad (16) \\
 SBS_t^n &= 1 \left\{ v - \gamma_1^n \kappa_t^n (N_1^n + \tau_t^n (t-1)) - \gamma_2^n (\theta_t + \varepsilon_t^n) - \gamma_3^n r_t > 0 \right\}, \\
 n &= 1, \dots, N_t.
 \end{aligned}$$

If $SS_t^n = 1$, then attack is considered by the n -th speculator in period t . Otherwise transaction costs exceed payoff and attack is not taken into account. Value of variable SB_t informs us about the strategy of the Central Bank. Central Bank abandons the exchange-rate peg if $SB_t = 0$ and defends it otherwise. Variable SBS_t^n can be interpreted as expected (by the n -th speculator) strategy of the Central Bank. SBS_t^n is 1 if the n -th speculator predicts that the Central Bank will defend the exchange-rate peg and 0 otherwise. Since payoff may be negative, we do monotonic transformation in order to calculate the value of the fitness function:

$$F_t^n = \exp(\text{pay}_{t+1}^n). \quad (17)$$

The fitness function in our model is given by the following formula:

$$F_t^n = \begin{cases} \exp(-tr) & \text{if } SS_t^n SB_t = 1 \wedge SBS_t^n = 0, \\ \exp(0) = 1 & \text{if } SS_t^n SBS_t^n = 0, \\ \exp(e^* - f(\theta_t) - tr) & \text{if } SS_t^n SBS_t^n = 1 \wedge SB_t = 0. \end{cases} \quad (18)$$

We use roulette-wheel selection method in order to choose appropriate chromosomes in the next period.

In the first simulation experiment probability of abandoning the exchange-rate peg is calculated. If after 20 periods the Central Bank does not change its strategy and still defends exchange-rate peg or dominant strategy for speculators is not to attack, then we assume that the exchange-rate peg is abandoned. Experiment is done for different states of fundamentals (weak fundamentals, medium fundamentals, strong fundamentals), different levels of reserves (low reserves, medium reserves, high reserves) and dif-

ferent values of parameter τ . We assume that $N_1 = 10$, $N_1^{\min} = 7$, $N_1^{\max} = 13$. If $\tau = 2$, then $\tau^{\min} = 1$ and $\tau^{\max} = 3$. Else if $\tau = 5$, then $\tau^{\min} = 3$ and $\tau^{\max} = 7$. In our experiment predicted numbers of speculators in the first period are randomly selected in the following way:

$$P(N_1^n = k) = \begin{cases} \frac{1}{6} & \text{for } k = 7, \dots, 13, \\ 0 & \text{for } k \notin \{7, \dots, 13\} \end{cases} \quad \text{for } n = 1, 2, \dots, N_1 \quad (19a)$$

and

$$P(N_1^{N_1+1} = k) = \begin{cases} \frac{1}{3} & \text{for } k = 9, \dots, 11, \\ 0 & \text{for } k \notin \{9, \dots, 11\} \end{cases} . \quad (19b)$$

κ_1^n is selected randomly from $U(0,1)$ for all agents. Similarly τ^n is selected randomly for all agents in the first period. We assume that if $\tau = 2$, then

$$P(\tau_1^n = k) = \frac{1}{3}, \text{ for } k = 1, 2, 3 \text{ and } n = 1, \dots, N_1 + 1. \quad (20a)$$

If $\tau = 5$, then:

$$P(\tau_1^n = k) = \frac{1}{5}, \text{ for } k = 3, 4, 5, 6, 7 \text{ and } n = 1, \dots, N_1 \quad (20b)$$

and

$$P(\tau_1^{N_1+1} = k) = \frac{1}{3}, \text{ for } k = 4, 5, 6. \quad (20c)$$

In the case of the Central Bank, values of parameter τ in periods $t = 2, 3, \dots$ are obtained according to the formula (13) and values of parameter κ are obtained according to the formula (12). In the case of speculators, values of parameters τ and κ in periods $t = 2, 3, \dots$ result from the use of genetic algorithm. Speculators with higher payoffs have higher chances not to change their strategy. Speculators with negative payoffs have higher chances to use a different strategy in the next period. Constant parameters are as follows:

$$e^* = 2, v = 3, \quad \gamma_1 = 0,8, \quad \gamma_2 = -0,7, \quad \gamma_3 = -0,8, \quad \gamma_1^{\min} = 0, \quad \gamma_1^{\max} = 2, \\ \gamma_2^{\min} = -2, \quad \gamma_2^{\max} = 0, \quad \gamma_3^{\min} = -2, \quad \gamma_3^{\max} = 0, \quad \beta_t = 5t, \quad \tilde{\beta}_t = 10t, \\ f(\theta_t) = \theta_t, \quad tr = 0,35.$$

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

In the case of weak fundamentals, θ_t is given by the following formula:

$$\theta_t = 1,2 + 0,01t ,$$

in the case of medium fundamentals we have:

$$\theta_t = 1,4 + 0,01t ,$$

in the case of strong fundamentals θ_t is given by formula:

$$\theta_t = 1,6 + 0,01t ,$$

whereas in the case of very strong fundamentals we have:

$$\theta_t = 1,7 + 0,01t$$

In the case of low reserves, r_t is given by the following formula:

$$r_t = 1 + 0,01t ,$$

in the case of medium reserves we have:

$$r_t = 3 + 0,01t$$

and in the case of high reserves we have:

$$r_t = 5 + 0,01t .$$

τ takes on values 2 and 5.

We conducted 10 000 replications and calculated probability of abandoning the exchange-rate peg. We received the following results:

Table 2a. Probability of Defending the Exchange-Rate Peg if number of speculators increases slowly

$\tau = 2$				
Fundamentals Reserves	Weak	Medium	Strong	Very strong
Low	0,0770	0,1006	0,2807	
Medium	0,2826	0,3214	0,5763	0,8281
High	0,5479	0,5735	0,8291	0,9832

Source: Own calculations

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

Table 2b. Probability of Defending the Exchange-Rate Peg if number of speculators increases fast

$\tau = 5$				
Fundamentals Reserves	Weak	Medium	Strong	Very strong
Low	0,0063	0,0120	0,0915	0,5573
Medium	0,0437	0,0679		0,8092
High	0,1367	0,1779		0,9827

Source: Own calculations

According to the results from the tables 2a and 2b, probability of defending the exchange-rate peg increases if state of fundamentals improves. The same relation concerns level of reserves. If the Central Bank keeps high level of reserves then the probability of abandoning the exchange-rate peg is higher than in the case of medium and weak reserves. Comparing values in the table 2a to the corresponding values in the table 2b, we can notice that probability of defending the exchange-rate peg is higher when number of speculators increases slower. It means that with the intensification of globalization and financial markets liberalization process, the Central Bank has lower chances to defend the exchange-rate peg.

In the second simulation experiment mean payoff for speculators is calculated. The same parameters are used as in the first experiment and the same variants are considered. Experiment is based on 10 000 replications. The results are as follows:

Table 3a. Mean payoff for speculators if number of speculators increases slowly

$\tau = 2$				
Fundamentals Reserves	Weak	Medium	Strong	Very strong
Low	0,28	-0,96	-1,72	-0,87
Medium	-1,35	-2,25	-2,24	-0,56
High	-2,23	-2,89	-2,25	-0,46

Source: Own calculations.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

Table 3b. Mean payoff for speculators if number of speculators increases fast

$\tau = 5$				
Fundamentals Reserves	Weak	Medium	Strong	Very strong
Low	1,56	0,02	-1,58	-0,84
Medium	0,56	-1,15	-1,98	-0,78
High	-0,39	-2,31	-2,78	-0,63

Source: Own calculations.

According to the tables 3a and 3b, speculators reach positive payoffs for weak fundamentals and low reserves. For increasing level of reserves and for better fundamentals, mean payoff for speculators decreases, but this relation is non-linear. It can be seen that in the case of very strong fundamentals mean payoff for speculators is higher than in the case of strong or sometimes even medium fundamentals. This phenomenon results from the fact that if fundamentals are very strong then speculators know that probability of inefficient attack is higher. Therefore lower number of speculators decides to attack and even if they attack, they change tactic after first period of inefficient attack. Comparing values in the table 3a to the corresponding values in the table 3b, we notice that if number of speculators increases faster, then mean payoff for speculators is higher.

In the third simulation experiment average time of collapse the exchange-rate peg is calculated. Though we assume that if the exchange-rate peg survives 20 periods, game is over, we put value 20 if the exchange-rate peg is defended. The same parameters are used as in the first experiment and the same variants are considered. Experiment is based on 10 000 replications. The results are as follows:

Table 4a. Mean time of duration of the exchange rate-peg, when number of speculators increases slowly

$\tau = 2$				
Fundamentals Reserves	Weak	Medium	Strong	Very strong
Low	3,80	4,40	7,39	12,79
Medium	8,54	9,19	12,90	16,73
High	13,59	13,98	17,40	19,68

Source: Own calculations.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

Table 4b. Mean time of duration of the exchange rate-peg, when number of speculators increases fast

$\tau = 5$				
Fundamentals Reserves	Weak	Medium	Strong	Very strong
Low	2,01	2,25	4,04	7,57
Medium	3,80	4,32	9,16	16,41
High	6,60	4,59	11,32	19,67

Source: Own calculations.

Comparing results in the tables 4a and 4b, we can notice positive relation between the state of fundamentals and duration of the exchange-rate peg and positive relation between the level of reserves and duration of the exchange-rate peg. If the fundamentals are weak and the level of reserves is low, exchange-rate peg collapses very fast. If fundamentals are very strong and the level of reserves is high, then the mean duration of the exchange-rate peg is close to 20 periods, which means that in most situation exchange-rate peg is defended. This result agrees with the result from the first Monte Carlo experiment. Comparing values in the table 4a to the corresponding values in the table 4b, we can notice that average duration of the exchange-rate peg is higher in the case of slower pace of increasing of number of speculators.

Conclusions

1. The model seems to catch reality in more complex way: level of noise changes in time (decreasing), there are different states of fundamentals (with “more sensitive” upper part of the scale), number of inflowing agents can be low or high (due to different globalization phases, different capital flow phases, different uncertainty levels).
2. Dynamic nature of the model is also reflected in defining some kind of continuity of CB and agent behavior. Both sides must formulate their strategies in continuous way, and therefore simultaneously, which is a shift from a single-action approach (single nonreplicable attack, located in the short run and therefore sequential decision making process) to a longer perspective.
3. In fact, the results are in line with intuition, which may confirm that the usage of genetic algorithm was a right decision. Weaker level of fundamentals decreases probability of defending the exchange rate peg and increases pay-off for speculators. If dynamics of inflow of agents is

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

higher, then probability of defending peg is lower, pay-off for speculators is higher and mean time of peg maintenance duration is lower. The higher the level of international reserves the higher probability of peg defending, the lower pay-off for speculators and the higher duration of peg maintenance.

Keywords: *public economics; real estate economics; policy mimicking; local policy instruments; clustering*

Abstract: In the article we discuss importance of the real estate related instruments, used by local government to attract investment and stimulate local economic development. The article discusses economic literature related to public economics at local government level, with the special emphasis put on link between urban and real estate economics and development. In the empirical part of the paper we analyze results of survey conducted at a local government level in Poland (Malopolska). There are two major research objectives: (1) to identify the scope of the real estate economic instruments used by the communes as part of their development policies' strategies; (2) to examine the coexistence of certain types of instruments as part of the commune development strategies.

Introduction

Since 1990s. Polish communes have become an interesting object of economic research, but some of the valid still remain unanswered. Decentralisation of the public authority in Poland, directly linked with political

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

changes initiated after 1989, resulted in creating, in its first phase, two levels of public administration, that is the central and the local (commune) levels. Further reforms undertaken a few years later introduced additional self-government levels: districts and voivodeships. Communes, constituting the smallest areas, were acknowledged to be the basic units of the local government in Poland. They were entrusted vast competences and tasks in order to meet the local societies' needs. In the light of contemporary theoretical views on the role of public authorities in social-economic life as well as views on the local development concepts which have dynamically been developing since the 1960's, local government authorities started to be perceived as the bodies responsible for undertaking active measures in order to develop local areas. Polish literature (making use of foreign literature achievements) widely discusses the real impact of the commune bodies upon development processes, the commune bodies' activity forms as well as the efficiency of available local interventionism tools. Regardless of these results and the ongoing discussion it was felt a strong responsibility of communes authorities for the proper conduct of the local economic policy and taking efforts to stimulate the development processes.

The aim of this paper is to assess the role of the real estate related instruments used by local government, in order to attract investment and stimulate local economic development. Research interests were threefold:

- 1) to identify the scope of the real estate economic instruments used by the communes as part of their development policies' strategies;
- 2) to examine the coexistence of certain types of instruments as part of the commune development strategies;
- 3) to determine if there is spatial autocorrelation between communes entities as a result of mimicking behavior in local development policies.

Empirical part is based on the data collected from the communes located in the South of Poland, in the Malopolska voivodeship.

Previous research

One of the key issues in the economic literature on local economic policy is the role of public sector in creation of a favorable investment climate and promotion of local and regional economic development. There is, however, a debate about the real impact of local economic policies on the creating a favorable business climate. In the theory, better competitiveness in local areas may attract the private capital and as the result improve the welfare. In many empirical studies the relationship between economic devel-

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

opment policies and their effects was measured (Fisher, 1997, pp. 53-82; Domański and Jarczewski (Ed.), 2006, p. 100). Some authors are convinced of a lack or only small positive impact of economic policy on the economic growth, and even argued that the negative effects of such policy are underestimated (Rubin and Rubin, 1987, pp. 37-62; Ross 1996, pp. 354-380; Piasecki (Ed.), 2007, p. 288). Others believe that economic policy is the important factor in supporting economic development (Fox and Murray, 1990, pp. 413-427; Blume, 2006, pp. 321-333). Since Tiebout (1956) significant evidence is based on the literature on effects of fiscal instruments such as taxes, subsidies and public expenditures on economic growth and welfare (Helms, 1985, pp. 574-582; Baum, 1987, pp. 348-360; Bartik, 1992, pp. 102-110; Caplan, 2001, pp. 101-122). An important focus of research in this area is the issue of tax competition. Local governments shaping local tax rates are trying to influence the investment locations of taxpayers. This action is two-pronged - on the one hand, the local authorities determine the level of the fiscal burden, on the other hand, the generated tax revenues determine the level of public services (Głuszak M. and Marona B., p. 256). In this way, there is a competition between neighboring public entities, which is debatable whether this competition is effective (Wilson J., 1999, pp. 269-304; Caplan B., 2001, pp. 101-122). Research on the local tax policy effects is often combined with the phenomenon of tax mimicking (Revelli, , p.2002, pp. 1723-1731; Allers and Elhorst, 2005, pp. 493-513; Santolini 2008, pp. 431-451; Delgado and Mayor, 2010, pp. 149-164), which indicates spatial interaction among local governments in tax setting. Empirical studies identified the impact of local tax policy on the decisions in tax policy in the neighboring entities. In the theory there are three explanations for tax mimicking (Allers and Elhorst, 2005, pp. 493-513):

- expenditure "spillovers" or "externalities" model,
- tax competition based on Tiebout model (mentioned before),
- political agency - yardstick competition model.

On the other hand, the imitation behavior is rarely examined as regards the references to other instruments of economic development (Małkowska and Telega, 2012, pp. 175-183).

Interesting approach to research is presented by the authors studying the impact of public services on economic development. In many such studies public services are estimated as statistically significant and positive for economic development process (Luce, 1994, pp. 139-67; Dalenberg and Partridge, 1995, pp. 617-640; Papke, 1991, pp. 47-68). Fisher (1997, pp.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

53-82) comparing known results in this area notes that the “results of studies vary greatly and it can be concluded that some public services have a positive effect on some measures of economic development in some cases”. Therefore, in order to take into account the specific nature of the area and the factors determining the effectiveness of economic development policy, some researchers use the case studies instead of or in addition to the econometric analysis.

One of the areas used by public authorities in order to, among others, stimulate the process of local economic development, is the real estate economy. The notion of the "real estate economy" is, from a practical point of view, reduced to managing commune real estates. A wide approach to "real estate economy" of the local governments can be defined as conscious and purposeful actions of the authorized self-governing subjects, in accordance with the law. It encompasses making decisions and undertaking factual and legal acts related to the real estate's located within the local area and aiming at specific targets which are subject to economic development policy run by the local authorities. (Cymerman, 2009, pp. 29-46). It is, in other words, a total amount of actions undertaken by the local governments and related to real estate stock in a given commune. Public real estate economy run by local governments is increasingly frequently described in the context of instruments which those governments use. There are two interesting issues:

- the problem of tools selection by the local authorities and the co-occurrence of such instruments of the groups within the local development strategies,
- mimicking the nature of politics in neighboring communities.

It is worth mentioning that only few papers investigated the influence of the instruments from the area of real estate economics on the economic development - with the exception of tax incentives and public services related to technical infrastructure (Smith, 2009, pp. 209-234). In reverse, there are not many researches on the impact of economic development policies on the local real estate market. D'Arcy and Keogh (1998) argued that the new research on territorial competitiveness should be supplemented by the role of real property and property market. So far, however, Polish literature lacks systematic studies on the real estate economy instruments, their choice, implementation or effects.

Methodology of the research

The paper presents empirical study aimed to identify different strategies in the selection of the available tools by the local governments, to assess the coexistence of chosen tools and to verify the thesis about the occurrence of imitation effect in the policy pursued by the local authorities.

The data basis of the analysis is the results of a survey conducted in the 2009. The sample in the survey was communes' authorities of the Małopolska voivodeship. The general object of the study was to determine the relationships between local government policy on the field of real estate economics and the level of local economic development. The required information was gathered through a questionnaire sent to all the communes of the province via postal mail and e-mail. Questionnaire, due to the deliberately simplified form, allowed the measurement of the majority of the variables tested according to nominal and ordinal scale. The survey form was completed by 92 commune offices, giving slightly more than 50% response rate. The share of the various types of communes (urban, rural and urban-rural) in the research sample corresponds to the overall structure of the voivodeship. The results presented below are based on the analysis of one of more important questions raised for local self-governments in the organized survey. This question referred to utilization of the enumerated instruments of real estate economy by the local authorities within the last ten years.

The potential instruments of real estate economy listed in the survey were as follows (Table 1)

Table 1. Real estate related instruments analyzed in the study

Var	Description	Percent
X ₁	preparation of location offers for investors	72,8

Source: authors' own

Information obtained from communes showed, which of above tools were applied and which were not. The research is exploratory. We analyze the survey data using multidimensional scaling (MDS) and cluster analysis (CA).

Exploratory analysis

To examine the coexistence of instruments used by communes to promote local development we analyzed survey response patterns. In the dataset 13 dichotomous variables represented real estate economy instruments potentially used (1) or not used (0) by communes. To assess similarities in response patterns we used Jaccard Index – a measure of similarity suggested by Sneath (1957). The Jaccard Index (J) for two dichotomous (0-1) variables X and Y is given by:

$$J = \frac{a}{a + b + c}$$

where:

a is number of cases where both X and Y have a value of 1.

b is number of cases where X has a value 1, while Y has value 0.

c is number of cases where X has a value 0, while Y has value 1.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

There are other measures of similarity between dichotomous responses – for example indices proposed by Dice (1945)or Rao (1948), but according to Finch (2005) the results of cluster analysis do not depend significantly of the index used to describe dis(similarity).

Table 2. Jaccard Similarity Index for real estate economy instruments used by sample communes

	X1	X2	X3	X4	X5	X6	X7	X8	X9	X10	X11	X12	X13

When analyzing data in Table 2, it seems obvious that some real estate instruments are often used together (for example X5 and X10, $J=0,91$) whereas other are not (for example X5 and X12, $J=0,32$). In order to facilitate the interpretation of the results, proximities were analyzed further with the use of multidimensional scaling.

Multidimensional Scaling (MDS) is not a separate statistical method, but rather a group of techniques used to produce maps, that can facilitate the description of multivariate phenomena found in the data. In the research we used MDS (ALSCAL algorithm) to explore relations between real estate based instruments used to promote local development. Jaccard distance was used to show (dis)similarity of instruments. Again, we assumed that the most similar instruments are these that are used together by communes

in the sample. Results are presented on a exhibit (Figure 1). The closer the points on the map the more related the respective instruments are.

Figure 1. Derived Stimulus Configuration (Euclidean distance model)

X1- preparation of location offers for investors; X2- local authority support for an investor in the process of granting construction permit; X3 - local authority support for an investor in the process of negotiation with the owners of real estate to get land for investments; X4- preparation of land for investments by means of conversion – reclassification, combining and dividing; X5- adopting plans of spatial development which are actual and convenient for investors; X6- application of lower property tax rates than statutory rates; X7-differentiation of property tax rates due to the character of business, location of the real property and type of construction; X8- using property tax reliefs and tax exemptions in relation to the character of business or investment activity; X9- development of infrastructure in the investment area for private entities; X10 - investing into development and appropriate maintenance of local road connections; X11 - purchasing land by the commune from private owners in order to prepare and provide the land to investors; X12 - temporary provision of buildings and commune premises on a lease/rental basis to conduct business activities; X13 -application of preferential rental rates for public real property in order to conduct business activities.

Based on the results of multidimensional scaling (visualized on the Fig. 1) we differentiated several groups of instruments:

- **supply side instruments:** instruments connected to zoning, conversions, planning and land development. They create new supply (X1, X4, X5, X10, X11)
- **demand side instruments:** incentives, direct and indirect financial support for new or existing investment. They aim to attract new investors (X6, X8, X9, X13).
- **procedural instruments:** the instruments from this group are connected to guidance and procedural business support for investors willing to start new operations (X2, X3)

Two instruments were distinct from the others:

- temporary provision of buildings and commune premises on a lease/rental basis to conduct business activities (X12)
- differentiation of property tax rates due to the character of business, location of the real property and type of construction (X7)

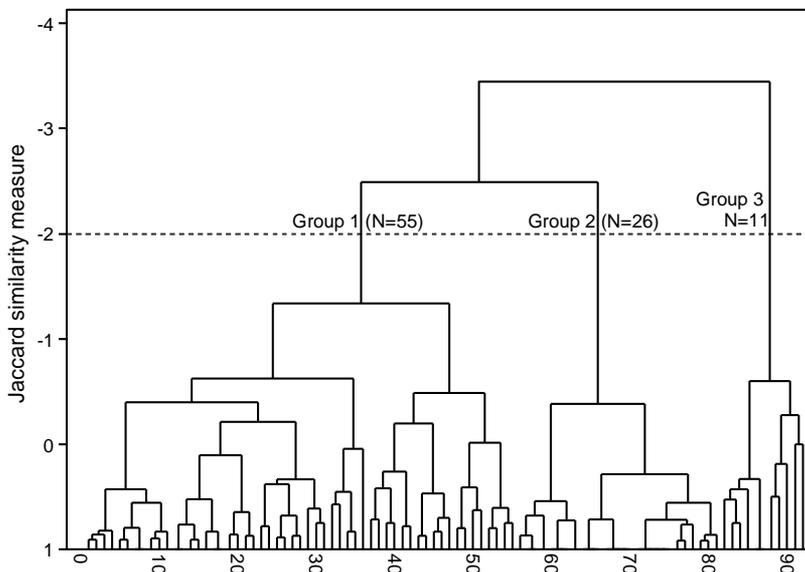

The latter two instruments are usually not used as a part of real estate strategy – they are rarely used compared with other tools. These can be referred as to occasional instruments.

Cluster analysis results

Another interesting research topic is connected to strategies used by communes while using real estate economy instruments. It is interesting to see whether there are groups of communes that use the same set of tools to promote local development. These could imply other interesting question – is there mimicking effect when it comes to applying real estate based instruments by local government. In order to find relevant answers we start from cluster analysis.

To group communes in the sample based on real estate economy instruments used in practice we used hierarchical cluster analysis. We applied Ward method of clustering described by Ward (1963), which is probably most frequently used clustering method.

Figure 2. Dendrogram for cluster analysis of sample communes based on real estate economy instruments used

Source: authors' own.

Based on the agglomeration schedule (dendrogram) we conclude that there are three basic groups of communes, clustering 55 (group1), 26 (group2, and 11 (group3) communes respectively. Descriptive statistics referring to real estate instruments usage (percentage of communes using selected instruments) were presented in the table (Table 3).

Table 3. Real estate economy instruments used by clusters of communes

Var	Group 1	Group 2	Group 3
X1	74,5%	88,5%	27,3%
X2	72,7%	88,5%	0,0%
X3	61,8%	88,5%	0,0%
X4	78,2%	96,2%	0,0%
X5	94,5%	96,2%	45,5%
X6	61,8%	96,2%	27,3%
X7	20,0%	84,6%	0,0%

Source: authors' own.

Based on the results of cluster analysis we identified three groups of communes. While communes within each group differed to some extent – it was hard to find two communes who used exactly the same set of instruments – they were relatively homogenous. The clusters were:

- Group 1 (Selective): Communes within this cluster utilized several instruments of real estate economy. On the other hand members of this cluster did not in general use property taxation incentives (lower property tax rates, differentiation of property tax rates), as well as rental tools (temporary provision of buildings for lease, or lower rental rates for public real property).
- Group 2 (Unitary): Members of this cluster were using most of real estate economics instruments. The only exemption was temporary provision of buildings and commune premises (utilized by only 38,5% communes), but this particular tool was rarely used in general.
- Group 3 (Passive): Cluster members were relatively inactive in terms of real economy instruments used to promote local development. Any of these communes declared support for investors. They did not provide infrastructure in selected areas in order to attract investors.

Last interesting question is related to geographical distribution of the clusters found. One interesting example would be nonrandom spatial distribution of the communes representing three types (groups) found in the cluster analysis. The latter case could indicate some kind of mimicking behavior. The results of the cluster analysis were plotted on the map, but the effect was inconclusive. As we only got approximately 50% response rate, there were substantial blank spots (missing observations), that make analyzing spatial distribution pattern challenging. Another problem is connected to the fact that we only have static data, and could not observe the dynamics of the mimicking process (adoption of certain tools by other communes). It is an interesting question for future research.

Conclusions

In the article we discussed the of the real estate related instruments, typically used by Polish communes to attract investment and stimulate local economic development. We analyzed results of survey conducted at a local government level in Poland (Malopolska) using multidimensional scaling and cluster analysis.

We found that direct measured like investing into local road network are the most frequently used instrument to promote local development. On the other hand, differentiation of property tax rates, and temporary provision of public buildings to investors are rarely used. In general three major categories of instruments were identified: demand, supply and procedural. Based on the array of real estate instruments used to promote local development, we grouped communes in the sample, using Ward's clustering method, into three clusters – selective (dominant), unitary and passive.

Finally, we discussed the mimicking behavior in local public policies both on theoretical and empirical level. However, we were not able to find conclusive answers on empirical bases, due to significant non-response rate in the survey in Malopolska. We conclude that more panel data research is needed, to find links between urban and real estate public policy and local government.

Semi-strong Informational Efficiency in the Polish Foreign Exchange Market

JEL Classification: *E43; E52; E58; F41; F42; C32*

Keywords: *foreign exchange market efficiency; cointegration analysis*

Abstract: During the financial crisis a notion that the Polish exchange rate is not determined effectively was very dominant, because of a contagion effect of the global financial crisis on the Polish economy. In addition, many foreign exchange market analysts explained developments in the Polish exchange market through a hypothesis that the Polish zloty exchange rate follows other exchange rates. This contradicts market efficiency as this would lead to profitable arbitrage possibility based on past information on other currency prices and possibly gives a rationale for government intervention. In contrast, a foreign exchange market that is efficient needs no government involvement and its participants cannot earn abnormal gains from foreign exchange transactions. Therefore, the aim of the article is to examine the efficiency of the Poland's foreign exchange market. In order to test for market efficiency a cointegration analysis is used. The main argument builds on the semi-strong form of the market efficiency hypothesis. On an informational effective market a pair of prices cannot be cointegrated, because this would imply predictability of one asset price based on the past prices of the other asset. The main hypothesis of the article is verified using Unit Root tests and Johansen Cointegration Test on the pair of EURPLN and USDPLN exchange rates. It is shown that the null hypothesis cannot be rejected; therefore, the Polish foreign exchange market is efficient in the semi-strong sense.

Introduction

The answers to questions regarding the form of the efficiency of the foreign exchange markets may be of fundamental importance. These markets are in fact a place where expectations on the overall economy are reflected in currency prices. These expectations, if the market is efficient, provide a valuable signal to business managers and decision-makers, stimulating them to take effective decisions. On an effective market the role of regulatory bodies is limited. In contrast, if the capital market is inefficient, their investment decisions are *ceteris paribus* more often suboptimal and this can result in significant costs for the economy as a whole. For these reasons, the conclusions drawn from the analysis of the degree of market efficiency can be important both for public authorities and financial institutions, but also for potential investors, especially international investors and market participants.

During the financial crisis the notion that the Polish exchange rate is not determined effectively was very dominant, because of a contagion effect of the global financial crisis on the Polish economy. In addition, many foreign exchange market analysts explain developments in the Polish exchange market through a hypothesis that the Polish zloty exchange follows other exchange rates. This contradicts market efficiency as this would lead to profitable arbitrage possibility based on publicly available information on other currency prices and possibly gives a rationale for government intervention.

Therefore, the aim of the article is to examine the efficiency of the Poland's foreign exchange market. The main argument builds on the semi-strong form of the market efficiency hypothesis (Fama 1970) and is based on a line of reasoning put forward by Granger (1986). On an informatively effective market a pair of prices cannot be cointegrated, because this would imply predictability of at least one asset price based on the past prices of the other asset. This contradicts the market efficiency as this would lead to profitable arbitrage possibility based on past information. The empirical analysis draws on the Johansen (1995) approach. The approach taken in the article was to test for the existence of cointegration between two pairs of daily and monthly Polish zloty foreign exchange rates. The period of observation covers the floating exchange rates of the zloty (2000-2013). It is shown that the null hypothesis can be rejected and, therefore, the Polish foreign exchange market is efficient both in the weak and semi-strong sense.

Literature review

Fama (1970) defines the informational efficiency of the financial market at three levels: weak, semi-strong, and strong forms. The investigation described herein concentrates on the semi-strong form efficiency that stipulates that the current foreign exchange rate not only reflects the historical information but also the information that is publicly available. This hypothesis assumes that foreign exchange rates adjust quickly to absorb new information. Hence, new information cannot be used by anyone for earning abnormal returns. Foreign exchange market informational efficiency can be then considered in two aspects: (i) within-currency efficiency, and (ii) cross-currency efficiency. The first aspect in the semi-strong efficiency hypotheses concerns mainly forward premium and other fundamental analyses. The second aspect of semi-strong market efficiency examines international linkages across different exchange markets in the long run. The focus of the article was put on the latter market efficiency concept.

The notion of cross-country efficiency of the foreign exchange market can be traced to the articles by MacDonald and Taylor (1989), Hakkio and Rush (1989), and Baillie and Bollerslev (1989). These authors implement the argumentation of Granger (1986) concerning stock market efficiency in the foreign exchange market in order to investigate informational efficiency. The authors' results are mixed and depend on the choice of the method - in the first two articles authors show results of the Engle-Granger procedure supporting the efficient market hypothesis, while the last two authors find support for cointegration in a sample of seven exchange rates using multivariate Johansen procedure. This was confirmed in a large study conducted by Zivot (2000) who tests the foreign exchange market efficiency for the British pound, Japanese yen, and Canadian dollar against the US dollar on a monthly basis from 1976 to 1996 and strongly rejects the efficiency hypothesis in all exchange rates.

The foreign exchange market efficiency subject was first revived upon establishing the European Monetary Union, since it was expected that currencies taking part in the monetary integration would have exhibited mean-reversal behavior towards each other on the approach to forming a common currency. Indeed, Haug, MacKinnon, and Michelis (2000), Rangvid and Sørensen (2002), and Aroskar, Sarkar, and Swanson (2004) find cointegration among the currencies of the first members of the monetary union. In particular, strong confirmation of long-run relationships between exchange

rates is present in the period before the introduction of the Euro, in which foreign exchange parities were irrevocably fixed.

The question of market efficiency has been revived for the second time during the 2007-2011 global financial crises, during which investor rationality has been questioned by many commentators. Ahmad et al. (2012) examine the within and cross-country market efficiency for 12 Asia-Pacific foreign currency markets using daily spot and one-month forward exchange rates from 1997 until 2010, and compare the 1997-98 Asian and the global financial crises. Authors conclude that foreign exchange markets are generally efficient from within-country and cross-country perspectives according to their results of Johansen cointegration tests. This study confirms the findings of Pilbeam and Olmo (2011).

Kuhl (2010) tests for cointegration in pairs of daily foreign exchange rates for periods before and after the introduction of the Euro. Only the Deutsche mark-US dollar and French franc-US dollar are cointegrated before the creation of the EMU. Like other authors, the author attributes this to the monetary integration. However, the introduction of the Euro creates two different cointegration relationships that are between Euro-US dollar and the four most important exchange rates.

The only studies in Polish foreign exchange market efficiency concern much earlier periods Grotowski and Wyroba (2006) and deal with market efficiency in the weak sense. To our knowledge there are no studies concerning the recent period of Polish zloty exchange rate instability using cointegration methods.

Methodology of the research

Consider three countries, each with a single currency following a floating exchange rate regime. This implies three exchange rates for each pair of countries. For the ease of exposition each pair of exchange rates are expressed in the same currency. The exchange rate e^{ij} can be defined as the price of the domestic currency i in terms of the foreign currency j (indirect quotation), where $i, j=1,2,3$.

It can be assumed that the expectations regarding the exchange rate $e_t^{i,j}$ in period t are based upon publicly available information set $\Phi_{t-1}^{i,j}$ that includes past realization of this exchange rate:

$$\Phi_{t-1}^{i,j} = \{e_{t-1}^{i,j}, e_{t-2}^{i,j}, e_{t-3}^{i,j}, \dots\} \quad (1)$$

This is trivial, however it is straightforward to assume that past realization of *both pairs of* exchange rates to a given domestic currency $i=1$ are known to the market participants, therefore the information set Φ_{t-1}^1 for a given currency entails both the information on historical behavior of the exchange rate $e_t^{1,2}$, that is $\Phi_{t-1}^{1,2}$, and $e_t^{1,3}$ $\Phi_{t-1}^{1,3}$. Formally:

$$\Phi_{t-1}^1 = \Phi_{t-1}^{1,2} + \Phi_{t-1}^{1,3} \quad (2)$$

If a market is informational semi-strong cross-efficient, the expectations regarding the exchange rate $e_t^{1,2}$ are formed using both information sets. It stems from this that:

$$E(e_t^{1,2} | \Phi_{t-1}^{1,2}) = E(e_t^{1,2} | \Phi_{t-1}^1) \quad (3)$$

This allows to put forward the relation of the cross exchange rates in the cointegration framework and relate it to the semi-strong form informational efficiency hypothesis in the empirical model, since the value of other exchange rates in a given currency are known to the market participants. Let us consider the Johansen procedure to test the existence of cointegration. The exposition follows Goczek, Mycielska (2014).

Assume that the two time series for the exchange rate pairs considered form a bivariate data vector \mathbf{X}_t given by:

$$\mathbf{X}_t = \begin{pmatrix} e_t^{1,2} \\ e_t^{1,3} \end{pmatrix}_t \quad (4)$$

The two variables are used to form a Vector Autoregressive (VAR) model described with the following equation:

$$\mathbf{X}_t = \Pi_0 + \Pi_1 t + \sum_{i=1}^K \Pi_i \mathbf{X}_{t-1} + \mathbf{u}_t \quad (5)$$

where the error term $\mathbf{u}_t \in N(0, \sigma^2)$ is uncorrelated over t , the data vector \mathbf{X}_t is of a dimension $p \times T$, Π_i is the deterministic coefficient matrix (intercepts or/and trends) of a dimension $p \times p + 2$. If the data are non-

stationary in levels and stationary in first differences, then the equation (2) can be rearranged to form a vector error correction mechanism:

$$\Delta \mathbf{X}_t = \Pi^* \mathbf{X}_{t-1}^* + \sum_{i=1}^{K-1} \Gamma_i \Delta \mathbf{X}_{t-i} + \mathbf{u}_t \quad (6)$$

where: $\mathbf{X}_{t-1}^* = (\mathbf{X}_{t-1}, 1, t)'$, $\Pi^* = (\Pi, \Pi_0, \Pi_1)$, $\Pi = \sum_{i=1}^K \Pi_i - I$ and $\Gamma_i = -\sum_{j=i+1}^K \Pi_j$.

The matrices Γ_i contain information on the short-run adjustment coefficients of the lagged differenced variables. Furthermore, the expression $\Pi^* \mathbf{X}_{t-1}^*$ denotes the error correction term, i.e. it includes the long-run relationships between the time series (Lutkepohl, 2005).

In general, the rank of a matrix shows the number of linearly independent processes that is equivalent to the number of linearly independent columns. According to the assumption that $\mathbf{X}_t \sim I(1)$ and $\mathbf{u}_t \sim I(0)$, both the differences of the endogenous variables and their lagged differences are stationary, thus the matrix Π is of reduced rank for the equation (6) to be balanced. If Π is of reduced rank, then there exists $p \times r$ matrices α and β such that $\Pi = \alpha\beta'$ and the equation (6) can be transformed to:

$$\Delta \mathbf{X}_t = \alpha\beta' \mathbf{X}_{t-1}^* + \sum_{i=1}^{K-1} \Gamma_i \Delta \mathbf{X}_{t-i} + \mathbf{u}_t \quad (7)$$

The term $\beta' \mathbf{X}_{t-1}^*$ with $\beta' = [1, -b]$ is the cointegrating vector showing the steady state relationship between the exchange rates. In the context of exchange rates those are linear combinations, which themselves are non-stationary, but the relationship between them is stationary with a steady state cointegrating vector. In this case, the system shown in equation (7) becomes a vector error correction model and the matrix α describes the adjustment speed for each variable after it deviates from the long-run relationship. If the matrix Π is of rank one, this means that a single cointegrating vector exists, and β' is $1 \times p + 2$ (deterministic components of the cointegrating relationship). If the rank is in fact one, this means that there exists a single cointegration vector - a single steady state relationship. In the article, three types of methods for determining the number of cointegrating

equations. The first is Johansen's "trace" statistic method. The second is his "maximum eigenvalue" statistic method. The third method chooses rank to minimize an information criterion (Akaike or Schwarz-Bayes, although Schwarz-Bayes is probably the more frequent one as it prevents the over-parametrization to greater extent – as for example in Witkowski, 2014).

This implies that the estimated error correction term ($e_{t-1}^{1,2} - b \cdot e_{t-1}^{1,3}$) becomes significant in determining the exchange rate behavior. Using the error correction term, one exchange rate can be predicted by using the other if the long run relationship and past exchange rates are known to the market. This means that causality between the exchange rates runs at least in one direction and past information on the one exchange rate can be used to profitably predict the other. It stems from this, that providing there is cointegration between the exchange rates, the market is not efficient in the weak form.

Unfortunately, a more detailed investigation of the choice of deterministic components of the potential cointegrating equation is only provided by only a few of the authors reviewed in the previous part article. The same critique applies to the number of lags used in the model. The approach taken in this article after Aznar and Salvador (2002) is to develop an unrestricted Vector Autoregressive (VAR) model in order to determine the optimal number of lags using information criteria. As in the lag-length selection problem, choosing the specification of the cointegration equation that minimizes either the Schwarz Information Criterion (SIC) or the Akaike information criterion (AIC) provides a consistent estimator of the steady-state equilibrium. Of the two criteria SIC was the preferred measure, however, changing into AIC did not change the results.

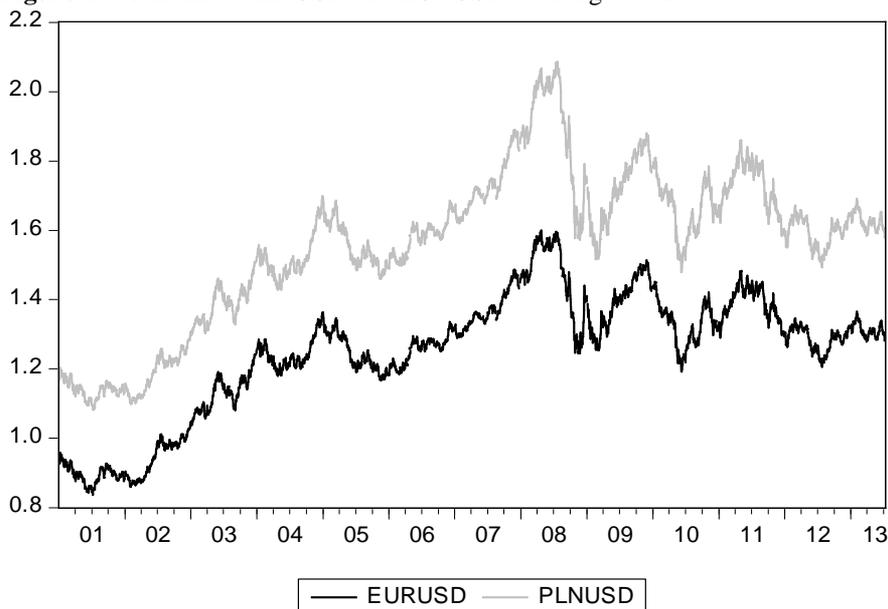

Empirical results follow in the next chapter.

Empirical model results

In the empirical investigation the EURUSD and the PLNUSD exchange rates with daily and monthly frequency are used during the period starting from April the 1st 2000 to April the 1st 2013. The start date relates to the de facto floatation of the Polish zloty. Figure 1 plots the two variables using a standard normalization procedure. It can be seen from a basic visual inspection of the two series that the stochastic processes generating this data seem to exhibit individual trends ie. the stochastic process guiding the series are not stationary. This is verified by the summary results of unit root tests. Furthermore, a visual inspection of two series makes it possible that

the two rates share a common trend. In the case of variables which are integrated of the same order it is possible to investigate the presence of a long-run relationship, which relates to the macroeconomic concept of a steady-state dynamic equilibrium between the two series. This can be determined in the data using tests for the existence of a cointegrating vector for the exchange rates.

Figure 1. Normalized PLNUSD and EURUSD exchange rates

Source: Own calculations.

The empirical analysis started with Granger Causality testing to confirm with casual the relations visible in the data. Based on the results, presented in Table 1, it was concluded that there exists a casual relationship between the two variables of interest. Based on these preliminary results it can be hypothesized that EURUSD and PLNUSD exhibit a positive feedback relationship while the USDEUR exchange rate is not influenced by PLNEUR. USDEUR is an exogenous variable that impacts PLNEUR in the Granger sense. These empirical relations point toward the notion expressed at the beginning of the article that many foreign exchange market analysts explained developments in the Polish exchange market trough a hypothesis that the Polish zloty exchange rate follows other exchange rates. In this sense, the results are quite straightforward to interpret. While this gives the motivation to devel-

18-19 June 2015, Economics and Finance**

op market efficiency verification argumentation further, it is not in any way a rejection of the efficiency hypothesis, as argued by Ferre and Hall (2010). The authors present a line of argument that if the economy is composed of N exchange rates and the closed system is analyzed without dynamics, as it is the case when considering the no-arbitrage condition, the Granger causality does not inform about efficiency.

Table 1. Pairwise Granger Causality Tests (10 Lags)

Null Hypothesis:	Obs	F-Statistic	P-value
EURUSD does not Granger Cause PLNUSD	3402	22.44138	0.0071
PLNUSD does not Granger Cause EURUSD		9.54662	8.E-16
PLNEUR does not Granger Cause USDEUR	3291	1.31777	0.2145
USDEUR does not Granger Cause PLNEUR		2.07564	0.0232

Source: Own calculations.

As a second step, Unit Roots tests were run. These tests are frequently used in the informational efficiency literature as an indication of market efficiency in the weak form. In this form of efficiency the information set includes all past prices and foreign exchange rates fully and instantly reflect all available historical information. Consequently, a market is said to be weak-form efficient if past exchange rates are useless in predicting future exchange rate. In this sense the prices are to follow a random walk and stochastic processes guiding the series should be non-stationary in levels and stationary in first differences as discussed in Goczek and Kania-Morales (2015).

The tests results for the time series exchange rate in levels and differences are shown in Table 2. The first tests were described previously generalized version of the ADF test of Elliott, Rothenberg and Stock's (1996). The test results for the time series rate in levels and differences are shown in Table 1. Both the number of levels and the number of first differences in applying the Schwert criterion determined to select a maximum number of 29 lags. This is also the number of lags was preferred by the information criteria Ng and Perron sequential t statistic in the case of data in levels. For a number of different data it was also suggested selecting the test criteria of 17 lags. In both cases, the results gave no grounds for rejecting the hypothesis of the existence of a unit root in levels and the null was rejected for first differences. On this basis, it can be assumed that the stochastic process generating exchange rates of the Polish zloty is an $I(1)$ process.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

To confirm the degree of integration of the data guiding process, the exchange rates were also tested using Kwiatowski-Phillips-Schmidt-Shin (KPSS, 1992) stationarity test. The bandwidth of the KPSS was selected according to the Schwert criteria and Bartlett kernel was used to estimate the variance term. Based on the KPSS test results shown in middle rows of Table 2 it can be stated that the stochastic processes of exchange rates are non-stationary, but the results are not as strong as in the previous tests case. Determining the order of integration of the process guiding EURPLN is quite cumbersome due to the size of the test statistics, which is not clear on the stationarity of the level series used for all standard levels of significance. In particular, the obtained test statistic is between 1% and 5% critical values, and thus depending on the accepted level of significance the stochastic process is either an I(0), or I (1).

This result was investigated further. It could be that structural breaks in the data are responsible for this result. Therefore inference on the existence of unit root using test by Zivot Andrews with a structural break in the level plus breaks in both the level and trend followed. Zivot-Andrews (1992) test confirms that the stochastic processes guiding both EURPLN and USDPLN are integrated of order one. This suggests that the Polish zloty exchange rate follows a random walk with structural breaks in both intercept and trends, and thus the Polish foreign exchange market is weak-form efficient and past prices are useless in predicting future prices, i.e., technical analysis is of no use for Forex investors.

The analysis of the data generating process went further on to analyze a simple VAR model. The reason for this analysis was to determine the number of lags necessary to perform an effective Johansen Cointegration test using information criteria. The lag length selection was based on the SIC to penalize large over identified models. Under this criterion lag length of two was selected. Changing into the AIC changed the number of lags to 19 without any impact on the obtained results. Based on this two versions of the Johansen Cointegration Test were run (the trace rank test and the maximum eigenvalue test) in order to determine the rank of the matrix Π for each possible specification of the cointegration equation. The results were summarized in Table 3 listing the number of cointegrating relations by all possible deterministic component models. The results show no significant cointegration in any of the specifications at 0.05 level, though no p-value was lower than 0.2. The lower part of table 3 contains the AIC and BIC information criteria guiding the choice of the deterministic components of the cointegrating relation, as discussed in the methodology section. Again the information criteria show point toward no cointegration in the bivariate

vector of exchange rates, however, the model with no intercept in VAR, but with an intercept in cointegrating equation was chosen.

Table 4 lists the results of both Johansen Cointegration tests with the chosen model specification. No steady state cointegrating relationship was found with a very large statistical significance. This precludes any possible errors coming from the "noise" from daily frequency of observations. Similar tests were run for monthly data obtaining the same results. This confirms the main hypothesis of the article - there is no relation between Polish zloty exchange rates and the Poland's foreign market is informatively efficient in the semi-strong sense.

The obtained results have been checked for robustness. As already mentioned both daily and monthly data were analyzed to account for the noise generated in daily data. Moreover, different pairings of exchange rates with zloty were used, however, with no change in the results (as expected due to arbitrage possibility). In addition, the sample was cut into smaller subsamples to account for the possibility of contagion in of the global financial crisis to the Polish market. The crisis interval was set from beginning of 2008 to 2010 and the whole analysis was re-run to verify the any possible contagion effect that would show through market inefficiency. Again, there are no grounds to believe that the semi-strong efficiency of the Polish zloty is violated.

The analysis was carried out also with other crisis time-spans with no difference in results. For all tested sub-periods market efficiency cannot be rejected. It seems that the Polish zloty market continues to be semi-strongly efficient even in times of crisis - a trait characteristic of the most liquid currencies in the world.

Conclusions

In this article, the Polish zloty foreign exchange market is tested for cointegration in pairs of daily foreign exchange rates for periods before and after the financial crisis in order to test semi-strong informational market efficiency. The main hypothesis of the article has been confirmed. It is shown that the null hypothesis of no cointegration cannot be rejected. As a result, it can be argued that the financial crisis has not resulted in a cross-sectionally inefficient foreign exchange market for the Polish zloty, because the cointegration relationships were not found in any of the investigated crisis sub-periods.

Confirmation of the weak and semi-strong efficiency of the market is a prerequisite for an average investment profitability based on analyzes that measure the intrinsic value of the assets of the designation (such as broadly defined fundamental analysis based on other exchange rates) and those based solely on the analysis of graphs and historical data on asset prices (broadly defined technical analysis) alike and from the point of investors these instruments are of no use. In this sense, however, there is no rationale for government intervention in the market as it allows taking optimal investment decisions. However, only a subset of the whole spectrum of tests on the effectiveness of information in foreign exchange market has been carried out and this still remains open for future research.

**Assessing the Non-financial
Investment Profitability with
Variable Discount Rate***

JEL Classification: *G11; G31; G32*

Keywords: *the cost of equity capital; risk premium; CAPM*

Abstract: In the work, the subject of the discount rate assessment is presented. It is crucial as regards assessing the non-financial investment profitability. The discount rate is usually considered as constant one in the whole investment period, which seems to be the main problem. The constant discount rate does not take into account the actual money loses value in time. Moreover, the discount rate elements can change in time and it should be remembered that many factors, which also could change, influence the value of those elements. In the work, the results of conducted research are presented and they confirm that the assumption of using the constant discount rate is erroneous. The possibility of using different techniques of risk premium valuation is also mentioned. The research allows to select the risk premium valuation to assess the non-financial investment profitability which has been characterized as long-term one.

* I would like to thank the Polish Ministry of Science and Higher Education for bailout the research presented in the work.

Introduction

The main aim of the work is to present that the use of constant discount rate at assessing non-financial investment profitability is incorrect. To fulfill the goal, the empirical research was conducted on the basis of construction area. Such research allowed to take a stance on such a formulated aim. The discount rate evaluation is one of the core elements of assessing the non-financial profitability. The incorrect discount rate value or mismatched assumption, connected with its constancy through the whole period of investment realization, can lead to incorrect assessment of non-financial investment value. The acceptance of unprofitable investment or rejection the profitable one can be the effect of such an activity. For an investor, it is crucial to realize profitable investments which can give extra profits in the future. It should be remembered that the aim of each company is the maximization of its value and it is possible because of investing. So correct investment assessment is really important.

The research methodology

The aim of the research was to show the inconsistency with assumptions of assessment methods of the non-financial investment profitability, regarding the use of constant discount rate. The research has concerned ten years' period of time and has included the period before and after the economic crisis (2004 – 2013). The analysis was realized with an example of construction area¹. The companies target screening concerned the defined period when the enterprise was traded in Polish stock exchange. The theoretical interpretation of the discount rate at assessing the non-financial investment profitability is presented in the first part of the work. Then, the methods of equity capital cost are discussed. The last part presents the measurements of conducted analysis which was used to assess the cost of capital, especially the own one. This part of the work mainly focused on determining the risk premium.

¹ According to the WIG-BUDOW enterprises condition in August 2014.

The discount rate used in the evaluation of non-financial investment profitability

The decisions referring to the non-financial investments concern the expending determined sum at present, in exchange for the income flow in the determined, future years. The process which allows to bring future cash flows into one comparable period is called discounting. The discount rate itself is a measure of used interest which should be gained to pay the credit interest or equalize the interest on alternative deposit, which was disclaimed in order to invest cash, as well as defray equity risk premium (Michalak, 2007 p.88). The discount rate at assessing non-financial investment profitability is usually set as constant one in the whole period of investment realization. The discount rate takes time preferences as well as the opportunity costs into account. It presents the possible profits from capital, invested in alternative investments. So, the whole discount rate value does not reflect the appropriate money loses value in time. The discount rate, used i.a. to assess the non-financial investment profitability, is also a part of capital cost.

As Szczepankowski shows (2007, p.85) the cost of capital can be defined in several ways (compare Hucik-Gaicka, 2007; Dulinić, 2001; Blanke-Ławniczak et. al., 2007):

- It is a value of expected return rate from alternative ventures in assets. It has got identical investment risk.
- It is a price that should be paid by an enterprise for the right to administer every single coin from the received capital.
- It is a hurdle rate of return that should be generated by a company to maintain its value.
- This is both the minimum and risk-considering return rate, that should be gained from possessed assets, and realized investments to have the presents ventures accepted by owners.
- This is the minimum profitability represented by interest. By this profitability, the investors can plough their equity capital into enterprise to get the expected profits.

The definition of capital cost was also taken up by Byrk-Kita (2007, p.89-90) who, besides the definitions presented by Szczepankowski (2007), additionally emphasized that the cost of capital is e.g.:

- The cost of enterprise financing
- The price of engaging funds

- The expenses borne by a company as a result of managing capital, in relation to its market value
- The discount rate used to discounting company cash flows which would have generate if it had not been funded with debt.

In the literature, the most common definition of equity capital cost is to determine it as desired return rate from invested capital by investors (Duliniec, 2011; Blanke-Ławniczak et.al., 2007; Pęksyk et al., 2010). The way of setting the discount rate is conditioned upon the structure of invested capital which can come from own or foreign sources as well as both the own and the foreign ones. The cost of each funding source is related to assessing both equity and debt capital cost.

The cost of equity capital

The most known methods to assess the cost of equity capital are:

- build-up method – which consist in determining risk-free rate and adding different, predetermined risk premiums (risk premium, value premium, sector-risk premium, specific-risk premium, peculiar-risk premium),
- Dividend Discount Model (DDM) – which consists in assumption that the shares value is determined by the flow of futurely pay dividends,
- Capital Assets Pricing Models (CAPM) – connected with the modern portfolio theory where the main investors aim is to maximize the return rate in relation to borne risk,
- Arbitrage Pricing Theory (APT) – based on almost one price and an arbitrage, this is the co-efficient model.

The process of determining equity capital rate, that reflects its cost, can be a problem. The difficulties can be caused not only by choosing the appropriate technique. More important is that the attention should be paid to methods imperfection. This defect can cause incorrect level of assessed equity capital cost. Above all, limitations and assumptions are the whole methods group fault. The problem concerns not only their amount but also nonverification in reality. The build-up method is proved only with smaller, nontraded enterprises. The majority of the method elements lie in subjective value calculation, which are not empirically proved. Many assumptions are out of touch with reality. For example, using the Gordon growth model (DDM), it is hard to predict and expect the constant dividend growth for longer period of time. It should be added that Gordon growth model can be used for mature enterprises with stabilized policy of dividends pay. On the

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

other hand, no-one can agree with optimistic assumptions of CAPM method concerning the lack of transaction costs (the lack of extra fees) and no limits in relation to incurring and granting loans with risk-free rate. It could cause over-liability which would reflect the lack of solvency and thereby, the possibility of bankruptcy. The point at issue is i.a. the assumption that all investors have an aversion for risk. The only one investor's attitude cannot be a limitation because it should be remembered that an investor can also be neutral or take a risk.

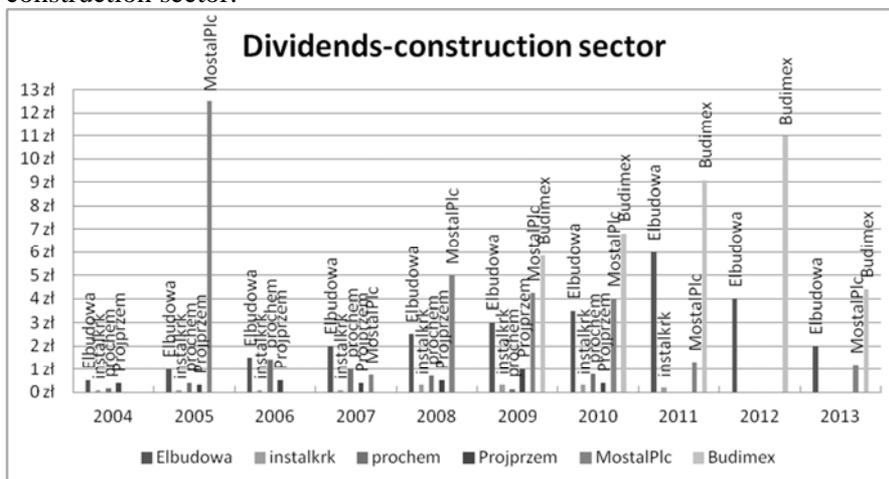

The mostly used method to assess the rate of equity capital cost is CAPM model. It was the subject matter for a lot of research but it is not critique-free. Some of the researchers called into question the linear relationship between expected return rate and systematic risk - beta (Fama, 1996). Other factors which explain return rates configuration are determined e.g. business value effect, Price Earnings Ratio, price-to-book ratio (Banz, 1981; Basu, 1977; Chan & Yasushi 1991). Some research appealed in favour of CAPM model (Black, et al., 1972; Fama & MacBeth, 1973). In the literature, besides the CAPM model critique, there are methodological problems connected with particular elements. In this case, the way of setting the risk premium is generally remarked. The difficulty in assessing the Equity Risk Premium (ERP) concerns not only the selection of appropriate data or the calculation period, but also the way of its determining. In the face of the wide range of problems, the assessment of Equity Risk Premium has been a curious issue to examine.

**The research analysis – the chosen model to assess the rate
of equity capital cost and assumptions**

The research subject to analyze the assessment of equity capital cost was the Capital Assets Pricing Model. On the other hand, the build-up method is used for nontraded company and it was counted out of using the method to assess the rate of equity capital cost. Meanwhile in the Dividend Discount Model the assumption of constant dividend growth rate is presumed. The lack of stability, in the policy of paying out dividends for construction sector, is confirmed by the analysis of enterprises reports. From among thirteen companies in the analyzed period, only one of them pay out the dividend every year, whereas the half companies pay out the dividend from five to ten years' time (diagram No. 1). Other companies did not pay out any dividends or did it once or at least three times. That is why the Div-

idend Discount Model cannot be used to assess the rate of equity capital cost for the analyzed sector.

Diagram 1. The dividends paid out for the period of five to ten years' in the construction sector.

Source: Own study on the basis of financial reports

The Arbitrage Pricing Theory was not considered because it needs the same assumptions as the CAPM model.

The Capital Assets Pricing Model is based on Sharpe, Lintner and Mossin's works (cf. Sharpe, 1964; Lintner, 1965, 1965a; Mossin, 1966) but the best known model formula was created on the basis of Fama proposal (1968):

$$E(R) = R_f + \beta^2(R_m - R_f)$$

In the conducted research, the risk-free return rate of an asset (R_f) equals the profitability of 52-week³ country treasury bills. In the literature, the way of asset choice, that represents the return rate of free-risk asset, is discussed. On one hand, the return rate of long-term securities, guaranteed by

² Enterprise systematic risk

³According to the Ministry of Finance, <http://www.finance.mf.gov.pl/dlug-publiczny/bony-i-obligacje-hurtowe/baza-transakcji>, 52-week country treasury bills were issued till 28th of March 2012. Then, the bills with the nearest period of time, in relation to the previously analyzed ones, were chosen.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

the country (debentures), is mentioned. On the other hand, the researchers indicate that the risk-free return rate is the return rate value of short-term treasury bill. The advantage of long-term assets is better time horizon match for long-term investments taking by an enterprise. The flaw is the sensitivity of interest rate future fluctuations. The investors are certain of purchasing power as well as reinvestment rate which will be available for their reinvestment of interest payment, gained from the debentures. However, short-term treasury bills are more influenced by short-term fluctuations than the debentures. But there are the treasury bills which both risk of issuer insolvency and risk of interest rate changing equal almost zero. So, the treasury bills can be described as the purest base risk-free return rate because they actually have not got the risk of interest rate uncertainty. The treasury bills contains the compensation of inflation uncertainty. However, debentures are free of insolvency risk but they are not “risk-free”. (Pratt & Grabowski, 2008 p.92).

Equity risk premium and capital cost – the research results

Equity risk premium is reflected by the difference between return rate and risk-free rate. The return rate, which is measured by the appropriate stock market index, is gained from the whole capital market (in Poland it is Warsaw Stock Exchange Index – WIG). The main aim of the conducted research was to set a premium, which was calculated in several ways:

- The difference between the market asset represented by WIG return rate, according to the beginning of the year (in accordance to the methodology of calculation the WIG annual return rate by Warsaw Stock Exchange - GWP), and the return rate from a risk-free asset at the given day.
- The difference between the daily WIG return rate and the return rate from a risk-free asset at the given day.
- The difference between average value of the WIG return rate in the year and the return rate from a risk-free asset at the given day.
- The average premium from 10 years’ time which is the average from the differences between WIG return rate, in accordance to the beginning of the year, and the return rate from a risk-free asset⁴ at the given day (it is

⁴ The average is calculated within the limits of the given year because 1) it comes out of the short history of Warsaw Stock Exchange (GWP), which is still not well developed, 2) in the past, there was another system of quotations, the Warset system, and it was implemented

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

called the average from Premium (1)). It should be added that the analysis, which treasure bills profitability was calculated on daily interest rate, was excluded because the goal of the research was to gain value “at” the given day, not “for” one given day.⁵

The risk premium can be assessed as an arithmetic or geometric mean of the differences between return rates, which are considered to assess a premium. The arithmetic mean is a historical mean of assessments of the differences between rates – it is the simplest solution and also the most popular among analysts and matches the designated Premium (4). The Premium designation in arithmetical way is correct when annual return rates are not correlated⁶, otherwise the better idea is to use the geometric mean but the weight for a geometric mean should increase including the impending of the period in hand (Prusak, 2009; Hucik-Gaicka, 2007). Using geometric mean is conditioned by positive values of the analyzed variables, it was not achieved when we consider WIG return rate. That is why, the arithmetic mean was taken into consideration in the work. That mean is also coherent with the method of determining the beta co-efficient (Szczepankowski, 2007). What is more, the weak⁷ correlation between examined return rates is in favour of using arithmetic mean.

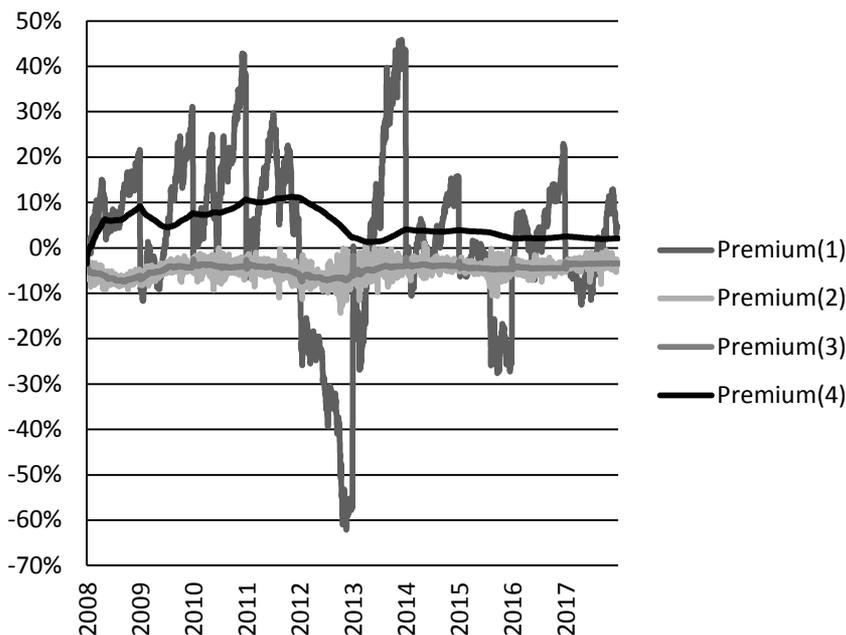

in 2003, 3) running into the past can remarkably deform the results, considering the short history of GWP.

⁵ Moreover, the incoherence between calculation interest rate should be noticed – to calculate the annual interest rate, when we have got m -number of capitalizations during the year, the formula for the effective annual interest rate should be used. The rate bases on involution. On the other hand – to get the daily rate from the annual one, the rate should be divided by the number of days in a year, which is not the opposite of involution and what our intuition can suggest.

⁶ The correlations co-efficient for annual return rates equaled -0,36. The arithmetic mean was used to calculate the premium (4) which was calculated for the given day between 2004 and 2013 – the correlation co-efficient (according to the daily data) was -0,28. Both values should be found as weak correlation.

⁷ According to the widely published interpretation of Guilford’s relationships correlation power.

Diagram 2. Risk premium assessed in four ways

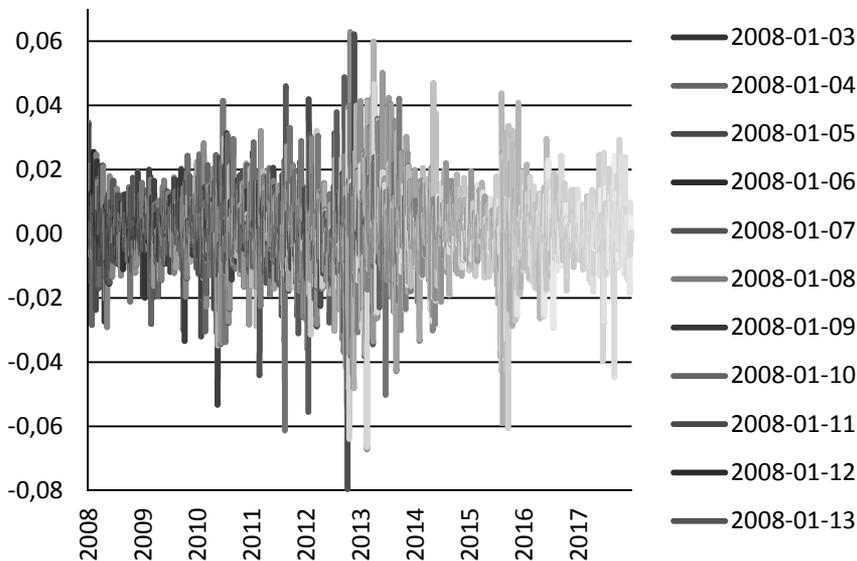

Source: Own study on the basis of market data

GWP has got comparatively short history of working. The characteristic issue is that after periods of hossas, a lot of besa periods can be expected. That is why, the premium determination, as a difference between average market return rate and fisk-free rate, was not considered in the analysis. The average return rate from the whole market would be the average of very high positive return rates and very low ones. In the diagram No 2, the results of the analysis of assessing market premium with the established methods were presented. The Premium (2) and the Premium (3) are characterized by negative values. They are caused by extremely low WIG values, which referred to daily changes. In the analyzed period, WIG-2 value (which is R_m) was changing in the range of $\langle -7,95\%; 6,27\% \rangle$, which is shown in the Diagram No. 3. However, the treasury bills value was always positive and in the range of $\langle 3,47\%; 7,51\% \rangle$, which caused the low premiums, assessed with those methods.

18-19 June 2015, Economics and Finance**

Diagram 3. WIG value – daily changes

Source: Own study on the basis of market data.

Much better way to assess is considering the WIG changes in accordance to the beginning of the year, which is coherent to the methodology of annual WIG⁸ value calculation, according to GWP.

Premium (1) reflects the capital market behaviour. Considering the premium, the period of crisis can be noticed, which strongly left an imprint on the premium value. So, it should be considered that Premium (1) is the best variant to imitate the situation in the market. Notwithstanding, considering non-financial investment, which are characterized by long time of realization, the best assessment of risk premium is Premium (4). The last of analyzed possibilities of determining the premium “flattens” the temporary return rates fluctuations and this is the premium for the given period – the long-term one. Moreover, the values premium assessed in that way are best suitable for long-term investments. It is proven by research

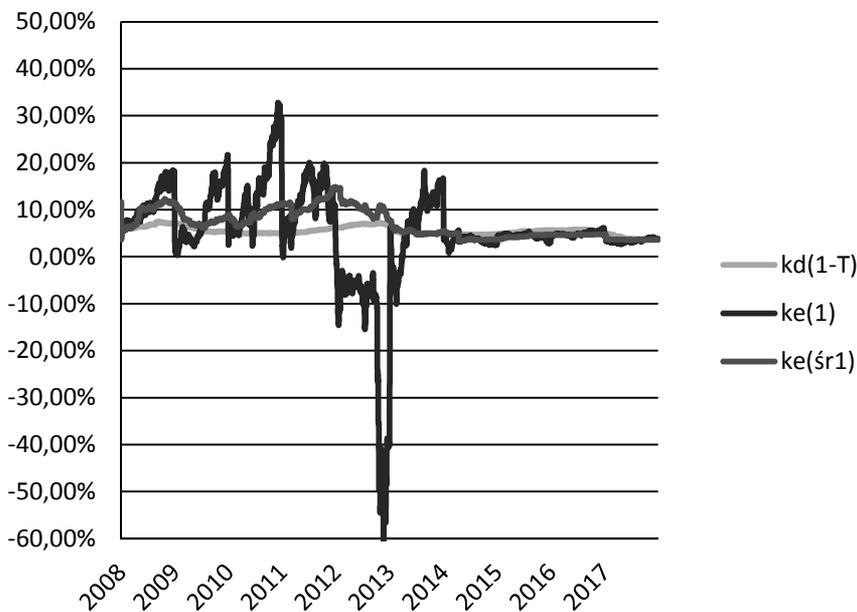

⁸ According to GWP, the value of WIG return rate for the given year is calculated as a difference between a closing bell from the last day of the year in relation to a closing bell from the last day of the previous year. The closing bell from the last day of the year equals an opening bell from the first day of a year – that is why, the concept “according to the beginning of the year” is used.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

conducted by numbers of analyzers. Those values determine the premium value, up to a few percent for longer periods. What is more, the risk premium, determined with this method for several-years period, is consistent with using arithmetic mean.

Determination and selection of risk premium allow to assess the rate of equity capital cost. Next, the cost of debt capital was determined. It caused the determining of WACC rate for analyzed companies. The results are going to be discussed for all⁹ examined companies, however the diagrams are going to be presented only for 3 previously selected companies – Diagrams No. 4, 5, 6.

Because the assessed values of risk premium concern WIG return rates and treasury bills, the risk premium does not change for each company. Within the limits, the differences in capital cost are related to beta coefficient¹³, which is the reflection of systematic risk of the given company. So, the systematic risk has the biggest influence on the value of equity capital cost in CAPM model. However, the same tendency of changing the rate of equity capital cost is determined by assessed risk premium. Additionally, it should be noticed that, in the years of economic crisis, the cost of equity capital ($k_e(1)$) for all companies was negative, which results from the calculations. It confirms in the belief that the best assessing method of risk premium, for the needs of non-financial investments, is Premium(4). That premium is related to the characteristic feature of non-financial investment which is long-term. The negative cost of equity capital would not reflect in the interpretation of equity capital cost, which is the demanding return rate from the invested capital. The negative value would mean negatively about the invested capital of the enterprise. It should be noticed that the equity capital cost at the given day can differ remarkably.

The analyzes of capital cost was enriched by the determining debt capital cost (calculated on the basis of the rate of Warsaw Interbank Offered Rate (WIBOR)3m and 2% margin), reduced by tax shield. It allowed to determine WACC for each company. The results of assessing the discount rate with WACC method are presented in the diagram No. 7 and diagram No. 8.

¹³ Co-efficient beta was measured as co-variance of investment returns, together with the return in the portfolio market. To save the comparison of co-variances for particular investments, the comparison of co-variance is divided by the returns from the whole market.

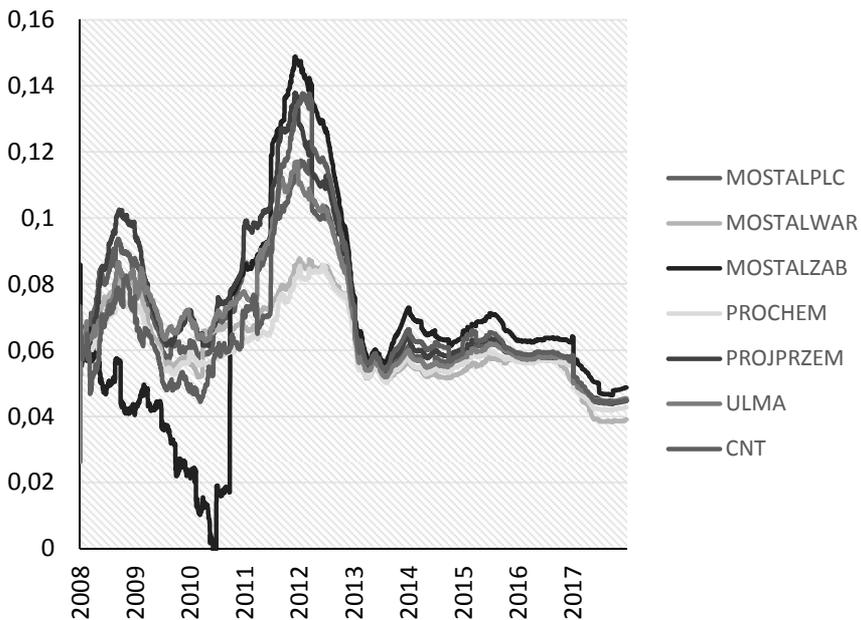

**Proceedings of the 8th International Conference on Applied Economics

Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

The results present that sometimes, the debt capital cost can be higher than the equity capital cost (it depends on the situation in the market) which happens very often during the years of crisis. The assumed methods of calculation the risk premium allow to take such situations into consideration. Among conducted research for 13 companies, it was the most significant for: Elkop (diagram No. 4), MostalPlc, MostalWar, CNT, Prochem (diagram No. 6). Nevertheless, the most important conclusion is the assumption that the capital cost rate (calculated with WACC), which is the discount rate, is not constant in the analyzed period – Diagram No. 7 and Diagram No. 8. Over the ten years, the capital cost measured with WACC (assumptions: $k_c(\text{sr}1)$ for equity capital cost because it is the best match to the long-term investment character) was changing. Over the course of time, the difference minimized (using average premium “flattened” the values), however the value of capital cost was changing with time.

Conclusions

The conducted research allows to calculate equity capital cost considering several different possibilities of assessing risk premium. The value of risk premium can differ remarkably, not only considering the choice of the premium assessing methods. The value differs every day. The conducted research allows to select the market premium assessing method. Premium(1) exemplifies the situation in the market well, which is short-term as well. In the case of decision-making, concerning non-financial investments, which are long-term, the best solution is premium(4). Premium(4) is the average value of premium(1) for the given period. The average value is better for long-term period because, when assessing the discount rate for the needs of non-financial investments, the investor should consider long-wave market information.

In the analyzed period, it was presented that the capital cost of examined companies, calculated on any given day in the examined period, changes. The conducted research allowed to show that the discount rate (determined by WACC) varies in time and the constant discount rate should not be determined during the assessment of non-financial investment profitability for the whole period of investment realization. The variable discount rate can cause that so far considered investment will be unprofitable, however if constant discount rate was used, the investment would be profitable.

Comparison of Public, Non-Profit and Private Hospitals

JEL Classification: *I110; I120; I130; P36*

Keywords: *analysis; comparison; health care; hospitals; soft budget constraint syndrome (SBC)*

Abstract: The health care system in Germany is undergoing a phase of transformation. The resulting challenges and fields of action for the hospitals were described as one outcome of a scenario analysis conducted by the author. These include, for example, setting up new organisation structures, professionalising management competence or also developing a comprehensive quality management system. In the following analysis, the hospitals are to be described and compared to one another in terms of their initial conditions regarding these fields of action. The question at the focus is which different prerequisites and options the clinics have subject to their organisational structure.

Introduction and Research Questions

The hospital sector in Germany is in undergoing a phase of transformation. The reasons are, amongst others, increasing costs, also furthered by enormous scientific advances in medical and pharmaceutical research and insufficient income, also due to the changing age structure in Germany. In addition, there are the inefficient healthcare structures, which, compared with other structures in the service provider market, remain below its po-

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

tentialities. All this causes a paradigm shift of inpatient hospital care organisation in Germany.

The article builds on the already available research results of the author. Using the methodology of scenario analysis, the author has analysed the present situation of the German healthcare systems and from this has derived a trend scenario. This trend scenario describes the progressive development of regionalised, commercially oriented healthcare structures rather as a result than as a directed process, caused by the economic crisis of the public healthcare sector. According to this, not one of the fragmented participants in the healthcare system is today in a position to bring the potentials of medical top-level research, training and medical technology to the regions, to the customer, with integrated health services. The changes to the determining factors for hospitals, such as the increasing shortage of funds, the demographic change as well as the developments in medical technology and the reform course in the healthcare sector, such as the introduction of Diagnosis Related Group (DRG) payments, the repeal of the sector border between outpatient and inpatient care and the introduction of quality management and quality assurance demand consequences from the clinic operators. These include creating new organisation forms to secure financial survival, professionalising management competence, establishing a stringent management of the business processes, developing comprehensive quality management systems, adapting the portfolio to suit customer needs, professionalising the service and reflect their hospital with ethical corporate principles.

Based on this, it is to be investigated in the following, which determining factors the hospitals bring to the table, based on their formal structure, in order to rise to the challenges described in the trend scenario. Specifically the following research questions will be dealt with:

- Which initial conditions and options for action can be derived for the hospitals in the context of their formal structure?
- How does the management of the hospitals react to the options for action in the context of their formal structure?

The analysis theoretically draws upon the findings of Luhmann (1971, 1984) that system structures and/or their formal structures act as decision-making premises to take social action and can be used for organisational analyses. In this connection system structures are the operative programs as conditional or as purpose programs, the organisation structure as the form of coordination and communication, here in the extreme characteristic between hierarchy and market and thirdly the staff (type) and its (value) cul-

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

ture. The thesis that is derived from this is that the hospitals have different possibilities for solutions and approaches to solutions to rise to the described challenges depending on their organisational structure.

In order to develop a better understanding of this thesis, public, non-profit and private hospitals will hereafter be analysed in terms of their specific features such as program, objective target, organisation, management and leadership and governance. These specific features are to be compared to one another in the context of the challenges, fields of action and possibilities for solutions to achieve effective hospital management for the benefit of the patient.

Research Methodology

The qualitative research method in the form of qualitative, guideline-based interviews was selected as the research design.

Table 1. Hospitals participating in the evaluation, status 2012

Facility/ operator	Approval	Beds	Employees	Patients (inpatients) /cases per year
University clinic-Corporation of public law//Federal state	Maximum care	3200 beds/ 100 clinics grouped in 17 centres	13.000	Approx. 136,000
Municipal hospital as state-run enterprise /Local authority	Acute care hospital with specialised medical services	960 beds/ 15 clinics and special wards/ 3 centres	1800	Approx. 35,000
Denominational hospital as an association/ Social welfare association	Acute care hospital with basic medical services	240 beds/ 5 special wards/ 3 centres (certified)	600	Approx. 12,000
Hospital as GmbH [private limited company]/ District/Local authority	Acute care hospital with basic medical services/ specialised medical services and other hospital psychiatric care	4 hospitals/ totalling approx. 1000 beds	1900	Approx. 32,000
Helios-Klinikum*	Acute care hospital with basic medical services and specialised medical care	570 beds/ 15 clinics	1000	Approx. 24,000

*The HELIOS Kliniken Group is made up of 74 own clinics, including 51 acute care hospitals and 20 rehabilitation clinics and medical care centres, status as in December 2013. HELIOS provides services in all areas of patient care, from the outpatient and inpatient acute medical care to rehabilitation and geriatric care.

Source: own research.

Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

This means that clinics of all organisation types and legal forms are included in the study. In terms of approval status, the hospitals range from maximum care to basic care. All clinics are federated in networks. Although this selection does not permit a representative statement, it does nevertheless document the trend of the respective operator and the management in the hospital. This is a conscious approach.

Alongside the case study, the analyses from the studies, an extensive literature research and also a databank research were incorporated.

Seven interviews were conducted according to the interview guideline. This method makes it possible to determine subjective views of those involved, e.g. on past events, opinions or experience, which in turn make enhanced insights possible (Bortz & Döring, 1995, p. 283). The following persons were interviewed:

- Head of the Division Corporate Development (university clinic, public hospital)
- Commercial Director (non-profit hospital)
- Managing Director (private hospital (P KKH))
- Medical Director (non-profit hospital, public hospital)
- Nursing Service Management (non-profit hospital, private hospital)
- Quality Manager (non-profit hospital, public hospital)
- Ward Doctor (non-profit hospital, private hospital).

The following central questions were developed.

Table 2. Guideline for conducting interviews in the hospitals

Corporate policy, intent and purpose of your hospital
Where do you see the main intent and purpose of your hospital (basic purpose)? Humanity and treatment according to the will of the patient? Fulfilment of social and humanitarian duty? The term "production" is often referred to in hospitals, where do you stand on this? The hospital as a service provider for the needs of the people? How would you describe the basic objectives of your hospital? Have you formulated principles of conduct when dealing with stakeholder groups (e.g. social objective targets)? Have you developed a basic concept for management?
Societal and social context
What would you say to the following influencing factors: Demographic development and impact on costs Scientific and technical advance as cost driver Regional network-building Standards that are specified by health care policy and state administration
Citizen / patient
How would you describe a patient /citizen? Responsible, self-determined, active and confident, well informed - or? Who would you consider to be your customer: Health insurance or patient? Patient or citizen?

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

<p>The patient as an economic production factor? What does concern for the patient mean to you? Pastoral care as an offer -"Advertising" or mission?</p>
Employees
<p>Burnout/ sickness of employees, what is the picture in your hospital? How do you motivate the employees? What do you ask for / expect from the employees? Are your employees all regular members of staff or do you also sometimes have temporary workers in care and treatment? How do you integrate the doctors in private practices who also attend to patients in your hospital into your team? There is often talk of "Senior Consultants having their own kingdom..." etc. "Doctors are the gods in white", what is your view? As an employer what "performances" do you offer your employees?</p>
Structure and process
<p>How is your view on the proposition?: Working in an environment accustomed to hierarchy impedes inter-disciplinary OE processes? How does the flow of information function in your hospital? What reports are prepared and how are they communicated? Which communication tools and structures are used? Could you describe typical procedures and the tools used? Process organisation, SOP (Standard Operating Procedure) what do you think, is the present organisational structure in your hospital appropriate? Structures impact the culture, the values and the practices. Please describe each of these in your division in two to three statements.</p>
Economy/ quality as area of tension
<p>What is your view on: Conduct and relationships of organisation members: thinking and acting in the interest of the organisation (intrapreneurs) or thinking and acting in their own interest? What has priority? Economy or quality? How are these measured at first? What is your view on: Conduct and relationship of doctors to care/ patient? Competent, responsible, exploitation of power gap?</p>
Strategy (Strategic Management)
<p>Can you state your strategy in a few words?</p>
<p>Who is the funding body and do you know its strategy and how are you as the hospital involved in implementing the strategy?</p>
<p>Could you please describe how the strategic planning process works in your hospital?</p>
<p>How do you measure the success of the planning targets?</p>
<p>What are the most important key figures, indicators with which you measure the success of your hospital?</p>
<p>How was the mission statement developed? Who was involved in the process? How is the mission statement communicated?</p>
<p>In one sentence, describe how you see your hospital 10 years from now?</p>
<p>Are you familiar with the macroenvironmental analysis tool PEST or the Five Forces model? Do you use these tools?</p>
<p>Specialisation, standardisation, segmentation, comprehensive care, integrated care, patient-centred care, what comes to mind when you hear these terms?</p>
<p>What do you think of network structures, how would you describe your present situation and which related developments could you imagine?</p>
<p>Who are your most important stakeholders? How do you involve them in your business?</p>
<p>What is your opinion on key figure systems, such as e.g. the Balanced Scorecard?</p>

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

Are you using a similar system?
How often and with whom do you meet for so-called strategy meetings? What is the outcome of such meetings? How do you develop your strategy further?
What is more important in your view: Placing the patients at the focus or the basic economic conditions for the hospital?
Please briefly describe the cooperation with the doctors in private practice. Who is the Owner of the patient data?
How often do you follow the situation in your "rival hospitals"? Do you look at e.g. market share, patient numbers, case numbers, etc.? And do you follow the development of your "rival's" portfolio?
Are you judged by the attainment of the strategic objective targets?
Do you judge the responsible officers of the subordinate hierarchies by the strategic target attainment?
Who bears the responsibility for what in your hospital?
As how functional and success promoting would you characterise and assess your management organisation (perhaps three-person board)?
If you were to summarise the trend in the healthcare system, how would you describe it?
Which IT is used in your hospital?
What are the most important challenges for the immediate future that you must tackle as hospital management and what areas for action do you see here?
Strategic planning: Do you have a 5-year plan? Do you have a budget on a multi-annual basis? Please describe the planning process.
Operative management
What are your most important targets in this year?
What kind of cost accounting do you perform? Do you already calculate using the hospital fee system InEK [Institut zur Entwicklung des Entgeltsystems im Krankenhaus]? Do you already use activity-based costing? Do you have a breakeven analysis? Could you please describe it briefly?
Please describe the annual planning process. Do you set cost targets in the budget? Based on what? Do you negotiate these with the specialist clinics? On which level is the budget employed? Do you have a business plan?
Does accounting controlling take place in your hospital? How is the medical documentation performed? How would you judge the quality here? Key word: revenue controlling how does that work in your hospital? What are the most important operative key figures that you use to manage the hospital? On which function level are these key figures employed?
Do you have a Quality Manager? What tasks and functions does he fulfil? Do you have a process handbook? What is the status of the conversion to standardised treatment paths?
How do you measure the utilisation of your infrastructure? (Equipment / operating theatres / beds etc.)
Which role does controlling play and where is it located? Do you perform target-performance comparisons / deviation analyses / proposals for action / assumption monitoring?
Reducing the length of stay: How do you control this?
Do you measure patient and also employee satisfaction?
Management and leadership
Do you work with target agreements? Up to which level are these employed?

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

Do you check these target achievements and if so, how?
Incentive system: what means do you employ?
Is there any (planned) staff development? How do you plan this?
If you were to describe the basic leadership style in your hospital, how would you characterise it?
How is your target achievement judged and by whom? Who determines your targets, do you have personal goals or goals that involve the whole hospital?
How do you manage the problem that you must exert economic pressure onto the medical staff? How do they deal with this?
What is your view on: Management based on figures and key figures versus management that influences behaviour

Source: own research.

Proceeding from the idea that "telling stories" is a better way to record subjective perceptions, emotions and feelings than in a controlled interview, the following 10 interviewees participated in a narrative interview:

- Head of Division Corporate Development (public hospital)
- Commercial Director (non-profit hospital)
- Managing Director hospital association (public hospital)
- Managing Director (private hospital, public hospital)
- Quality Manager (non-profit hospital, public hospital)
- Head of Human resources (public hospital)
- Controller (public hospital, non-profit hospital)
- Doctors (public hospital, non-profit hospital, private hospital)
- Nursing staff (public hospital, non-profit hospital, private hospital)
- Specialist nurse (public hospital, non-profit hospital, private hospital)

Various questions from the guideline interview were used to encourage the interviewees to talk and tell. The group discussion is closely related to the method of questioning and can be seen as a "specific form of group interview" (Lammek, 1995, p.125); in other words as a talk under "laboratory conditions", in which several people provide information on a topic that a discussion leader defines. In this case the talks were rather of an "investigative" nature that means the focus during the discussion was on the information than content results. By using this method the author was primarily interested in recording the opinions and attitudes of the individual participants of a group, and checking whether these deviate from the group opinion (e.g. when investigating the goals of the individuals participants, the researching of the values and maxim for acting of the individuals as well as of the group as a whole) in addition to analysing how the problem solving functions in the group (e.g. in the board meeting as well as in the coffee break in the non-profit and in the public hospital).

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

Observation in the narrower sense is understood as the collecting of experience (data) in a non-communicative process using all possibilities of perception. In contrast to day-to-day observation, the scientific observation is more focused, method-controlled and inter-subjective. It typically uses tools that guarantee the self-reflection, systematics and traceability of the observation and help extend the limits of our own ability to perceive. Using observation, quantitative and also qualitative data can be produced; the latter then form the interpretative access to the observed events (Bortz & Döring, 1995, p. 240).

The aim of the scientific observation here was mainly the direct observation of human actions, linguistic statements, non-verbal reactions (facial expression, gestures, body language) and social characteristics (clothing, symbols, habits, etc.) The focus was on recording the course and the significance of individual actions and action patterns as well as the relationship structure. No other form of data collection permits the researcher to gain such a deep insight into the day-to-day events in a social community, the manifold moral concepts and interests of the participants and their social context. All those observed were informed in advance of the scope, execution, date and content of the observation. Amongst the tools used was a certification process in the hospital over two days on which all hierarchy levels including nurses and doctors of the hospital were represented. This method was used in a non-profit hospital.

Further, the qualitative analysis was evaluated according to the following structure:

Table 3. Structure of analysis

Profiles of the hospitals according to corporate policy, intent and purpose/patients/ employees		
Strategies	Structure	Systems
Entire hospital (funding)	Processes: Normative orientation process Strategic decision-making process Operative management process Management business process Supportive processes	Management system (including Controlling)

The aim is to present the strategic and operative management of the hospitals and the hospital management in the actual situation of the, in order to make conclusive statements whether and how the different operator and so the formal structure affect the management and how the individual clinic operators react to these challenges.

Results

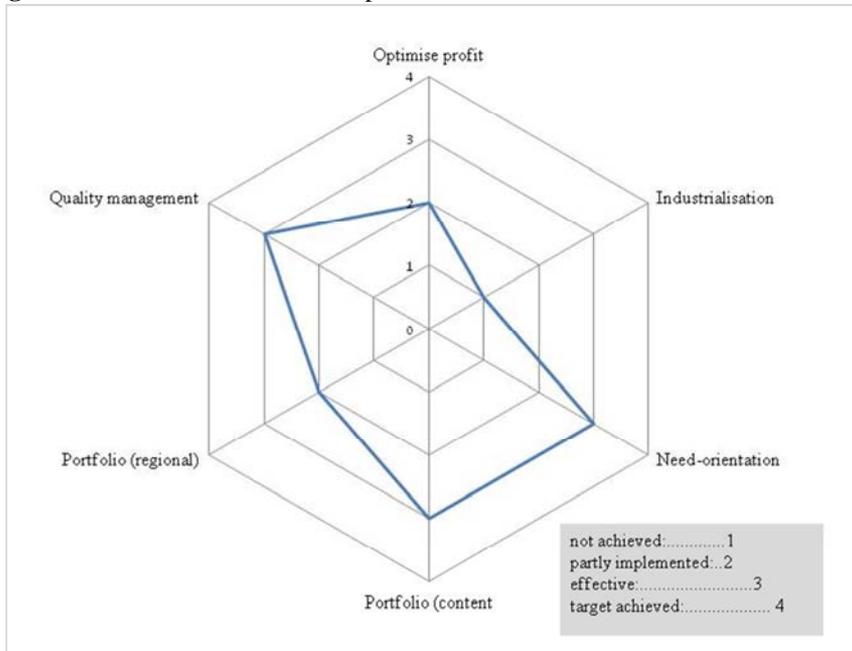

This article refrains from presenting the actual situation in detail and rather refers to the publication by Held (2014, pp. 53-105). This paper focuses on the comparison of the hospitals in the context of meeting these challenges. The challenges are derived from the scenario analysis (Held, 2012, pp.99-250) and outline the following:

- securing the operative profitability and long-term existence of the hospital, ensuring the required investment (result optimisation and use)
- integrated provision of services, personalised for the patient, industrialised in the service preparation (industrialisation and realisation of personalised medical care)
- management of the own service offerings (portfolio) oriented according to the customer needs (need orientation)
- organisation of the need-oriented and end-to end provision of services along the value chain (adaptable integration of the own portfolio into a complete overall portfolio)(content portfolio integration)
- integration of the own portfolio in the regional context (the right service in the right place)(regional portfolio integration),
- ensuring a high quality level of service (Quality Management).

In a hexagonal shape the individual hospitals are now divided into public hospital as a state-run institution, non-profit hospital and private hospital, and compared regarding their potentials to meet the challenges. The potentials were derived as conclusions from the actual-analysis.

Public hospital

Figure 3. Action areas and their implementation

Source: own research.

Typical for the public hospital are:

- no sustainable corporate profit targets
- very good quality in the required services provided (particularly university clinics)
- regional (according to politically defined regions) competition amongst hospitals (regarding patients, funding, retention of workplaces)
- No potential (finances) to shape transformation, scientific and technical possibilities or strategic restructuring.
- As an individual hospital no possibility to realise inter-disciplinary, personalised medical care, innovation and clinical studies (exception: university clinic).

The public hospitals are very good regarding the provision of services (quality). However, operative measures and the daily business, one-sided cost-saving activities (such as e.g. restructuring, outsourcing, lean management) are merely an effort to optimise the status quo. Measures to in-

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

crease profitability develop substantial growth potentials by following a new strategic direction, are still missing in most public hospitals (approx. 50% of all hospitals in Germany generate losses in 2012 (www.dki.de; Krankenhausbarometer 2012)).

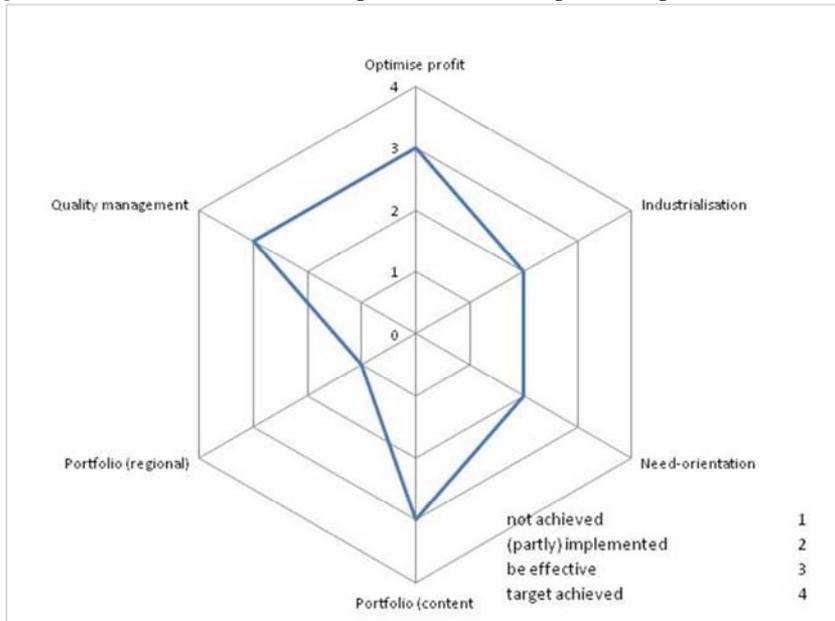

Municipal hospitals are limited in their development due to the regionalising tendencies. The politically determined constituencies thus represent a management inconsistency in themselves. The financing of the restructuring can only work if sufficient funds are available, these must be earned. This means: Standardisation and industrialisation are the necessary requirements to improve the result orientation whilst maintaining stable demands on quality. Personalised medical care, standardisation and industrialisation in order to utilise the economies of scale mean being cross-regional and acting in networks and associations.

From a historic perspective, the service offerings of the public hospitals are well established. The fulfilment of the public service mission with a state-prescribed bed plan was and still is the main focus of hospital management. However, every public hospital acts independently, these basic conditions are now cumbersome under the partly introduced competitive conditions. Hospitals that have united to form networks, only do so in the politically determined region, to form maximum purchasing groups. Maintaining and securing workplaces is here often the primary objective. Within the region (municipality, district) instead of joining forces, the hospitals compete with one another and also with private service providers, so that they can offer their core services optimised regarding profits at a high quality level.

It is necessary that the hospitals are integrated into the holistic, patient-oriented healthcare service, within a healthcare region, that is determined by the state (in cooperation with the health insurance) according to the number of insured, accessibility and other service levels.

Non-profit hospital

Figure 4. Action areas and their implementation-non-profit hospitals

Source: own research

Typical for the non-profit hospital are:

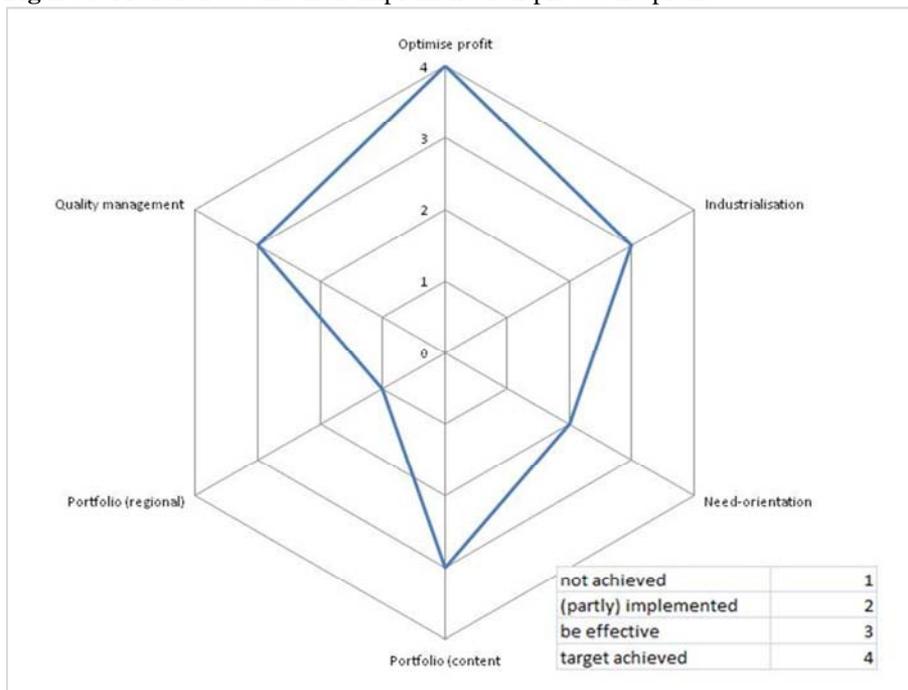

- implementation potential for new strategic orientation among private hospitals
- regional limits regarding operator and funding
- very high quality in provision of services, with additional pastoral care and benefits
- introversive needs orientation.

The content management in the non-profit hospital is primarily geared to profit optimisation, in order to generate revenue for investments with which the need orientation is then pursued. Also here the operator (funding) is the limiting factor. The operators are likewise organised regionally. This means that the same conditions exist as with the public hospitals as a societal conflict of objectives. In contrast to the public hospitals, the profit orientation plays a greater role. As a result, networks are already being established that include a holistic healthcare service package of prevention, to diagnosis, therapy to care and rehabilitation, but also training and child

care, in order to utilise the economies of scale. However, these networks or associations also do not appear as healthcare providers in a healthcare region, that means that they too do not focus on the care requirements of a region, but rather compete with other clinics for patients, for newer healthcare services etc. and are not integrated in the holistic, necessary portfolio of the healthcare region with the healthcare services they offer.

Private hospital

Figure 5. Action areas and their implementation-private hospitals

Source: own research

- The private hospital is
- optimised within itself
- has sufficient potential for transformation and reorganisation due to the good profit situation
- very high quality of healthcare service.

As a rule it generates sufficient margins to make necessary investments and as a private provider with a good profit situation various possibilities to

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

obtain the required funds (loans, leasing) on the financial market. However, here too the needs orientation is rather introversive, the portfolio management is geared to market and revenue aspects and is not orientated to the needs of the healthcare region. Results are measured and deviations are handled in quality management. This is necessary to be able to keep an eye on the quality level whilst optimising profits.

The private clinics also have the potential (financial) but they do not act sustainably in the sense of the healthcare region but rather follow the profits; however, there is not yet a respective (controlled) region described and operated by a regional management.

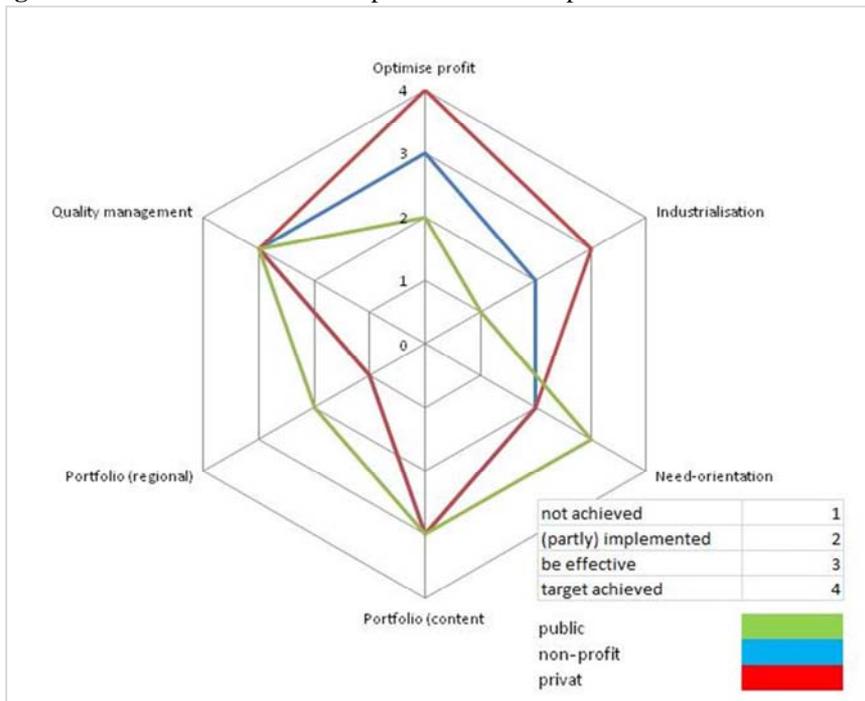

The clinic or the network, the limited company, the holding, the public limited company optimises itself "within itself" since it functions as a corporation. In contrast to the public hospitals, the clinics must prove their liquidity, since otherwise there is the threat of insolvency, operate profitably, since they otherwise use up expenditure without replacement, generate revenue in order to invest, plan and manage strategically, in order to safeguard the long-term existence of the hospital. This has a direct effect on the operative management, the operative targets and the shaping of the relationship between principal and agent. The managing director in the private clinic as the agent will only be able to hold his position if the targets of the principal are also achieved. This creates the pressure, which leads to target-oriented management.

Discussion of the results - formulating recommendations for action

The results of all three types of hospital are superimposed and shown in the hexagon.

It is clear to see that both the private hospitals and also the no-profit hospitals are better equipped to manage the necessary transformation process in the healthcare sector regarding their (also) economic orientation than the public hospitals. The way ahead leads to standardisation and industrialisation in order to utilise economies of scale and scope and release related learning curve effects. These principles do not need to be "introduced" but are rather shaped in the market.

Figure 6. Action areas and their implementation-compare

Source: own research

The operators of the public and non-profit hospitals provide the framework, the premise and so also set the limit for the required reorganisation. It is not the management team on site that determines a respective premise of action in the hospitals, but rather the general conditions, which in turn are determined by the respective type of operator. The management in the establishments thus depends on the respective culture and the target objectives of the operator. And this is not the necessity to be profitable, since until now there was no need to manage shortages as long as financial funds can be topped up at any time, no cost awareness, no transparency and no sustainable economic and also social (for society as a whole) action. This can be subsumed under the term: Soft Budget Constraint Syndrome (Kornai, 2009).

Kornai (2009) has analysed this phenomenon by using the example of the health care system in Hungary and he labelled it the „soft budget constraint (SBC) syndrome“ versus “hard budgets”. He states: „The appearance of a SBC in the hospital sector is not peculiar to Hungary, or the post-

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

socialist region. It is propensity that necessarily appears in all regions including modern, democratically governed capitalism, where state ownership, state regulations, and state financing have a necessarily great role to play. Furthermore, it reproduces itself, retreating but resurging after a time.” (Kornai, 2009, p. 133)

The effects of this system guideline can be described as follows:

- The enterprises develop somewhat of a “begging mentality”. They know that they have the support from the state (Held, 2014, p.75). The economy as the mayor force gets suspended (principle of scarcity).
- Soft Limitations for budget distort competition. Because of the fact that the state secures the maintenance, enterprises can act comfortable. Innovation, optimization and product development are no longer decisive for their survival (Held, 2014, p. 91).
- The support of permanently deficit enterprises cost vast sums.
- Because of a missing commitment of the enterprises, there are also profitless investments that are realised (D-M-Modell) (Dewatripont/ Maskin 1995).

All effects described by Kornai, can also be unveiled for the German health care system. Through interviews with experts and the scientific observation the same defects were detected (Held, 2014, pp.130-143). Soft Limitations for budget which lead to a suspension of the economy in the public hospitals are the fourth determinant. Results are deficiencies in the health care system that leads to entropy of the system. The term “deficiencies“ does not mean there is a lack of something generally, rather it is a term we find in logistics (Jünemann, 1989, p.18). There is not the correct amount of goods or services available at the right time, at the right place and in the adequate quality. Therefore, deficiencies in the health care mean an under -coverage of the actual need of goods, deficiencies in services and economic resources, a gap in supplies of goods and services, a gap in supplies of material and equipment, deficiencies in productivity (Held, 2014, pp. 70).

The significance of an under -coverage of goods and services becomes evident if one looks at the waiting time in hospitals (<http://www.dkgev.de/dkg.php/cat/62/title/Statistik>), or if one takes into account that integrated, personalized supply is only available in a central-location-system. Further, there is only a more and more fragmentary supply offered in rural areas, which is not enough to offer all citizens the best possible supply with optimal prices. A planning of locations for hospitals in line with accessibility of primary care simply is not satisfactory. It is not

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

possible to evaluate if 10 or 20 minutes to access the next hospital for the primary care is good or bad, because a benchmark is missing. It would be more needful to provide a service catalogue and guarantee its contents (e.g.: n-days to get to the next specialist, n hours to get to the emergency doctor, n minutes to get in touch with the next doctor for example via an emergency hotline, n minutes resource-availability) which however is not possible within the given structures.

A further significance of a deficiency is that the optimal production factor is not encouraged, e.g. input of material and manpower but rather one uses what is in place. This can be observed in hospitals. Deficiencies stimulates hoarding. Deficiencies cause an excess effort of operative administration and mislead to a neglect of perspective questions towards economic development.

Deficiencies in the health care sector lead to a delay of renewal and modernization investments (e.g. investment bottleneck) and also to a lengthening of the transition of scientific, technical renewals (e.g. therapy, medicine, innovative equipment) (Held, 2012, p.160). Results and insights of scientific studies which are directly produced within therapy are reserved for those patients who are treated in medical centres' (www.kompetenznetze-medizin.de). Deficiencies cause extra hours and slack time simultaneously. A lot of doctors feel overburdened. One out of four works around 80 hours a week- with unforeseeable consequences for the patient. "More than 48 working hours per week, in three out of four cases of hospitalists, are increasingly becoming a risk factor for patients" (www.n24.de). Deficiencies further cause a tendency towards a self-supply of the health companies and inhibit the creation of rational relationships in terms of division of labour (Held, 2014, pp. 95-104; Phoehler, 2010). Market and competition-based elements are introduced with the market however being unable to function with all its rules (Boehlke et al., 2009). What are missing are real prices, market players and concrete buyers for the services offered, and to be able to choose between them respectively, thus actual competition. The competition that is created through the compensation system is not going into the right direction. It is not healthiness as such that is being promoted but rather sickness. One could speak of a "fight" for patients (Held, 2012, pp.147-148).

One can conclude that the survival of the current public health care sector does not depend on efficiency, innovation and effectiveness, because the financial funds are not limited (financing through debts). 19 percent of all public hospitals are bankrupt if measured and assessed by economically

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

criteria, 51 percent make losses (www.dki.de; Krankenhausbarometer 2012), to which all university hospitals belong to (www.vdek.com). The reason for it can be found in the principle of scarcity which is the basic principle for economic behaviour but which is non-existent in this case (SBC). Alternatively, this system also means that social working potential is lying idle while needs are not met pleased. Available work (because there are unlimited needs e.g. research, gain of insights, care, education, prevention, art and culture) is present, but it is not paid for at the moment meaning that a lot of products, goods and services are excluded from the market- a fact which was already absorbed from the economy and the economic theory and was discussed under the term "shared value" as a new concept for the industry and the corporate sector (Porter & Kramer, 2011).

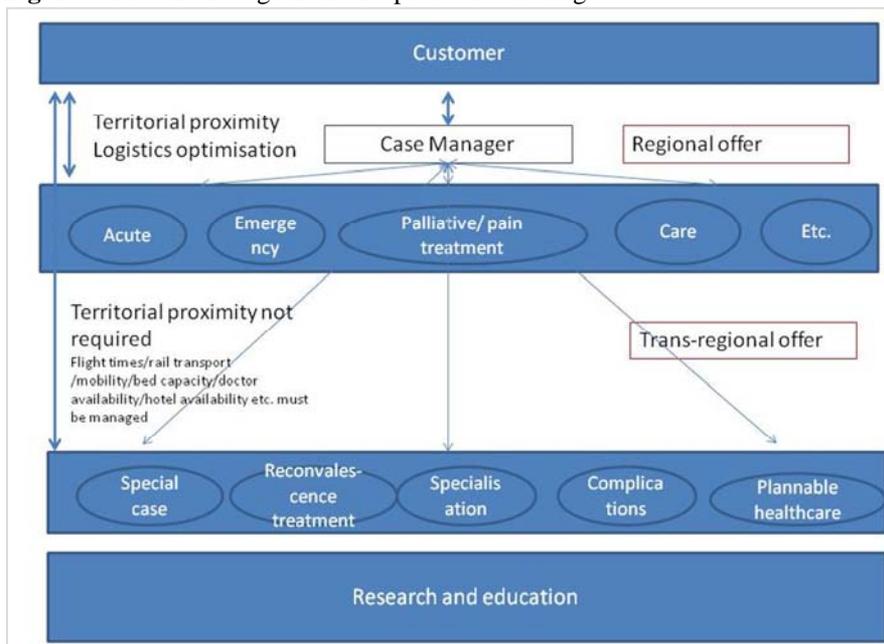

As for the governmental regulation system, the regulation of the market also shows its limits. Major force of the market economy is the utilization of capital while all other forces are subsidiary. According to Schumpeter and aimed at market realization, each innovation is based upon this fundamental drive. The utility of a product is determined by the buyer on the market and is individual and concrete at any time. Economical thinking and behaviour are the fundamentals of the market economy. The public sectors' major force in the utilization of capital indirectly leads to the satisfaction of individual needs (what can be stressed, weakened or is manipulable respectively through marketing). Even less distinct and far weaker than the focus on a direct satisfaction of individual needs, there is the possibility of the public sector to focus on societal needs (e.g. sustainability, health care etc.). Although societal responsibility is accepted as a strong image-factor for private enterprises, it is not a major force as such compared to the efficient utilization of capital. The extreme value of the corporate sector, being based on the maximization of the realization of capital, eventually is the product of limited personal needs (market saturation), limited availability of resources which allows the production for market-adequate prices. Strive for efficiency leads to a progressive edging of people aside from the value creation process (not because of reasons of rationality).

Each hospital requires the respective "freedom" to shape the integrative portfolio management to manage the relevant areas in planning (e.g. medical procedures, resources, products, business areas) under the aspects of risk, growth and revenue. The market economy is the only way to drive the efficiencies in the directly efficient design of the provision of healthcare services. This means that the establishments that were hitherto state-run must be privatised with the related consequences, the risk of insolvency.

Management will act accordingly only when the hospitals have to behave under the market terms.

The next figure shows that there is space for a future healthcare service system that acts on the market without planned economic guidelines, in which each individual healthcare provider can participate, according to the quality specifications of the state regulatory body.

Figure 7. Healthcare region and hospital care offering

Source: own research.

Market economy is not the most suitable system when it comes to shaping society. This applies especially to the healthcare system as a whole. The conditions required to ensure that the healthcare system to be created is sustainable, would therefore be for the state to determine the healthcare regions, but not according to electoral calculation or territorial aspects but rather according to the number of patients, age of the patients, mobility options (infrastructure, such as motorway, railway, airport, etc.) and then advertise for bids from the healthcare service providers. The healthcare system will be organised as a mixture between market and hierarchy. Public Governance appears in the form of a state regulatory body which pos-

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

sesses as a hierarchy and so as a positional authority over sanctions and rewards and which checks the provision of the services, as well as defines rules for the healthcare market, such as e.g. defining care corridors for the patients.

The Institute for Quality and Efficiency in the Healthcare Systems will be introduced here as an example. Since its founding in 2004, the legislative principles and tasks of the institute have been anchored in the Sozialgesetzbuch V [German social security statute book] and have been amended and expanded in further healthcare reforms. The only initiators are the Gemeinsame Bundesausschuss (G-BA) [German Joint Government Committee] and the [German] Ministry of Health. The tasks of the independent scientific institute are to investigate benefit and damage of medical measures for patients, to provide information on the advantages and disadvantages of therapies and diagnosis methods and prepare expert reports on, for example: medicines, non-medicinal treatment methods (e.g. surgery methods), procedures of diagnosis and screening as well as treatment and care guidelines and Disease Management Programs.

Alongside the monitoring of quality for the provision of healthcare services, the service and profitability for the citizen/patient must also be monitored and regulated, whereby it is necessary to define appropriate service levels for the citizen / patient and also define quality standards and monitor their observance by the healthcare providers and where necessary impose sanctions (e.g. revoke the business operating license).

The supervisory board of the healthcare region, which is for example made up of health insurance representatives, local and municipal representatives etc. is personalised and also bears personalised responsibility. The supervisory board has the possibility to advertise for bids to provide a healthcare service in a healthcare region and license various healthcare providers that now compete for Quality and Prices. In turn, these providers can merge to form large networks that act (efficiently) also outside a healthcare region and so also cross-regionally. The citizen is committed per contract to a healthcare provider for a defined period of time (e.g. two years). He has the possibility to freely select a doctor after comparing offers (price and quality) and with a personal Case Manager at his side to support and guide him.

Each hospital must then find its place within the advertised healthcare region with an integrative portfolio management according to various strategic reference points and management perspectives. The management of the hospital from an isolation observation horizon raises the risk of a diffi-

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

cult business situation. Today the following is regulated by the state; how many beds the hospital may have, whether it is part of the basic-regular or the maximum healthcare system, the revenues for healthcare services rendered are regulated by the state and the actual customer does not appear as a customer, he is even completely unaware of many of the prices for the care and services provided, the health insurance is the actual negotiation partner for the hospitals. They negotiate the cases and the prices. Following the new model, the hospitals themselves decide, depending on the core competence, which healthcare services they provide in the integrated healthcare system and with whom they cooperate, which financial model they choose etc. The required healthcare, service and quality standards are defined and there is a direct customer, the patient, who pays for the services. (The prerequisite would be a health insurance that covers a defined healthcare service corridor but does not constrict the patient as the customer). This requires, alongside the integrative portfolio management, innovative service management to develop new business areas and finally effective management with interdisciplinary supply chains and also integrated supply architecture. This in turn requires standardisation and industrialisation in order to provide the patient with personalised medical care that is affordable, highly modern and permits the healthcare provider to generate the required profits. The prerequisite here would be to include the entire resource consumption into the price of the healthcare services, and not, as is the case today, only to calculate the current expenses. Determining the location of the hospital, in other words, the question "Where do I want to go" can only be answered if the strategy, the way there, is geared to business.

It is therefore important that the hospital management rises to the challenge of value innovation as a growth option using newly defined benefits from the point of view of different patient groups and so develops new areas for growth for itself. The prerequisite here would be that the incentive structure in the healthcare system were turned around and thus connected to a radical, new definition of the business purpose. Only then will new growth areas be opened up for the hospital. Still today growth in the hospitals means: Equipping hospitals, securing healthcare assignments and bed numbers, exploiting bed capacities and gaining patients that require the most expensive operations possible. A reversal of the incentive structure would lead to a change in the purpose definition of the hospitals and from then on the "Value of Health" and not longer the "Value of Disease" would be at the centre of the entrepreneurial activities.

Conclusions

The analysis has shown that the private hospital groups are the only players that have the necessary innovation resources and also the necessary market pressure to be innovative. But, the negative consequences of the dominance of these private corporations have been described. Government hospitals are arrested in their structures. An outdated planning model, the soft budget constraint, the corporatist system of organization and lack of entrepreneurship are the main causes of the defects in public hospitals. All described elements tend to cause an erosion of the corporatist, organized health care sector on its way to classical bankruptcy and towards a private system within the scope of service provision while preserving the model of a solidary health insurance financing. Here, the state keeps on disappearing from investment financing of the hospitals. The employer's contribution regarding health insurance, locked up through the political decision-makers, allocates the rising costs to the insurant even greater.

Simultaneously, the growing offer of direct and chargeable health care services is only partly paid by the insurance. Step by step, the patient becomes the financier of the health care system subsequently leading to a point where he is a player and customer in the health care market, thus puts pressure on the system himself. The patient becomes the subject rather than being the object which means that he is put in the position where he is able to make decisions rather than being the object of other stakeholders' actions. More and more active patients demand for:

- Transparency of information towards the players (information about doctors in the internet and rankings of hospitals) and focus on his needs.
- Transparency of performance/ quality (therapy -> cost/ benefit evaluation)
- Cost- and efficiency transparency therapy -> benefit/ cost evaluation).

It becomes evident that working competition requires the same basic premises for all players. Therefore, they have to be set and must be applied nationally (antitrust law).

On the contrary, a supply that fits the needs must be oriented on the differing social and local/regional needs, thus requires a decentralized management (Böhm, 2008, p.74). The central question, subsequently, is how the three principles (1) an efficient and market-oriented organized health care sector, (2) the social principle of balance of the public services in the health care sector (3) and the local/ regional reachability of the health care services are organized and linked with each other. General problem solving

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

will only occur if management in the health care sector orientates itself on the principles of "hard budgets". „The entry of non-state companies and private capital must be combined with reinforcement of government regulation and control.” (Kornai & Eggleston, 2001, Cap.7) “The way must be opened for the entry of non-state forms of ownership, among other reasons because there are improved changes of hardening the budget constraint on private business. It is desirable to have supply-side competition in the hospital sector.” (Kornai, 2009, p.133) A first problem-solving scenario for the German regional health care supply was worked out (Held, 2014), which has the citizen being a shareholder as its central point. Here, the market in the form of a privately organized health care service provision is the mean (coordination tool) and a union or a stock company stands as the medium. The following basic principles determine this scenario.

- Health is not a common good; supply of health care is a service.
- The patient transforms from being the object into being the subject (transparency/ service/ quality/ costs).
- Replacement of SBC (soft budget constraints) of the central planning with „hard budgets“.
- Industrialised service structures (Customer Care, Delivery, Resource Management) (Held, 2012, pp. 234-239).

The concrete forming of this model like for example the forming of public governance, civil governance, the relations of distribution and – mechanisms need further evaluation, research and discussion.

**Reasons for the Changes of the Concepts
of Human Nature in the Economics Exemplified
on the Contemporary Trends***

JEL Classification: *B5*

Keywords: *concepts of human nature; social trends, economic anthropology; heterodox economics; economic psychology*

Abstract: The main objective of this paper is to characterize the key trends responsible for the changes of the concepts of human nature in the economics. The methodology is both deductive (conclusions from theories developed within social sciences and humanities) and inductive (observation of current trends, which according to the theory are potentially responsible for those changes). Basing on the insights of psychology, philosophy of science, sociology, and cognitive science main potential forces are deduced. From the observation of actual trends, the basic contemporary factors responsible for the changes of the concepts of human nature are distinguished. Those can be divided in three groups. The first group contains factors focusing on the advance in knowledge about the human being, occurring within the general and specific sciences dealing with man (e.g. psychology, sociology, philosophy, cognitive science). The second group of factors includes the increasing complexity of the social processes. The third group refers to those social trends, which are responsible for altering understanding the world, which in turn results in real changes. Virtualization of life, greater sensitivity to human and envi-

ronmental issues, increased contacts with other cultures and religions, greater sensitivity to the existing social injustice are some of those factors. Basing on those results, the reasons for growing criticism of traditional, orthodox image of man in the economics are discussed and the postulates of the heterodox economics for modifications in the concept of human nature, which reflect the changes taking place in society.

Introduction

The concept of human nature (image of man, concept of man) is a topic, which isn't discussed enough in the economic literature comparing to its crucial meaning for the development of the science. Only some of Polish (Stępień & Szarzec, 2007; Horodecka, 2014a; Turek, 2010; Zboroń, 2010; Horodecka, 2012c) and foreign (Schechner & Zsok, 2007; Bernd Siebenhüner, 2001; Manstetten, 2000; Woll, 1994; Biervert, 1991; Starbatty, 2000) economic literature is focusing at this topic and stresses its meaning for the development of the science.

Therefore the issue of changing concepts of human nature in the economics stays in focus of this paper. The main objective is to differentiate and characterize the main forces responsible for the actual changes of the concepts of human nature.

In order to achieve this goal at first the concepts of human nature will be defined. Then the basic factors responsible for those changes will be evaluated. First of all the changes of the concepts of human nature can be perceived as a result of changes occurring in the contemporary society. Living in the society which is considered as a society based on knowledge (.), and in the economy, called economy based on knowledge the changes in the state and art of knowledge (growing meaning of so called tacit knowledge and who-knowledge Siesfield, p.116-117), which are very prompt, have a crucial effect on the changes of our way of perceiving human being. Another essential factor is the growing complexity of the social changes, which is characteristic for contemporary global processes. Last but not least there are some changes, which result in changing the image of world, which can be perceived as a part of the concept of human nature, which will be explained later.

Methodology of the research

The methodology is in first part a deductive one basing on some conclusions derived from theories developed within social sciences and humani-

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

ties. In the second section it is basically inductive, focussed on observation of current trends, which according to the theory are potentially responsible for those changes. Basing on the insights of psychology, philosophy of science, sociology, and cognitive science main potential forces are deduced. From the observation of actual forces basic contemporary factors responsible for the changes of the concepts of human nature are described which can be divided in three groups.

General model

The concept of human nature is a form or scheme, which is applied by human being to deal with the complexity of the world. They help the individual to decide, what action has to be conducted (see: psychology), and what signals are considered as important while dealing with the outside world. Those concepts can be compared to glasses put on by individuals and societies to perceive the outside world. In the science they play similar role, but they take more explicit form. The everyday concepts of human nature have more implicit character.

The concepts of human nature are naïve philosophies, or naïve theories of the individual about human being (Oerter, 1996). They can be referred as well as subjective theories created in order to understand the world (Klewin, 2006, p. 10), which have rational and irrational parts (Groeben & Erb, 1997; Groeben, Wahl, Schlee, & Scheele, 1988). Although they are principally belief systems of the individual (Oerter, 1991, p. 19), which create personal frames of values and convictions of the individual (Oerter, 2007)¹, they have as well some common contents, which encompass traditions, value orientation, overtaken answers on basic questions of life. Other ways of speaking about those concepts is treating them as implicit theories, ethno theories, indigene psychology, in spirit of constructivism According to constructivism people aren't perceiving this world but they rather construct their world. To be able to understand ones world it's necessary to understand this construct of the people (Kelly, 1955/1991). The psychological explanation of this fact is that person's processes are psychologically channelized by the ways, in which he/she anticipates events (John, Robins, & Pervin, 2010).

¹ According to Fahrenberg, 2006, 14: basic beliefs of individual, latent constructs, beliefs about religiosity, belief in God, belief in the hereafter, free will, ethics, responsibility, basic attitudes to meaning, values, goals of life of individuals.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

The concepts of human nature change usually on all their levels and in all their dimensions. We can differentiate following levels of the concepts of human nature: individual level, social level and worldview, whereby the individual world can be subdivided in following dimensions, which can be referred to as the body, the soul and the mind. They stay for following aspects of human being – his/her behaviour, motivations and meaning respectively (see: Horodecka, 2014c).

Those concepts are a part of a system, in which we can differentiate (such a differentiation is described by Czaja, 2012a, p. 13) real changes in the environment (like changing patterns of behaviour, social structures, economic problems or inequalities, environmental problems and so on) and logical changes, which result from the changes of information, and knowledge. Those changes impact directly and indirectly on our perception. It is so, because they impact not only on the things we perceive, but the way of perceiving – ‘glasses’ that we put on to see the world. Those glasses are metaphors, concepts, schemas we use to perceive the world. The different concepts of human nature are in this sense as well such glasses.

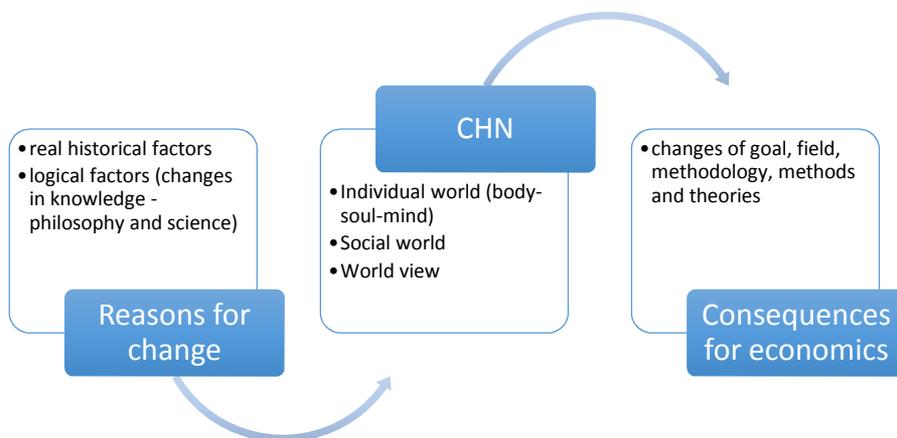

There is a lot of psychological and philosophical literature explaining how the concepts of human are constructed. It’s usually explained in the way the more general concepts – creation of schemas is explained. This occurs in two-ways: top-down, basing on schemas (a concept described by: Neisser, 1976), which impact the process of perceiving or bottom-up, basing on input by senses.

Generally speaking the factors can be subdivided in two groups – one refers to internal factors like for instance personality, or more deeply genetic factors, which influence a particular way of perceiving human being. The second group, which is far more interesting for economics are environmental factors, which influence the way of thinking and perceiving the reality. This group entails for instance existing technical inventions, which can provide dominating metaphors for perceiving the world. Like for instance perceiving human as a perfect constructed mechanism by Descartes [1596–1650], during beginning of Enlightenment or as a machine during industrial revolution (since mid of 18th century), or explaining communication processes between people using metaphor of a phone call (in Shannon model of communication in the mid of 20th century), or a computer for explaining how human mind works (since 80-es of 20th). The knowledge bases on such metaphors and uses them in order to explain phenomena. In such a sense concepts of human nature in technics and economics interact (Detzer, 1999)). Later this knowledge is as well used in order to make anthropologi-

cal presuppositions, which means that we use as well the existing psychological knowledge in creation of our private concepts (Bahrtdt, 1961, p. 2; Behnke & Witte, 2008; Witte, 2008).

The changes in the way of perceiving the world are developed through interaction between the individual and the environment. In this sense they have both individual and common parts in the image of man. In this sense the image of man is a communication instrument (see: Rollka & Schultz, 2011). Therefore they change permanently.

Figure 8. The changes of concepts of human nature: reasons and consequences

Source: the differentiation between logical and historical factors is introduced by Czaja.

The progress in the knowledge about human being and in other disciplines

How the theory explains the connection between growing knowledge and changes in the schemas we use (and therefore concepts of human nature). Growing knowledge and experience deliver to person new insights about the nature of things and persons. It provides a human being with new explanations, metaphors, and different causal relations so the relation cause-consequence is perceived in the different way, which makes necessary to adjust the concept of human nature. For instance knowledge that human are motivated not only by money or material incentives (A. Maslow, 1943, McGregor McGregor, 2002, 2006 (1960)), that they need to see a

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

meaning to their lives (Frankl, 1997), or that we are influenced by the behaviour of other persons in unexpected high grade (a contribution of the social psychology experiments, like Milgram (Milgram, 1970) or by-stand effect (Latané & Darley, 1970) – makes necessary an replacement of the concept of human nature.

The knowledge constitutes the map we use to perceive the world more detailed or sometimes replaces some concepts with others, makes some concept disappear (for instance the idea of ether) and is responsible for the emergence of other. Without those maps, we are unable to perceive some things. Without having knowledge, words for something can't discover, as Wittgenstein said ("The limits of my language mean the limits of my world"). Our maps impact on that what we are ready to see, and what we won't. Schumacher in the Introduction to his book 'Small is beautiful' refers to such maps, which can limit our way of perceiving not only the world, but as well human being (Schumacher, 1973).

The progress in the knowledge of human being leads step by step to the changes in viewing human being. Those changes impacted as well the emergence of new paradigm in the philosophy. This progress can be observed in many fields of knowledge about human being both generally (philosophical discourse) and specific (psychology, sociology, social psychology). These new insights and ideas spread all over the world in the current era of information revolution in a very quick manner. Generally, all subjects taking economic decisions like households, employees and members of other organizations (sportive, cultural) are confronted with this new knowledge.

How is this new knowledge, and new aspects of human nature (like for instance the sense of being embedded in the nature, or perceiving various motives instead of only material egoistic ones) transferred? Many of new concepts of human nature are learned through everyday interactions between social groups and individuals, social institutions and individuals (Rollka & Schultz, 2011). Each social interaction provides a platform for exchanging concepts of human nature. In this way the concepts are implicit or sometimes explicit exchanged (see: results of the research done Horodecka, Martowska, & Wrocławska-Warchała, 2014, Fahrenberg, 2010, Oerter, 1999). Those concepts are implied in social acts and acts of speech.

As soon as the number of those interactions grows (sociology of communication), because we have much more contacts not only in person, but through the introduction of new communication channels by technology like virtual contacts for instance. The number of contacts with persons out-

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

side one's cultural background grows as well, because of such social trends like growing mobility for work, social mobility (passing through the borders between social classes and milieus see: script diversity), migration to other countries.

The organizations as well play an important function as transmitters of the concepts of human nature. Organizations use particular concepts of human nature in an explicit or implicit way in their visions of organization, which then influences on the managers and employees working at this company (leader- follower mechanism, see: Ehrhart, 2012). Persons having leading positions play a particular role in this influence². This influence can take a form of preferred leading style. This is the case in non-formal organizations and formal one, oriented on profit and non-profit. Often one particular vision of human being is connected with the activity of such an organization (for instance there is a different approach to the human being in a bank, in education, in medical care, in construction enterprises and religious and volunteer institutions). However an image can be a consequence of some social movements, which encompass different trades. For instance ecological organizations can be lead in different trades (they don't have trade limits). They make their presence in different parts of the economy starting with ecological food, through ecological and green portfolios in banking sectors, green dwellings, religious and social organizations and fair trades³.

Other channel of social interaction, other transmitters of the concepts of human nature are the media, arts (Hartl, 1999), politics (Lenk, 1999), society in general (Endruweit, 1999) which usually represents some ideological elements and depicts the power distribution in the society (this was an idea of Frankfurter critical school developed by Adorno, Horkheimer, Marcuse, see: Horkheimer, Adorno, & Noerr, 2002; Hylewski & Burdzik, 2014; Marcuse, 1964; Hylewski & Burdzik, 2014). Therefore it was so easy for long time to spread the image of man as consumer, oriented on maximization of utility, individualistic etc. As a consequence a demand for products grew, which neither met real needs of the individual nor of the society. It loose as well its contact to the real needs, resembling more wants (see: differentiation of needs and want by humanistic and Buddhist economics, M.A. Lutz & Lux, 1979). The entertainment part of media as well delivers

² This is because of the authority, a contact with this person, dependent or an particular managing style

³ Products supporting trade basing in equal rights, which enable third world countries to participate in profit.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

a particular concept of human nature, reflecting social changes in the society, and on the same time political correct image, respecting interests of people having power in the society. Film maker present not only the artistic ideas of screenplay writer, but as well are interested in the commercial success of the movie adjusting the play to the expectations of the receiver, so that the movie would reflect humans desires concerning who they want to be, or are. The same concerns contents delivered by the TV, which transmit a particular concept of human nature – a consumer, willing be always young, efficient (see: Funiok & Angerer, 1976; Weis, 1993; Pirner & Rath, 2003)

Another transmitter of the concept of human nature is as well the primary, secondary and tertiary and growing meaning education and growing meaning of further education, and self-education (Hentig von, 1999). Reading books, watching informative and educative media programs, podcasts, videos, inter-active programs, assisting self-courses online, and other online services are activities, which as well are growing in recent times.

Therefore each participator of economic processes, the economic subject has his/hers particular idea of that who is the human being and this knowledge can impact on his/her behaviour, or motivation. The kind of this knowledge (for instance scientific, or everyday, transmitted by ads, or news etc.) depends on activity and choices of the person and his/her environment (kind and intensity of contacts, conscious or unconscious choices).

This knowledge about concept of human nature reaches not only economic subjects, but economists as well. The growing interdisciplinary character of conferences, courses offered at universities (for instance new forms of delivering a lecture on economic subject, collaboration with specialists coming from different disciplines like psychologist, sociologist, engineers, who accompany economists), intercultural character (the percentage of well-known economists coming from other countries than Great Britain and United States⁴ is growing, this is confirmed by the tendency to give Nobel to people coming outside of those two countries or even outside of the economic discipline, Czaja, 2012c).

Although the influence of other disciplines on the economics and on the economists is not something new, the intensity of this dialog and creation of platforms of interchange haven't been so vivid before. The impact of

⁴ See: Financial Times, 21.03.2013 r. the paper written by the Reuter's director about the growing importance of scientists coming outside of traditional scientific centres like Great Britain and United States, France or Germany. The meaning of China, India and other countries when it comes to economics or other disciplines is growing.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

other disciplines is enabled by creating structures of cooperation (interdisciplinary scientific or even didactic projects), which lower obstacles to the research on the borders between disciplines.

First such a discipline, which impacts on the economics and on its concept of human nature is the psychology. The progress in the psychology changes the perception of a person by the society and by economists. Especially the behavioural economics adopts the psychological research to the economics. To the fathers of this economic school counts a psychologist, who who obtained Nobel-price in the economics – Kahnemann, who worked together with Tversky, see: Tversky & Kahneman, 1982; Kahneman & Tversky, 1979; Kahneman, 2011). Humanist economics is another economic school, which collaborates strongly with the psychology. However it bases on different psychologist paradigm. Whereas behavioural economicsc bases on cognitive-behavioural approach to psychology, humanist economics is influenced by thoughts of some humanist psychologists like Maslow and Rogers (A. Maslow, 1943, 1970, 1994; A. H. Maslow et al., 1966). The thought of those psychologists was further developed and adapted to economics by: Beaudreau, 2012; Brockway, 2001; Cook, 2001; Mark A. Lutz, 1999; M.A. Lutz & Lux, 1979; McCain, 1990; Solomon & Collins, 1986)⁵.

Another economic school, which collaborates with the psychology is neuroeconomics (see: Camerer, 2008). The psychological paradigm is in this case the cognitive psychology (see: Engelkamp & Zimmer, 2006; Thagard, 2005, Groome, 1999 and Bandura, 1986), which aims to discover how information is processed by the mind. This part of the psychology is working very interdisciplinary with informatics, linguistics, philosophy and neuroscience. The economics basing on the results of cognitive psychology (or cognitive sciences – this term is better adapted, because shows the interdisciplinary character of this science) is practiced not only within neu-

⁵ The development of humanistic psychology lead as well to the development of new concepts of man, which based on the critics to two of other prevailing paradigms in psychology – behavioural and psychoanalytical. According to behavioural concept a human being is treated mechanically as a black box, which is subordinated to the law of looking for appraisal and avoiding punishment. The psychoanalytical approach is assuming the human being as a victim of his/hers self, which consists of contradictory forces (ich, es, Ueberich). The humanist paradigm on the contrary stressed an autonomous character of human being, his/her streaming for self-realization, or even transpersonal experience (last paper of Maslow). Moreover they are first attempts in putting the hierarchical character of human needs what took shape in the so called Maslow pyramid of needs A. Maslow, 1943. It was as well first paradigm, which distinguishes altruistic needs of human being

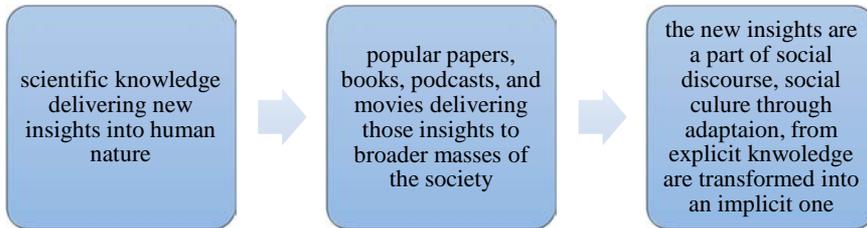

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

roeconomics, but as well evolutionary economics and within economic psychology (Tyszka & Przybyszewski, 2006), or evolutionary economic policy (Meier & Hauray, 1990; Meier & Slembeck, 1998), see as well: Oetsch, 2007. Due to research done by cognitive science the role of expectations in human behaviour could be explained better. Another aspect was the different approach to the rationality, which is called here 'bounded rationality'. The rationality is bounded because it is often replaced by so called 'fast thinking', which is not different heuristics, which facilitate his/her orientation in the world, taking fast decisions. This on the same time demystified his/her tendency to taking non-rational decisions (compare research done by Kahnemann& Tversky: Kahneman, 2001, 2003, 2011; Kahneman & Tversky, 1979, 1984). All those concepts were pointing to the limitations of the economic man. The economic man with his fixed utility function independent of the influence of other persons, relatively stable in time⁶ didn't match to the real human. Especially psychology of advertisements and media elaborated practical consequences of such new concept of human nature. Those practical consequences were pointing for instance on the possibilities of manipulation of people (through the conditioned reflexes and operative conditioning) and by creating of new needs.

⁶ Within the economic concept of human nature there lacks some cohesion. On the one hand the stability of preferences is assumed and the maximization of the utility. This implies that human being can resist manipulation and creation of false needs, in order to reach the utility in long time (). On the same time it means a kind of independence from the environment in shaping and covering the needs, what is congruent with the assumed perspective of research individualism. On the other hand the economic man is referred to as a behavioural man, reacting to the impulses coming from the environment, and adjusting to this environment his/her decisions. This is one of assumptions for exerting the macroeconomic policy by the state, and explains on the same time reactions on the signals coming from the market. Most of all the focus lies here on such signals as a price and quality. Other signals are often denied which can affect the utility function. Those signals are for instance advertisement or the context. Depending on the context one object can appear to us as more utile than other.

Figure 9. The impact of the altering knowledge about human nature on changes in the concepts of human nature

Source: own.

Many psychological discoveries made it possible to verify the ideas developed earlier by philosophers. One of such example was the discovery of emotional intelligence, which was an important addition to the rational intelligence (see works and tests developed by Stern, 1912), measuring primary the velocity of transforming the knowledge by human⁷. Emotional intelligence is a form of composite intelligence (other form is for instance a social intelligence), which measures the ability to decode the emotions and use them by solving everyday professional and specific problems. One of its elements is the empathy. The ability to empathy was confirmed by scientific inquires during 90-es of the last century called mirror neurons. Practically it confirms the idea of David Hume (who refers to the sympathy as a primary motive, influencing moral and social behaviour, Hume, 2000, 2007) and Adam Smith (Smith, 2000) that people are influenced by emotions of other people. This inquiry undermines the assumption, which is made about the economic man, when it comes to his way of approaching his/her own goals, not paying attention to others. Therefore behavioural economics and other economic schools (for instance: feminist economics, or ecological and even evolutionary economics or care economics) adapted a different concept of human nature. It is here assumed that a human being even if in some aspects may behave egoistically, is shaped as well by altruist motives, which can even ensure the survival of the individual in end effect (like Dawkins maintains in his 'Egoistic gen', Dawkins & Skoneczny, 1996). Further development of evolutionism provides new understanding of the egoism. The evolution is not about survival of the strongest, survival of the individual, but about survival of the gen, which

⁷ There are as well variants of the intelligence tests, which don't focus on the velocity, but only the ability to find a solution, regardless time needed.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

implies taking care of own children and relatives. This gives an important argument for explaining the necessity for caring for next generations (to which the gen is passed). Previous understanding hasn't provided any explanation for the care behind own individual interest.

The social psychology as well refers to speaking about group-solidarity, altruistic behaviour rescuing members of the particular social group, even not related to one other, which ensures a survival of the group as a whole. The progress in sociological knowledge influences as well the changes in creation of the concept of human nature. Especially the insight, that human being is a social being and is influenced by the society. The social thought was as well helpful in understanding of the role of the society and social institutions in the creation of social roles, interactions, habits and interactions. The progress in knowledge about social communication as researched by sociology, social psychology and communication science has had as well a meaning (see as well: Horodecka, 2015; Horodecka et al., 2014). Furthermore the role of media was explored. The concept of human nature can be even as the basis and goal of all communication (Rollka & Schultz, 2011). The next important discovery influencing way of perceiving the human was discovering the meaning of the gender and the culture and their impact on the communication. This showed how far of the reality lie the assumption of shaping the preferences independently of the environment.

Another psychological discovery concerns therefore neurotransmitters. Up to the beginning of the 20th century, it was assumed that the synaptic 'communication' in the brain has an electrical nature. The discovery of the synaptic cleft made by Ramon y Cajal (1852–1934) allowed for the formulating of chemical way of communication. In fact Otto Loewi (1873-1961) proved, that this communication is made by releasing of chemical reactions.

The same concerns the progress in the anthropological knowledge, which puts a new light on human motives and ways of human behaviour in different cultures. The special meaning has here the development of the philosophical anthropology. For its development counted different philosophical schools. They were an impulse for the change of the way of looking on the human being. Here some examples:

Existentialism assumes that the human being chooses himself/herself by taking decisions. Human being is not an already shaped being, but gains his/her humanity by choosing him/herself (Kierkegaard, 1946, Heidegger, 2001, Sartre, 2012). By adapting this way of thinking to the needs of eco-

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

nomics, we can say that human being chooses more him/herself than objects, and this choice impacts his/her further choices. The further consequences it, that such human doesn't have any ready list of preferences, but that are shaped within the process of human development and are shaped by each choice made. Although some authors (Lück, 2009, p. 162) don't agree that, that that existentialism of Heidegger or Sartre has much in common with humanist psychology, the former one is still close to some of existentialist like Camus. Especially the idea of self-development for the society sake.

Phenomenology assumes, that our reception depends not only on what we in fact explore, but on ourselves, our cognitive structures. The human is not only a passive receptor of the reality, but the reality is embedded in his conscious processes. Phenomenological method as developed by Edmund Husserl, Theodor Lipps and Ludwig Klages is used by humanist psychology, and humanist economics as well. It can be characterised as a close and judge-free observation and description of phenomena, which include as well the self-observation, as soon as it's assumed, that the observer impacts on the phenomena. It focuses not so much on the discovery of rules, which in fact mean reducing the reality to some ex-ante assumptions, but values as well a description. Phenomenological school provided useful tools to the analysis of social and political events (Foucault, 2012). This gave motivation to the development of constructivism (constructionism), which maintains, that that what we are researching aren't the facts but constructs of the reality, which depend on our perceiving of them (the concept of human nature is as well such an construct). Constructionism demands from us another way to research the 'social facts'. Instead of researching 'objective facts', which according to constructionism aren't objective, we should explore the narration (discourse method), which allow us for discover, what image of world and what concept of human nature we base on, as soon as they shape our reception of events. This provides not only a new understanding of the concept of human nature, but as well additional methods practiced within humanist economics for instance.

Close to constructionism stays the philosophy of mind, which stresses as well the role of human mind. In order to understand and discover the phenomena outside – like the human and his/her environment, we have to know its role in understanding of the phenomena. The mind creates the world, in which we exist. This philosophy can be reflected by the cognitive psychology and in research of learning processes which are done within cognitive studies (Duch, 2011; Duch, 1999)

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

Structuralism is another philosophical school, which impacted our way of seeing human nature. The structuralism can be understood as the way of understanding of the social reality and the language by looking for some meta-structures in it (De Saussure, 2001). The psychology has adapted this basing on research done by Chomsky (Chomsky & DiNozzi, 1972; Chomsky, 2002). Due to such genetic equipment with those structures, the child is able to learn how to speak. A way of perceiving economic phenomena depends as well on the structure embedded in us. The reality has only a secondary character as soon as it is subordinated to structures we apply by perceiving it.

Another philosophical school is the evolutionism, which impacts on the way of perceiving a human being. It perceives the reality as being in the process of development. Other philosophical schools which focus on this changing aspect of the reality is for instance the philosophy of process (Whitehead, 1979; Whitehead & Lachmann, 2000). Other is the Lebensphilosophie ('philosophy of life'), developed among others by Bergson (Bergson & Andison, 2007). It can be characterised by the conviction about a complex nature of the processes occurring in life. They can't be reduced neither to simple mechanisms nor to perceiving of the reality as a sum of its elements (Horodecka, 2011). The evolutionary way of perceiving the economic actor and his/her work – economy is a basis for other direction in economics – evolutionary economics. Ecological economics bases as well on the holistic way of perceiving of the reality, and manifests itself in the 'philosophy of life', paying regards as well to the evolutionary processes⁸.

Next philosophical school is a philosophical personalism, which focus on the person, on the human subjectivity or self-consciousness, experienced in a person's own acts and inner happenings—in "everything in the human being that is internal, whereby each human being is an eye witness of its own self" (Wojtyła, 1993). One of the compatible direction is the philosophy of dialogue, which opens the perspective on the essence of the interpersonal communication, within which persons get the possibility to transcend themselves. The focus on communication (an example for this philosophical direction could be 'Ich und Du', 'I and Thou' of Buber, 1995) as a dialogue with one equal person, the acceptance of other as they are without instrumentalizing changes the way of looking at human being. The person discovers him/herself deeper 'I' (for Buber this deeper 'I' is God – the 'Thou') through the dialogue with other person or with the Na-

⁸ One of the creator of the 'life philosophy' – Bergson is famous from his book „creative evolution”, see: Bergson, 1911.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

ture. On the contrary - objectifying of people and nature, the individual departs from him/herself, entering into the world 'Es' = 'It', which compounds from the empty world of objects, which passes, without any meaning. The influence of this philosophy can be seen in the stressing of the meaning of communication in understanding of human nature. It is close to the humanist and transpersonal psychology and economics and their way of perceiving a person – making a focus of the economic analysis but still embedded in the society, and self-realizing itself within the society.

Further research, which contributes to the change of understanding of the concept of human nature is the provided by the communication studies and management science. Within sociology of communication we can observe the growing interest in forms of communication, which go beyond passing of information, but include as well the 'true meeting' (Horodecka, 2015). Within managerial science as well new concepts were developed, which base on the psychological inquires discussed before. As a consequence many diverse concepts of human nature emerged accompanied by the changes within managing styles.

Summing up, the development of knowledge within different disciplines allowed for a more complex and deeper understanding of the human nature. This resulted in the changes of the concept of human nature in those sciences, generally speaking in all social and humanistic sciences and in the economics as well.

**Growing complexity of all processes and other social trends
contributing to the change of the worldview and human nature**

Concepts of human nature change not only because of the changes in the knowledge about human being but as well, because of the changes in the human environment. One of the major trends impacting on the changes on the way of perceiving of human being is the growing complexity of social processes. This tendency is reflected by some economic schools to different extent. Especially the behavioural economics and neuroeconomics are pointing to the growing complexity of the social and economic processes. The person encounters more and more complex problems and have to deal not only with the simple optimization functions, like the rationality of economic man assumes, but has to refer to the emotional rationality as well – build heuristics, some simplifications, which help him/her to take decisions (see: Kahneman, 2001, 2003, 2011; Kahneman & Tversky, 1979, 1984). In the situations of growing number of cultures, contacts, such simplifications

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

allow for a fast understanding of situations. On the same time it leads to the development of many filters, which not always allow for making optimal choices, according to Kahneman Tversky, they aren't likely to be optimal. One of such simplification is the model of man. It allows for sorting people in groups and faster assuming to them some characteristics, and formulating of expectations. Doing so we refer to different concepts of human nature.

Actually more and more goods, and services, which have been 'produced' before outside of the market and outside of what was considered as 'economic system', get a research domain of economics, like for instance the housing, teaching, caring, health, spiritual development. This means a growing meaning of those sectors for the whole economy and for particular companies.

Many scientists and researcher during the last decades stress the growing complexity of the processes occurring in the economy, politics and society. Scientists exploring crucial tendencies, which impact on our environment point to the fact, that the growing complexity is one of major characteristics of the post-industrial epoch, the information era and knowledge. Research on the problem of complexity grew on importance within the social sciences. The growing tendency to discern social and economic phenomena in their set of relations, and on the same time progress in specialization makes different disciplines analyzing the same phenomena out from their scientific perspectives. This is an incentive for the formation of multi-disciplinary teams investigating a phenomenon from many different perspectives. Here count for instance the creators of the system theory like Parsons, 2003 (functionalist approach), Luhmann, 1994 (structuralist approach) as well as theories of the evolutionary nature (as for instance Witt, 2008; Nelson & Winter, 2004; Dopfer, 2001) which base on the idea of the complexity and ways of dealing with it.

How we can characterize best the phenomena of growing complexity?

First of all the number of interaction between individuals grows (number of contacts between persons and their quantity), which is due to the growing number of social roles which we fulfil in the society and growing social mobility, which includes work mobility (changing working place), changing relationships. The measure of those changes may be the average period of employment in one place, number of divorces, number of organizations, we belong to, time spent on virtual platforms (on phone, virtually, on internet). Growing number of interactions enlarges the number of mutual relationships between people.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

Secondly the growing complexity can be seen through the observation of the velocity of changes in social and economic relations. This can be observed in the number of contacts per one persons, the diminishing period of life of the company, transformations within the company, which means a change in lives of all engaged persons and the necessity of building relationships within new company for each of employee, entering into contacts again. Moreover the rapid social changes can be seen by the product life, which is getting shorter. This implies the necessity to create new, different one, which have impact on consumers, speeding up the tempo of changes, and rising expectations towards changes.

The innovations are introduced faster, which as Schumpeter describes may have an impact on grave changes of all economic systems. Schumpeter refers here as well to the possibility of the fall of the capitalism (Schumpeter & Röpke, 2006)

The complexity of the processes occurring in the environment of the person, structures in which he/she is functioning, roles, which he plays, grows. This all requires a creation of such an image of man, which can match to this role.

One other factor leading to the change of the worldview and concept of human nature is the confrontation with other cultures, resulting in the need for accepting them. It requires for instance a change of the prevailing thesis of the superiority of Western culture, and this in turn means changing vision of the world (Sztumski, 2011).

The growing contact wit other religions as well may cause some changes in the way of perceiving the world and human nature. Living next to other religions, the contact with them, also induces changes in approaching other religions. Some views, which prevailed for centuries putting own religion above all others can't have a stand anymore. Worldviews and concepts of man have to get more tolerant and flexible, more diverse in order to maintain peace. The changes concern as well religions themselves, which get interested one in another (World Parliament of Religions is one of possible examples). Within a catholic religion there are some changes as well. For instance the concentric model, according to which the Catholic Church has the fullness of salvation remedies, whereas other religions are on further concentric lines, far more away from the Truth than the Catholic Church, has been replaced by other solutions. The worldview and human nature concepts have to adapt to such changes, allowing for diversity.

This interest in other cultures and growing interchange with other cultures is reflected as well by the economics. The Anthropological Econom-

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

ics points for instance to the fact, that even the theories we have about the market are relative. Those theories refer primary to the western culture, and don't have necessarily an universal character beyond the culture, as it is often suggested implicit by the IMF. There are some doubts regarding the superiority of the market economy, which was developed in the West. It is considered by some economists still as far from being the best, and may even be harmful in a different cultural situation. It is not possible to look through the prism of our assumptions and 'glasses'. For instance assuming the existence of market and looking on economical processes through this assumption, is similar as looking through particular 'glasses' on a problem.

There are two basic approaches to the anthropology – individualist (Malinowski, 1944; Malinowski, 1994) and collectivist, which perceives the society in a holistic way (for instance communitarists -Etzioni, 1995). Wearing some particular cognitive 'glasses' may change the outcome, especially when they are 'glasses' (cognitive constructs), which match so well the situation of the society and western society.

There are also phenomena in the surrounding world, which essence didn't change much, but their reception did! Thus, for example a poverty, violation of human rights, unequal distribution of wealth has always been existing (even though, for example, the level of relative poverty is deepening, but absolute poverty decreases), but only now people started actively look for global solutions of them. People started to realize the gravity of problems mentioned below. This leads as well to some changes regarding how we think about the world and an individual. In the case of growing sensibility to social problems, the concept of human nature changes as well. It's for instance assumed that a person is not only responsible for his/her own good, but for the good of others, the whole society.

Growing sensibility to ecological issues changes for instance the attitude to so called free resources. They aren't considered any more free. It is as well assumed that they require individual and societal concern about them. Such an engagement for the nature is often contradictory to the self-interest of the individual. It seems therefore necessary to assume that the human being is not responsible for its own interest, but for others as well.

The last two examples make it clear that goals of people are overcoming their own interests (care for people with whom the individual probably doesn't get in contact, and the care for the environment, even when it means larger costs for current generations and profits are most of all be received by the future generations. This again is contradictory to the assumption on which grounds the economics, that people focus only and pri-

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

mary on their own interests. For the protection of environment many people are spending private resources (buying ecological products, consumer goods for instance), as only if they have to fulfil the requirements put by the law. It seems that the will to economize costs is not the only motive, which decides about so called 'green investments', green products, which don't yet pay back to the investors. The engagement can be perceived as the growing importance of the value, which has got accepted by the environment, the estimation for the nature and the responsibility for future generations. In this context we use to say about the growing ecological consciousness (Papuziński, 2008). The attitude to animals has changed as well (Leks-Bujak, 2009). People refuse frequently to treat them in the same way as other goods and products, which of course requires a change in a way of looking at not only the agricultural sector, but also for research using animals, and using animals for luxurious products.

The next social trends⁹ of our times is the virtualization of life in the western culture, which is connected with the informatization process and the growing number of different channels of communication. Some new factors are considered as important, which hasn't been enough regarded before like the body language, emotions and context. The majority of our contacts occur more and more basing on diverse channels, where the communication barriers result among other factors from the lacking common context, and lacking knowledge of the culture.

All of the mentioned social trends may result in the growing negativity of the concept of human nature, especially when it comes to the challenges from the environment: growing pollution, growing inequalities in the distribution of income, many different contacts to other cultures, religions and losing of the certainty about the one right way of functioning. This could lead to the growing separation, individualization, and virtualization of the world and human being. But on the other hand many researchers point to the negative outcomes of such tendencies and call for changes in the attitudes. One possibility is to explain those problems by the negative image of man – a destructive and an egoistic one, what doesn't promise much hope for any changes. The other is – by providing an image of man, which is a 'turning back to the sources' – discovering a nature of human being, which when lived according to it, gives a human being a possibility to conduct a happy life, which doesn't harm other. To overcome those difficulties it may

⁹ Trends which played a role for the actual development stage are described in: Horodecka (2008).

be important to create the concept of human nature, which has as well a normative function, as for instance homo sustinens from Bernd Siebenhüener has, which responds to the desires, and wishes of the society (Siebenhüener, 2000; B. Siebenhüener, 2001). The concept of 'homo sustinens' stresses the naturalness of human being and his/her genetic imprint, his/her cooperation and communication skills, his/her ability to learn and creativity as well as its ability to take the responsibility.

The actual changes in the concept of human nature

Changes in the concept of human nature result therefore from factors described above. Those changes reflected by other disciplines and in everyday-life impact as well on the changes of the image of man in the economics.

What are the major changes in understanding the person due to all the above mentioned factors? What are the effects of these major social changes resulting in the change of basic metaphors, growing interdisciplinary character of phenomena, the progress in the knowledge. Due to their activity, the demand for 'new concept' of human nature appears, as soon as the old one doesn't fulfill its functions (Horodecka, 2012a) and the new image emerges. Due to those changes, the 'image of man' is transformed, or replaced by a new one.

The economics as it was mentioned reflects in its concepts of human nature the major tendencies in social science and in the real environment (social trends). It adapts those concepts to the requirements which put on the concepts the economics. Each scientific discipline has its particular attitude to the observed phenomena which as well includes the way of perceiving a human being. What makes this science different from other is the diverse rule, which makes order in all phenomena within a particular science? Within social sciences this is a different concept of human nature, which makes the difference. For instance the psychology treats human being primarily as an individual, as a person whereas sociology is focused more on groups and societies as a primary phenomena. The economics focuses on the economic activity of human being – like working, buying, selling, exchanging. Each of those sciences has its central set of assumptions about human being. One of those sets of assumptions makes the dominating stream, even if there are other streams existing parallel. Psychology, for instance, bases on 4-5 different streams –basic paradigms: psychology of consciousness, phenomenological psychology, psychoanalysis, behavior-

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

ism, Gestalt psychology, cognitive science, constructivism. The other schools which differ strongly from the main stream are oft a part of the critics, for they unscientific character, like it is the case in psychoanalytical and humanistic psychology. The same case we have in economics where the central core is basing on the homo oeconomicus, and other especially heterodox concepts are criticized (see: Stępień & Szarzec, 2007) for instance for methodological reasons (inductive and not deductive character).

Those transformations can be seen either by tracing back the concept of 'homo oeconomicus' or by creating new concepts of man. In the first case we can ask, why concept of human nature, which existed in the economics in the pre-Smithian era changed and why such completely new concept like homo oeconomicus emerged. Especially these changes would be interesting, which mark the change of economic man between classical and neoclassical economics. In the second case we focus on watching the emerging concepts of human nature mainly in the heterodox economics.

Watching the transformation of the concept of human nature in the first case we can discover major factors contributing to the changes and formation of the new image of man. This may help to distinguish major forces of change.

During the life of Adam Smith in the end of 18th century, the economics was perceived as part of other sciences like philosophy. It means that the topics about economics were treated by philosophers, especially political philosophers, and by moral philosophers (Adam Smith was one moral philosopher).

What concept of human nature existed in the pre-Smith time and during his life? Answering this questions helps us to show how those factors described above contributed to the creation of a new concept of human nature – the homo oeconomicus, which origin development marked the beginning of classical economics and the mature state – the neoclassical (Stępień & Szarzec, 2007). During the Smith – era, a dominating concept was the Enlightened concept of human nature. In the debate about the economy there were some views on the role of human nature and his role in economic processes. The view that the world history depends not so much on the effort of individuals, but principally on some governors (the ideal was an absolutist enlightened governor), who is responsible for leading of the economics – trade politics and internal politics. All those insights has resulted in the mercantilist economic policy. The homo economicus as created by Adam Smith was an answer to the scientific explorations of a human nature, a reaction to the changes of worldview. Together with the change of

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

the worldview the person lost his/her central place in the world¹⁰. Human being became an element of the new puzzle – the world, a screw in the clock made by craftsmen. The world was like a clock made by the craftsmen God, who made it and after the creation withdrew himself from it. Therefore human being is lost in this great deterministic mechanism, and subordinated to the rules, which don't depend on his will and his action. The science and philosophy started to look for those rules, and other disciplines as well. In the natural science such an example was made by Newton, who created the basic of the physics. This trace was followed by other researches. The demand was as well in the economics. The dominating concept of human nature with the vision of man was requiring a new concept of human being, which would be more adequate to the current changes. In other words an image of man was required which is subordinated to the determinist rules, and deprive of power ruling individuals who became only screw in the world-clock, and subordinated to its rules. It was searched for rules, which could improve the functioning of the world. In order to achieve such an ideal, the role of individual had to be diminished, and deprived of their subject-character. Behavior of individuals was subordinated to the rule of pursuing own interest (or later own utility) and maximizing it with the help of rationality. The meaning of individual was reduced to a role of a part of a system, to which he/she was subordinated in a deterministic way. This was the way of looking on the economy by classic economists and its continuators and his followers (or better said: as classing economists, among them Adam Smith were interpreted by their ers¹¹). According to Smith the economy is working, because the effect of the whole depends on the rule, which is embedded into the human nature. The individual is subordinated to this rule. Smith wasn't appealing to norms, to which human being has to approach, because they are good, but he rather was looking for a law, by which he could describe the human behavior. It was a minimal program. But in his time the minimalist philosophy was a dominating stream, taking a distance from the metaphysics. The contemporary philosophy, especially the moral philosophy in those times can be characterized in a following way:

¹⁰ It meant the lost of the image of a person as created God alike, as microcosmos in a world view of Thomist philosophy.

¹¹ Klimczak, 2000 maintained that according to Smith such a egoistic motivated behavior is only the worst case, which was only taken into the analysis, to prove that even if all people behave in such a wrong way, the system will work. The average person acts diverse - according to some moral principles, and is lead by moral sentiments and empathy.

- It was dominated by the utilitarianism, putting away the metaphysical problems, and issues which demand for normative judgment, considering ethical behavior as a behavior, where the effect of our actions delivers us the maximal utility to us (extreme utilitarianism) or to the majority of people affected by such an action.
- Smith combined such two utilitarianist rules in one: the individual pursuing for maximization of its own utility maximizes as well the utility of all the people concerned by the action, and in consequence all society, and other countries as well (if the said country is engaged into trade)
- Smith was very far away of perceiving human being as cold egoist. His concept of man was as well subordinated to other laws (described in the 'Theory of Moral Sentiments', Smith, 2000)
- Those laws base on other rules, dealing with human activity. One of those rules is 'empathy, which says that human being can't be happy, if persons around him aren't. This means that the person would neglect behavior, which can harm others. On the same time the economic concept presented in 'Wealth of Nations...' (Smith, 2005) advised people to engage into those activities which we do best, and to neglect activities which we choose only in order to help others, but they don't count to our strengths. Doing that, what we can best, is according to "Wealth.." the most effective way of helping others because it leads to the welfare of the whole state. This economic rationality was later interpreted regardless considering negative effects of an individual activity harming others. The concept of human being created by Smith was a consequence of following changes:
 - a) Change of the worldview – the fate of the world doesn't depend any more on famous individuals but far more on the way of functioning of all screws in the system, which all follow a general rule
 - b) The growth of knowledge about a human being, a discovery that human being is guided by moral sentiments streaming for the maximization of his utility
 - c) Growing complexity of all economic processes, which contributed to the insight that there is no way of forecast of all factors influencing the economics, and so take the good decisions.
 - d) Other factors: the scientific embedding of the author (moral philosophy, England, birth of empiricism). Authorities which could influence the development of the idea: David Hume (1711-1776), John Locke (1632- 1704), Jeremy Bentham (1748-1832)

e) Experiences and observations made by the philosopher during birth of the industrial revolution

Those changes happening outside of the economics resulted in the changes in inside of the economics (even if there was no economics as a separate discipline, there were many reflections to the topics concerning economic activities of human science the ancient times). The old concept of human nature could afford the requirements of the capitalist economics, internationalization and industrialization. The separation of the economy of its local forms caused the demand for any theory, which would meet those requirements. Following those changes in the concept of human nature we can come to the conclusion that the factors responsible for the changes play great role in forming of changes in the concept of human nature.

Actual postulates for the modification of homo economicus have many different reasons, and we can differentiate following:

- The progress in the knowledge especially in behavioural psychology led to the discovery that human being is not guided by rational choices (see: Kahneman, 2001; Kahneman, 1973), but by some heuristics, which simplify the reality. The application of those heuristics leads to other results as those done by rational choices. In this way the assumption about maximization of utility can be modified. The term of suboptimal choice and bounded rationality replace such a typical rational choice. The mechanisms of choice applied in place of optimal choice are described by Kahneman. This is for instance the perspective theory, embedding mechanism (Kahneman, 2008)
- Due to the progress of in behavioral, cognitive schools of psychology and neuroscience it was proved that human being doesn't like risk. His/her dislike towards the risk is greater than we could expect by counting the expected value and the probability of achieving a profit (Kahneman & Tversky, 1979). This could be explained by the fact, that the negative and positive changes of income are experienced diversely. The same change in income when it is negative causes much greater 'pain' than the positive change cause 'happiness'. In other words: The utility loss by negative change of one unit of income is smaller than utility gain caused by positive change
- The development of evolutionary psychology (Wright, 2010; Buss, 2009) delivered some explanations towards the human behavior (without the necessity to enter into the subjective experiences of the human being, but remaining only by the sociological observation). This made clear that human motivation is not only oriented on survival or wealth

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

for self, but as well for other persons related to this person (having a part of its gen). According to one equation of William the tendency to show altruistic behavior is related proportionally to the level of relationship, the percentage of genetic code. It have been explored that the choices are determined by institutions, which gave basis to integration of institutional economics to neoclassical economics. As a consequence the new institutional economics emerged (Coase, 1998). Thanks to institutionalism the category of transactional costs is introduced, which cause that the individual doesn't choose the optimal choice¹². However in the new institutional economics, which accepts the homo oeconomicus, the basic motivation of human being for the maximization of utility hasn't changed, only a new category of costs is considered by the individual and social choices. A different use of the discovery of institutions made ecological, evolutionary, and feminist economics. They remained closer to the original thought of old institutionalists.

- The globalization influenced not only the change of world but is as well the next factor, which causes changes in the concept of human nature. Considering the cultural differences in the worldview has opened the eyes to the fact, that economic man is strong connected to the western civilization, but it can be totally unfamiliar to other cultures, which may neither accept it, nor understand.
- Some changes lead to only slight modifications of the homo oeconomicus (the first group). Other aren't yet adopted by the dominating paradigm or even their acceptance may cause the necessity of changing the paradigm. It's due to the fact, that they may possibly cause the necessity of changing the methodology or weren't compatible at all with major concepts of the orthodox economics (the second group).

The following changes caused a completion or slight modification to the existing concept of human nature, by the following dimensions:

- Institutional embedding of a person (institutional economics)
- Risk avoidance, tendency to taking rather suboptimal decisions (behavioral economics)
- Change of needs within time, considering of pre-and postproductive age in the decisions (a function of labour supply and a function for demand which are distributed through a whole life). This requires an institutional and historical analysis.

¹² This would be optimal if there haven't been transactional costs, which aren't maintained in the standard analysis

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

- Altruistic forms of behavior explained by egoistic motives and the growth of own utility and care in old age, children treated as an investment for old age (evolutionary, ecological, humanist, feminist economics)

To the other group count changes, which may lead to the necessity of changing the whole economics. This is because concepts developed here aren't compatible with the concepts developed within the standard economics.

- Streaming for the wellbeing not only per himself/herself but for other people (for instance: evolutionary economics, Hodgson, 2007; Dopfer, 2001 or humanist economics)
- Gender and cultural setting matters. The motives and behavior of people are perceived as being dependent from gender (feminist economics). The masculine homo economicus is completed by introducing of a female view on human being by considering the 'gender' perspective.
- The assumption that fulfilling of needs doesn't enlarge the wellbeing neither of the individual nor of the society. The individual in order to choose something what is good for him/her needs some insight. This insight is not understood as the full information, but as the knowledge about this, what is good for the individual and what not. This idea is close to what we refer to as a character of the person (for Tomer, 2011 it is as well the character). This is the case in the Buddhist and feminist economics, M.A. Lutz & Lux, 1979; M.A. Lutz & Lux, 1988; Schumacher, 1973
- The permanent growth in production isn't possible and required, because it leads to overgrowth of the economic system over the ecological one. The consequence of such a growth is the destruction of the ecological system, and therefore to the person, which depends on this system. The growth in production is often a consequence of enlarging some illusory needs (ecological economics, Daly & Farley, 2010, humanistic and Buddhist economics refers here to wants)

The characteristic of the concept of human nature in the contemporary heterodox economics as a result of social real changes and changes in knowledge

The changing environment resulting in changes in the concepts of human nature, is one of reasons for the criticism towards the homo economicus, who doesn't apply anymore to the environment it was meant for (time

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

of the industrial revolution, relative simple social structure etc.). An overview of major critical issues towards homo economicus can be found in Horodecka, 2014a. Those are for instance: (1) methodological issues, (2) lacking congruence with the empirics; (3) omitting some major factors determining human behavior; (5) short-sight of this approach; (6) lacking adequacy to the actual economic problems (crisis); (7) critics of the economics constructed basing on such an image of man.

The reasons discussed in the paper resulted in some changes of the concept of human nature in the contemporary economics, which are presented in the table below (Table 1). The next table (Table 2) presents the changes in the foundations of economics resulting of those changes in the concept of human nature. This stresses the necessity to deal with the changes of the images of man, in order to understand the contemporary and future economics.

Table 4 The concept of human nature in the contemporary heterodox economics as a result of social real changes and changes in knowledge

	Individual world	Social world and worldview
Behavioural	The critics of rationality – bounded rationality Emotional and rational nature of human being Behaviour: depends not on the subject of choice but on external factors as well (framing) and internal (personality, aversion to risk) Motivation: the role of emotions, often they aren't realized Meaning: this dimension is not discussed	The relation between people base on reciprocity There is no separate vision of world discussing relation to the nature and super-nature
Feminist	Two aspect of human being – feminine and masculine Behaviour: different behaviour associated with gender (man-women): rational-emotional, autonomous-dependent, egoistic-altruistic, rational choice – intuitive, preferences – needs Motivation: female and masculine motives – necessity to overcome this bias Sense: Integration of pluralism	The female and male world – complexity The economy should be part of the society and its values Social embedding of the individual The relation to the nature of human being is widely discussed, humans responsibility of the nature, impacting/reflecting the social structure
Humanist	Behavior: realization of higher needs (not: wants), pro-social behavior, altruistic Motivation: self-interest and social interest, lower and higher	The human is in the centre of the world, the world is a reflection of him/her The environment is changing (evolution of the society and culture), local community, and harmony within society (even if it

Conclusions

Actual changes in the society based on knowledge, exposed to the globalization processes accompanied by the changes in the knowledge and in philosophical views, which are answer to those trends leads to the necessity of changes in the concept of human nature. The paper discussed various reasons of the factors contributing to the changes of those models of man and effects they have on thinking about man in the economics.

The concept of man as it is in the neoclassical economics was developed in other context and doesn't apply to the actual changes. The critics of homo economicus relies on such aspects as: not regarding of actual empirical knowledge when it comes to human behaviour and motives, role and character of knowledge and information in the human life, character of the society, which is not a simple sum of individuals, but rather a net of processes, which are connected one with each other.

Therefore as result of all those social change, the concept of human nature in the contemporary most of all heterodox economics like evolutionary, ecological, humanistic, feminist and behavioural is a concept which is in relations to other people, in whose life play role not only egoistic motives but altruistic as well, and respecting the role of education and knowledge in the life of individual (especially when it comes to evolutionary economics), and cultural embedding of human being (in all mentioned heterodox direction in economics). The change of the goal of the economics, which is not more a positive one, but descriptive and normative as well, and connected to the environment. The focus lied on explaining the reasons and consequences of human economic behaviour, and solving of actual problems, by impacting as well on the institutions and change of attitudes. The enlarging of the field of the economics: not only the market counts, but

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

as well those outside of the market. The behaviour is not so much oriented on optimization but far more on satisfying. The new motives in the behaviour are considered (altruistic for instance) and the category of sense introduced. The economic system is considered as correlated with the natural, cultural, ethical one, and with religion and values. The methodology and methods changed their focus from orientation on models and prognosis, to description, explanations, understanding, experiments, discourse observation, historical, metaphors from other disciplines (like biological ones, evolutionistic).

Do those diverse factors contributing to changes of human nature result in one particular or diverse concepts of human nature. Probably the second answer is closer to the reality, although its not the scope of this paper to provide answer to this question. However many concepts of human nature share an ethical dimension. Therefore ethical concept of human nature or mentioned homo sustinens may be one possible answer to the requirements of our times. Such a concept corresponds with the requirement of the complexity and refers to all dimensions of human being. Ethical concept is not so narrow as religious one, and could be a common platform for many religions, it is a source of values and goals. The ethical approach is one which bases of virtues, self-control, orientation. The chance of adaptation of such a concept of human nature is growing, as soon as moral values and sensibility to questions of justice and responsibility for other and nature find more and more their way into the contemporary discourse¹³.

Non-profit Institutions' Funding Resources in the Time of Crisis: Market or Government?*

JEL Classification: *L31; L38*

Keywords: *non-profit institution; non-profit funding; economic crisis; system of national accounts; social services*

Abstract: According to the theory, there are reasons to assume that non-profit institutions (NPI) behave specifically, in the way that is significantly different from the behaviour typical for both for-profit and public service providers. We focus on the research question whether NPIs, in tough times of economic crisis. And such specific “under pressure” behaviour represents the key topic of this paper. Paper investigates NPIs’ reactions to the distinctive changes of the economic environment in the 2008 – 2013 when Czech NPIs were relatively strongly affected by the crisis, although this affection probably haven’t been as heavy as in some other European countries.

Non-profit institutions (NPI) are characterized by their multi-source funding when payments from end-consumers are relatively low. The most reliable data sources are Annual National Accounts and the Satellite Account of NPIs, presenting macroeconomic data. In this article we focus on structure of NPI funding resources changes in tough times of economic crisis.

* The research paper has been elaborated as one of the findings of specific research project research project “The Impact of Public Financing on the Structure of Resources and Production of Non-Profit Institutions”, supported by the Czech Science Foundation. Project identification GA14-06856S.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

The paper derives from the preliminary results of our extensive research project focused on the impact of public financing on the structure of resources and production of non-profit institutions. This project utilizes a quantitative representative questionnaire survey of non-profit institutions. In this article we focus on a specific area of public social services only.

The proposed paper seeks to prove that existing data sources do not capture the real/complex structure of NPI funding resources and will identify the shortcomings of the macroeconomic data and their scope.

Introduction

As stated in abstract, non-profit institutions (NPI) are generally characterized by their multi-source funding. There are numerous publications on this issue, including discussions on the public/private funding impact on the NPI production and behaviour. The examined question is to what extent the Czech official data capture the financial flows to NPI and their real structure. The first aim of this paper is to point to insufficient state of knowing in the context of the CR, especially concerning the structure of revenues of NPIs. After we explored these absent places in the realm of existing data on non-profit sector, we designed a project proposal for mapping the scope and structure of all resources of the Czech NPI. This proposal has been approved by the Czech Science Agency; we are in the second project year now.

Our paper briefly introduces the main objectives and research strategy of our survey-project which will allow us to test theories on the ratio of public and private revenue of NPIs. As the second goal of the paper, we are bringing some preliminary results of the survey concerning the Czech NPIs' behaviour in the times of economic crisis. Because of its specific nature, in particular because of the significant proportion of non-profit providers, the area of social services was selected.

Methodology of the research

We use a descriptive analysis of primary and secondary data to quantify the selected economic activity development and the financial flows to non-profit institution and to evaluate the development from 2008 till 2013.

We utilize secondary data from Satellite Account of Non-profit Institutions; we also use primary data in the form of preliminary findings from our representative survey of "The Impact of public financing on the structure of resources and production of NPIs" research.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

The most substantial source of secondary data is represented by the Satellite Account of Non-profit Institutions (hereinafter referred to as SANI). SANI serves as a source of macroeconomic data, including production and resources (revenues) of NPIs, as well as other macroeconomic aggregates. The Czech Republic is one of the few countries that also draw up a Satellite Account of NPIs as a part of their national accounting.

We use relevant data to create a more complete picture of the current state and development of NPIs and their resources in the Czech Republic, specifically in the field of social care.

As we describe before (Fonadová & Hyánek, 2015 pp. 377-384) at the most general level, we will examine whether resp. how the changes in the public sources revenues affect the functioning (and sustainability) of the Czech non-profit institutions. Part of this analysis is to identify the shortcomings of the macroeconomic statistics that provide the information on NPIs in the Czech Republic in order to prove the impact of the resource portfolio on the structure and character of production generated by NPIs.

Our research project is based on the survey method; thus focusing research has not been in this range implemented in the Czech context (representative sample size of 600 units). At the most general level, we examine whether resp. how the changes of the public sources revenues affect the functioning and sustainability of the Czech non-profit institutions.

Main research questions of our survey:

- Does the share of public resources in the total income of non-profit institutions indicated by them correspond to the level indicated by the available official data sources?
- Do the revenues from the central government institutions represent the most important income component of non-profit institutions?
- What is the significance of indirect and commercial resources in terms of total income of non-profit organizations?
- What type prevails in indirect sources of non-profit organizations: public or private?
- Does the internal organization structure of income change over time significantly?

Furthermore, we are interested in whether answers to these questions will vary:

- According to the organizational type (organizational size, age of the organization, industry...)?
- According to the total revenue (total budget) of the organization?

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

Firstly, we want to map how the amount and structure of public funds develops, while using the retrospective method of study (cf. de Vaus, 2001). We shall compare the data from 2013 and then retrospectively for the year 2008.

In this part of the research we will be able to determine:

- Whether and at what non-profit institutions report changes in the overall structure of income between the years?
- Is there a relationship between the changes in the revenue structure of the NPI and the amount of direct public revenue?

Through a standardized questionnaire there will be directly from the NPI collected information relating to the amount of their total income. Special attention will be devoted to the division on public and private sources, and also on income from the capital and from economic activity incl. non-financial sources of income.

Target file includes all non-profit organizations active on 31.12. 2013, which have already existed in 2008 (totally 105,522 units).

For the research purposes, we exclude from this set churches, public universities, hunting communities, political parties, professional associations, chambers of commerce and housing organizations; all of them represent organizational types on the edge of the nonprofit sector. This is valid for all the mentioned subjects except church organizations. Religious organizations are not included because they are given a special investigation.

After exclusion of specified categories of non-profit organizations, we get a basic set of about 80,000 units. Because of the high heterogeneity of non-profit organizations, we decided to use stratified random sampling.

We divide the basic set of non-profit institutions into 6 subgroups according to the ICNPO principles. From each of these groups, 75-100 units shall be randomly selected. Data from the first phase will be evaluated. In the second phase, we will focus on a set of non-profit institutions in which we find relevant direct public sources changes between 2008 and 2013 (decrease or, conversely, increase). The aim of this research is to find how the nonprofit production and strategies change as a result of direct public sources change.

In this paper we use preliminary findings derived from the analysis of 82 NPIs in the field of social services from representative survey.

State of Art

There are various theoretical definitions of private nonprofit sector organizations, such as the structural-operational definition (Salamon & Anheier, 1997), the definition based on the system of national accounts, definitions within SNA (United Nations, 2003), various functional definitions (Salamon & Anheier, 1997), specifications within the Pestoff welfare triangle (Pestoff, 1992), and the definition by means of a legal theory (Hurdik, 2003). Most of the definitions are negative ones, formed as authors attempt to perceive the private nonprofit sector alongside the public sector, the profit sector, and the household sector, or to assign definitional attributes to the private nonprofit sector.

Other terms are used in addition to private nonprofit sector, such as voluntary, civil, independent, nongovernmental, or third sector. The term selection depends on the discipline by which the phenomenon is analysed and the characteristics that are the most important for the respective author, and such terms are sometimes used simply to achieve any definition of the sector other than a negative one. Other non-theoretical concepts of nongovernmental nonprofit organisations are used in the Czech legislation (where these organisations are perceived as making no profit) and in the political sphere (where these organisations are perceived as nongovernmental organisations). The information capacity of various data sources with respect to individual definitions is connected with these concepts.

We've decided to use the definition of nonprofit institutions according to the standards of the European accounting system where nonprofit institutions are defined as "a legal or social entity created for the purpose of production of goods or services whose status does not permit them to be a source of income, profit or other financial gains for the units that establish, control or finance them. In practice, their productive activities are bound to generate either surpluses or deficits but any surpluses they happen to make cannot be appropriated by other institutional units" (ESA, 1995, p. 62).

NPI funding, and especially the public-private resource mix, belongs to the key issues in the non-profit sector focused research. In a way, the prominent position is occupied by examining the role and impact of public funding.

Of course, this is a topic that is historically deeply rooted in economic research; both positive and negative connotations of public financing interest and provoke economists at least since the 70s of the 20th century. So, maybe not completely new, but still topical. Moreover, in the environment

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

of post-communist countries Czech Republic, this area remains almost totally unexplored. It is surprising that in this environment we find no serious efforts to deepen the understanding of the structure of resources and their mutual substitution.

The most frequent issue in this context is the issue of the acceptance of commercial sources, especially in the situation of temporarily unstable public funding. Public finance can thus be seen as causing the phasing out the efforts of non-profit organizations to obtain additional private resources (crowding-out effect). And vice versa, we can expect positive impact of public finances (crowding-in) (Lecy & Van Slyke, 2012).

Space for alternative sources of income may generate public institutions themselves, simply by ceasing to subsidize certain types of services. According to Kerlin & Pollak, the nonprofit literature suggests that increases in public funding in earlier decades set the stage for the large impact of government cuts later on (Kerlin & Pollak, 2011).

In this context, strong connection of numerous non-profit subjects, and especially service providers, to any public budgets, represents the real problem. By the Salamon's estimate, social welfare cuts in the 1970s and 1980s resulted in the loss of US\$38 billion for nonprofits outside the health care field (Salamon, 1997). Other authors noted that hopes that private contributions would fill the gap were not realized as private contributions dropped from 26% of nonprofit revenue in 1977 to 18% in 1992 (Hodgkinson & Weitzman, 2001). One of the reasons, why the NPI reach for commercial sources is represented by constraints and cutbacks of public resources, typically in the tough times of economic crisis. Even here, however, there is not unanimous consensus among the authors.

Scholars have tried to prove that non-profit organizations relying on government funding turned to commercial activities to fill the gap left by cutbacks (Crimmins & Keil, 1983.; Eikenberry & Kluver, 2004). Salamon states, that between 1977 and 1989, nearly 40 % of the growth of social service organization income and 51 % of the growth of civic organization income came from fees and other commercial sources (Salamon, 1993). However, Foster and Bradach argue such statistics are taken out of context: "Fees and charges grew no faster in that 20-year period than other sources of revenue; they represented nearly half of the sector's total revenue in 1997, just as they had in 1977" (Foster & Bradach, 2005, p. 93).

There can be identified two research streams examining the phenomena of the public financing impact on the NPI behaviour. See Kerlin & Pollak: "Researchers who claim an increase in commercial revenue often use re-

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

source dependency theory to explain their findings. According to this theory, organizations depend on outside resources to operate and use “proactive strategies that can be pursued to deal with environmental constraints” (Kerlin & Pollak, 2011, p. 218). Thus, resource dependency proposes that non-profit losses in government grants and other traditional funding (like private giving, both individual and corporate) may prompt an increase in commercial revenue as a replacement.

This line of thinking considers commercial activities as an alternative that comes into play after the previous major financial source fails. But there is an alternative approach, which argues that more gradual rising costs to nonprofits and increased competition for private and government dollars may be the reason behind a continuing rise in commercial activity (Dees, 1998,; Weisbrod, 2004). Rather than resource dependency, this line of reasoning is more compatible with institutional theory which broadly examines the effect of an operating environment on an organization (Powell & DiMaggio, 2012).

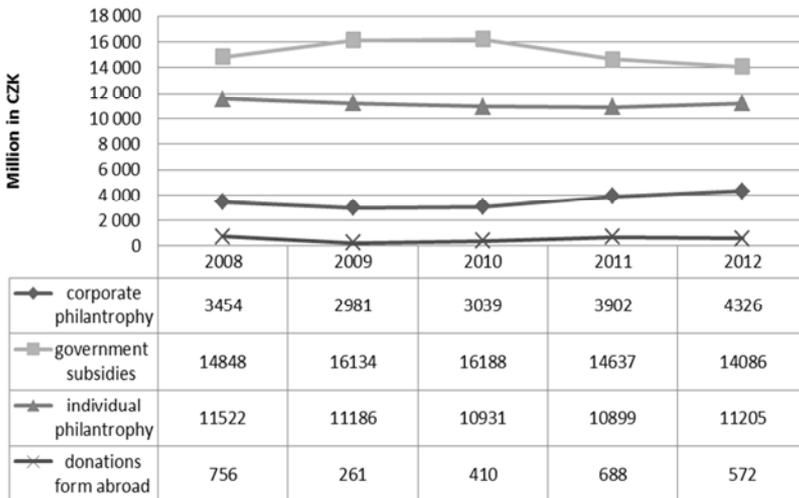

This means that for sustainability of the organization it is necessary to adapt to the institutional environment in which it operates. This is illustrated by the research of Flood, Fennel or Rao (Flood & Fennel, 1995,; Rao, 1998). They, in their conclusions, even speak of "mimetic and isomorphic" tactics adopted by nonprofit organizations. Of course, this line of thinking would mean that the tendency to commercial behavior is higher in countries with higher commercial environment. The increase in the commercial activities of non-profit organizations can then be understood as a kind of passive acceptance of the situation and response “to a number of outside pressures rather than a deliberate effort to subsidize declining revenue from discreet sources.” (Kerlin & Pollak, 2011, p. 701).

Here we’ve found a space for our research project which academic (theoretical) ambition is to test relevant theories in the Czech environment. We shall examine whether in the Czech context the public finance cutbacks really lead to increasing effort of obtaining commercial income or other behavioural changes.

NPI resources in the time of crises: Market or Government?

Figure 1 shows the evolution of donations and grants provided for NPI. After 2008, we witness a very slight decline in corporate and individual donations (including voluntary work). A significant decrease occurs in the level of foreign donations (both corporate and individual); it is logical, since many of these donor countries have experienced more serious impacts of the economic crisis than it was in the CR.

Figure 1. Public subsidies and various forms of donations in years 2008-2012 (in million CZK, 1 EUR = 27,7 CZK)

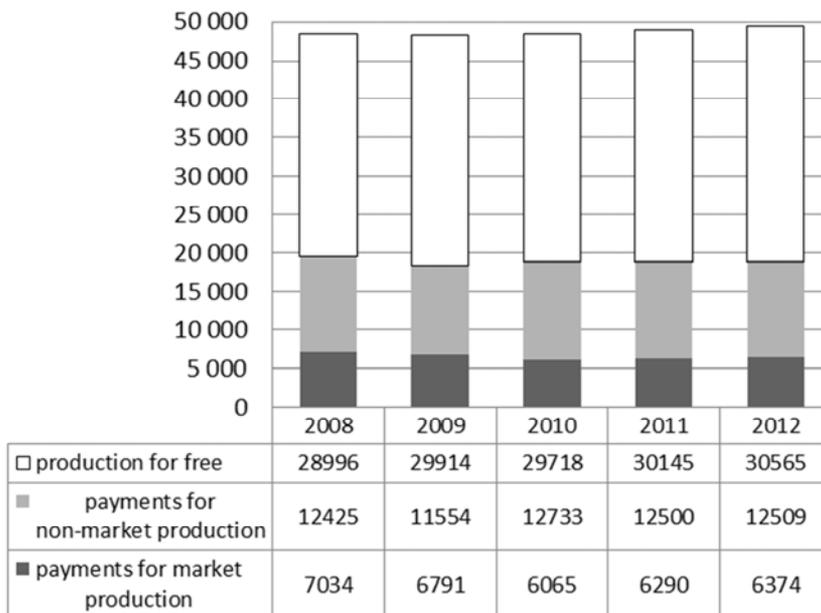

Source: own calculations based on Satellite Account of Non-profit Institutions (Czech Statistical Office, 2015).

In the case of public budgets subsidies, growth continues until 2010 (it took a while before the government responded by the cuts). The decline in these subsidies after 2010 returned to the level before the year 2008.

Production NPI behavior on the markets of goods and services is illustrated by the following graph.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

Figure 2. Structure of the NPI production in years 2008 – 2012 (in million CZK, 1 EUR = 27,7 CZK)

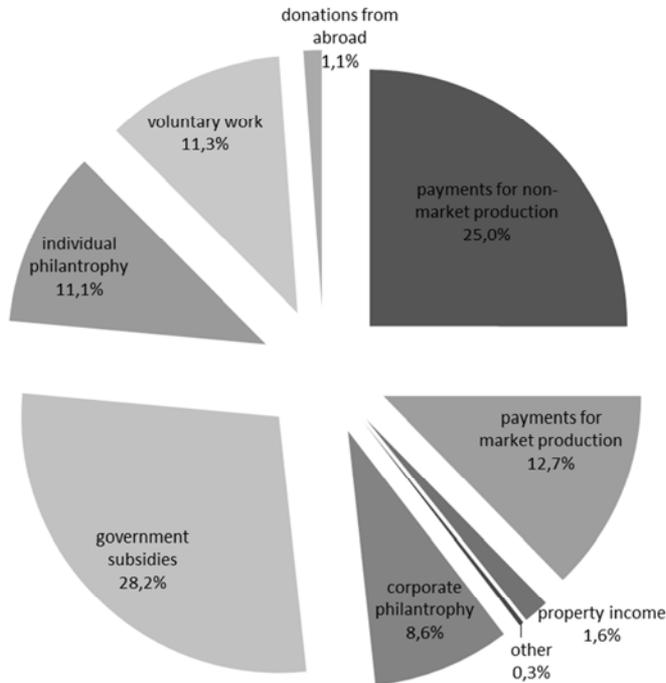

Source: own calculations based on Satellite Account of Non-profit Institutions (Czech Statistical Office, 2015).

In the evaluated period, free production for clients continues to increase. Until the 2010, we cannot talk about transferring the costs (in the form of increased prices) to consumers (see revenue from non-market production).

It is clear that the crisis did not move the nonprofit institutions in the direction of greater involvement in commercial activities. On the contrary, there is visible decline in the market production; the 2012 amount did not even reach the 2008 level.

Figure 3. Structure of NPI resources according to the Satellite Account of NPIs (share of resources in %)

Source: own calculations based on Satellite account of Non-profit Institutions (Czech Statistical Office, 2015).

Satellite Account of Non-profit Institutions shortcomings: case of social services

Czech macroeconomic data can show the structure of revenues and structure of production. But are we able to provide an explicit explanation of the impact of various funding resources on the overall production structure of Czech NPIs based on macroeconomics data? Do the existing data sources capture the real and complex structure of NPI resources and their mutual relationships?

We want to show shortcomings of National Account in the field of NPI resources at the representative sample of 82 social services NPI.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

Over 18% of NPI in the field of social services have no financial income. Their production is created by members and volunteers in rented buildings and bestowed or donated means of production.

One-third of the remaining 81% NPI, (which have also financial income) indicates high importance of indirect sources. In addition to the above mentioned indirect sources we can identify an extra tax relief, free accounting, legal and cleaning services, and advertising.

Macroeconomic statistics do not include indirect sources (except of voluntary work) and do not reflect their relevance to the NPI. The question remains, what could be the role of these resource in times of economic crisis.

Donations, in addition to the above mentioned corporate and individual donations, voluntary work and from foreign donors are also being obtained from the inside of the nonprofit sector. Nonprofit institutions obtain approximately 10% of total donations from other nonprofit institution. These are donations and grants from foundations, charities and religious organizations as well as funds provided by central or umbrella organizations.

In social services, payments for non-market production represent 34% of total financial income. According to our estimates, more than half of this 34% consists of contributions, which the government provides to clients in order to be able to purchase the social services. It is therefore an overrating of NPI income from the provision of goods and services and vice versa underestimation of revenues from public budgets.

Conclusions

In the article, we focused on two areas of concern. The first examined question was to what extent the Czech official data capture the financial flows to NPI and their real structure. After explaining the officially reported scope and structure of resources, we took the area of social services to show the “real” structure of resources. As important, but officially neglected, kind of resources we identified indirect sources that official statistics do not capture. These include tax allowances, tax exemptions from local and administrative fees, discount sales, loans or leasing of property, material equipping, services provided for symbolic or non-market prices or even for free, and the use of communication channels.

Similarly, we noted statistically unrecorded financial flows within the nonprofit sector, i.e. between different nonprofit institutions. The structure of NPI resources according SANI is distorted by contributions for client

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

from public finance to social services. Public finance spent on social services (in the form of contributions for client) appears in the budget of NPI as a sale of services. Because of its specific nature, in particular because of the significant proportion of non-profit providers, the area of social services was selected.

As the second goal of the paper, we have produced some preliminary results of the survey examining the Czech NPIs' behavior in the times of economic crisis. Our analysis led to the following conclusions: Statistical data and our research have showed that Czech NPI were not significantly affected by the economic crisis. The only exceptions can be found in a development of the volume of donations from abroad. A significant decrease occurs in the level of foreign donations, both corporate and individual. As we argue, it is only logical, since many of these donor countries have experienced more serious impacts of the economic crisis. It is also evident that non-profit institutions in the analyzed period did not incline to greater use of commercial sources.

Basically, the Czech non-profit institutions prefer a non-market solution of their potential financial insufficiency. Although a certain decline of public subsidies actually occurred, it has been delayed. That's probably also why the NPI managed to prepare for the potential lack of resources. Those potentially lost resources have been substituted by the private philanthropy, or other types of resources, but not by the commercialization of its activities.

In conclusion, this article brings new information not only about the structure of the real sources of the non-profit sector, but also about the behavior of non-profit entities. Of course, our conclusions are still only preliminary, and they will be subjected to other tests in the future. We believe that our work could serve as a basis for the work of other researchers, too.

**Allocating Tax Revenue to Sub-Central
Government Levels: Lessons from Germany and
Poland**

JEL Classification: *H2; H7*

Keywords: *apportionment of tax revenue, fiscal federalism, Germany, Poland*

Abstract: Tax sharing arrangements provide considerable financial resources to sub-central government levels. This statement is true both for unitary and federal states although tax revenue sharing mechanisms differ significantly across countries. The basic aim of this article is to compare the mechanisms adopted in Germany and in Poland. It assesses the degree of tax autonomy granted to sub-central government levels in the countries analysed, overviews the principles of apportionment of joint (shared) taxes and presents statistics on tax revenue composition of sub-central government levels.

Introduction

Over the last few decades the theory of fiscal federalism has attracted a lot of scientists' attention. According to this theory if there are no economies of scale than a decentralized pattern of public outputs reflecting differences in tastes across jurisdictions is welfare enhancing as compared to centralized outcome (Oates, 2008, p. 314). In order to cover expenditures related to the fulfillment of decentralized functions the sub-central government units require sufficient financial resources. In the case of a restricted

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

fiscal autonomy of these units the financing of their public tasks in a decentralized system is based mainly on a mechanism of transfers from the central (federal) government.

One of the main components of the fiscal autonomy of each government level is therefore taxing power. Governments may have three types of competences: in terms of tax legislation, in terms of tax revenue and in terms of tax administration. The decentralization of these competences may occur in various ways. For instance the central government may be responsible for tax legislation and tax administration, however tax revenue may be apportioned between different levels of government or in a more decentralized system local government may be entitled to set their own tax rates, to impose a surtax on a central (federal) tax liability or even to choose its own tax base, at least within the limits allowed for by a common tax administration system (Boadway, Shah, 2009, pp. 86-87).

The basic aim of this article is to compare the tax autonomy of sub-central government levels and tax sharing arrangements between different government levels in Germany and in Poland. Although Poland is classified as unitary state certain public responsibilities and competences are transferred to lower-levels of government. As a result Poland may be considered as more fiscally decentralized than some federal countries. Germany on the other hand is a cooperative federation, in which, for the majority of policy areas, the federal government sets the policy framework and the states are responsible for its implementation (Kedar, 2009, p. 172). There are significant differences in the scale of federal influence on sub-national governments between federal countries. Germany is amongst the countries where this scale is relatively large and the influence exercised on local governments is strong.

Methodology of the research

This article attempts to compare the taxing power of the public finance subsectors (different government levels) and the tax revenue sharing procedures in two European states which differ extensively with respect to the extent of decentralisation of the public finance sector, i.e. Germany and Poland. It distinguishes three categories of taxing power: power with respect to making tax law, power with respect to obtaining tax revenue and power with respect to managing tax collection (administering taxes). The degree of financial autonomy of a sub-central government unit depends

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

mostly on the two first categories. Therefore, they are the ones the article discusses the most thoroughly.

The methodology of this article is determined by the research topic and the research objectives. The scope of taxing power is specified in the legislation applicable in each of the two countries analysed. Hence, the first part of this article includes a legislative analysis of the regulations comprised in selected national acts. It focuses on provisions included in the Constitutions of both countries, acts specifying the sources of financing for local self-government units and defining principles according to which the tax revenues are shared. The relevant legislation is presented as of 31st December 2014. The first part of this article, also reviews Polish and foreign literature on the topic analysed, along with the publications of the German Federal Ministry of Finance (*Bundesministerium der Finanzen*).

The second part of this article contains the analysis of statistical data in regard to the tax and public revenue sources. This part includes the presentation of the structure of tax revenues by the public finance subsectors in Germany and Poland and a comparison of these structure in both countries. The share of different public finance subsector's in the joint tax revenues and in the total tax revenues of the public finance sector are calculated along with the percentage rate of the joint tax revenues in the total tax revenues and the share of the tax revenues in the total budgetary revenues for each subsector level. The statistical data used for these calculations come from the publications of the Supreme Audit Office (NIK) in Poland, the Central Statistical Office of Poland (GUS), the German Federal Ministry of Finance (*Bundesministerium der Finanzen*) and the Federal Statistical Office of Germany (*Statistisches Bundesamt Deutschland*).

**Tax autonomy of federal, state
and municipal governments in Germany**

In Germany one of the most important legal acts regulating the taxing powers of the Federation (*Bund*), the states (*Länder*) and the municipalities (*Gemeinden*) is the Constitution. The broadest competences to make taxation law are those of the federal government, which has the exclusive legislative power (*ausschließliche Gesetzgebung*) and concurrent legislative power (*konkurrierende Gesetzgebung*). Article 105 (1) of the German Constitution (*Grundgesetz vom 23 Mai 1949*) gives the Federation the exclusive power to legislate with respect to customs duties and fiscal monopolies. Taxes other than fiscal monopolies are regulated by the concurrent legisla-

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

tion. The Federation has the right to legislate taxes when the whole or the part of the revenue is allocated to the Federation or if the establishment of equal living conditions throughout the federal territory or the maintenance of legal or economic unity makes federal regulation necessary in the national interest. This means that with respect to other taxes, the states have the power to legislate as long as the Federation has not exercised its legislative power. In compliance with the provisions of Article 105 (2a) of the Constitution, the states have the power to legislate local taxes on consumption and expenditures as long as they are not substantially similar to taxes imposed by federal law. Moreover, the states have the power to specify the rates of the tax on the acquisition of immovable property (*Grunderwerbsteuer*). The municipalities (*Gemeinden*) do not have legislative powers, only the right to apply multipliers (*Hebesätze*) on the trade tax (*Gewerbesteuer*) and the real estate tax (*Grundsteuer*) within the limits specified by federal law. Legislation concerning other local taxes not regulated in federal acts of law is regulated in acts adopted by particular states.

In Germany there is a distinction between the vertical (*vertikale Steuerverteilung*) and horizontal system of tax revenue distribution (*horizontale Steuerverteilung*). The aim of the vertical system is to divide the revenues within the federation – amongst states, municipalities or unions of municipalities. It involves ascribing whole revenues from certain kinds of taxes to the federation, states and municipalities and proportional shares in the so-called shared (joint) taxes. The horizontal system of tax revenue distribution means the redistribution of these resources amongst units belonging to the same public finance subsector.

The rights with respect to obtaining tax revenues are regulated in Articles 106, 106a, 106b and 107 of the Constitution. On this basis the revenue from the following taxes is allocated to the Federation: excise on spirits (*Branntweinsteuer*), sparkling wines (*Schaumweinsteuer*), intermediate products (*Zwischenerzeugnissteuer*), sweet beverages containing alcohol, i.e. alkopops (*Alkopopsteuer*); tobacco tax (*Tabaksteuer*), energy tax (*Energiesteuer*), coffee tax (*Kaffeesteuer*), insurance tax (*Versicherungsteuer*), electricity tax (*Stromsteuer*), nuclear fuel tax (*Kernbrennstoffsteuer*), and air passenger tax (*Luftverkehrssteuer*). Apart from that the Federation receives tax revenues from the road haulage tax (*Straßengüterverkehrssteuer*), the motor vehicle tax (*Kraftfahrzeugsteuer*), and other kinds of taxes on transactions related to motorised means of transport, one-time capital and compensation levies, subsidiary levies on personal and corporate income taxes, e.g. the solidarity surcharge (*Solidaritätszuschlag*), and levies im-

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

posed due to the membership in the European Union. The next group of taxes are those which are allocated entirely to the states; these include: the inheritance and gift tax (*Erbschaftsteuer/Schenkungssteuer*), tax on the acquisition of immovable property (*Gründerwerbsteuer*), fire protection tax (*Feuerschutzsteuer*), betting and lottery tax (*Rennwett- und Lotteriesteuer*), beer tax (*Biersteuer*) and gaming casinos levy (*Abgabe von Spielbanken*). As far as municipalities and unions are concerned, they receive tax revenues from the following taxes: the real estate tax (*Grundsteuer*), dog tax (*Hundesteuer*), beverage tax (*Getränkesteuer*), hunting and fishing tax (*Jagd- und Fischereisteuer*), trade tax (*Gewerbesteuer*), secondary residence tax (*Zweitwohnungsteuer*), entertainment tax (*Vergnügungssteuer*), licensing tax on the sale of beverages (*Schankerlaubnissteuer*), and packaging tax (*Verpackungssteuer*).

The most important taxes in the German tax system are shared taxes. Revenues from these taxes are divided between the Federation, the states and the municipalities. They include: the assessed income tax (*veranlagte Einkommensteuer*), wage withholding tax (*Lohnsteuer*), withholding tax on capital gains (*Abgeltungssteuer*), other withheld income taxes (*nicht veranlagte Steuern von Ertrag*), corporate income tax (*Körperschaftsteuer*), and value added tax (*Umsatzsteuer*). The statutory share of the Federation, the states and municipalities in the revenue from the shared taxes is presented in Table 1.

Table 4. Statutory share of Federation, states and municipalities in revenues from shared taxes in Germany

Type of tax	Share in %		
	Federation (<i>Bund</i>)	States (<i>Länder</i>)	Municipalities (<i>Gemeiden</i>)
Assessed income tax; Wage withholding tax	42.50	42.50	15.00
Withholding tax on capital gains	44.00	44.00	12.00
Other withheld income taxes	50.00	50.00	–
Corporate income tax	50.00	50.00	–
Value added tax	53.47	44.53	2.00

Competences with respect to tax administration are regulated by Article 108 of the Constitution and the Tax Administration Act (*Finanzverwaltungsgesetz vom 30. August 1971*). The law grants the federal government authorities competences to administer duties, fiscal monopolies and consumption taxes where the principles concerning their collection are speci-

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

fied in federal acts; these levies include VAT on imported goods and other taxes on transactions related to motorised means of transport, collected since 1st July 2009, as well as taxes collected in relation to the European Communities.

The remaining taxes are administered by the fiscal authorities of the states. The only exceptions are taxes where the revenue is allocated entirely or partially to the Federation. In compliance with Article 108 (3) of the Constitution these levies are administered by the states on behalf of the Federation. The states are free to choose the organisation of their administration and the only rule to follow when organising the administration is the principle of uniform taxation in compliance with the law (Ulbricht, 2008, p. 198).

The statutory share in revenues from the shared taxes allocated to the states is divided amongst them in accordance with a statutory key. With respect to income taxes the principle of residence is taken into account. Thus, a state is given the income tax paid by a taxpayer if the taxpayer lives in this state or – in the case of corporations – if the corporation's management board is located in this state (§ 1 (1) *Zerlegungsgesetz vom 6. August 1998*). As a result the distribution of the revenues depends on the amount of tax revenues generated by a given state. In the case of the distribution of revenues from value added tax, the rules are different: as much as 75% of the revenue from VAT to which the states are entitled is distributed on the basis of the number of inhabitants of the relevant states. The remaining 25% is a subsidy which is divided depending on the so-called fiscal performance index (*Steuerkraft*). Calculating the fiscal performance index involves taking into account the share of a particular state in the revenues from the assessed income tax, wage withholding tax, withholding tax on capital gains, other withheld income taxes, corporate income tax, trade tax and the revenues of these states from the remaining taxes per inhabitant. A state is entitled to a subsidy if this index is lower than the average calculated for all the states (§ 2 (1) *Finanzausgleichgesetz vom 20. Dezember 2001*).

Both the Federation and the states are entitled to a share in the trade tax. Municipalities are obliged to transfer a share of the tax revenues from that tax to the Federation and the states under Article 106 (6) of the Constitution. The amount to be transferred depends on the local multipliers imposed on the trade tax and the location of a particular municipality (whether it is located in a new or an old state). Moreover, since 1st July 2009, the states

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

participate in the revenues from the motor vehicle tax collected by Federation.

The share of a particular municipality in the revenue from income taxes depends on the taxable income and the tax paid by its inhabitants in a statutorily defined year. In the calculation of the revenues from the aforementioned taxes received by a municipality and in order to equalise the differences between municipalities whose inhabitants generate high income and those whose inhabitants generate low income in the case of each taxpayer only income up to a certain level is taken into account. The amount used in the calculation is 35,000 euros, in the case of individual tax settlement, and 70,000 euros, in the case of joint tax declaration (*Gemeindeanteil* 2014, p. 21).

The apportionment of the revenues from value added tax is extremely complicated due to several amendments made in 1998 (implementation of the compensation for the abolition of the trade tax on business capital that accrued to the municipalities) and in 2007 (increase of the standard VAT rate) (Englisch, Tappe, 2011, p. 285). When distributing the municipalities share in the revenues from value added tax amongst particular municipalities, the following elements are taken into account (in statutorily regulated proportions): the revenue from the trade tax, the number of employed obliged to pay insurance contributions, the amount of wages paid from which social insurance contributions must be made.

**Local tax authority and the tax revenue
sharing mechanism in Poland**

Unlike in Germany, in Poland the provisions of the Constitution do not regulate in detail the scope of taxing power of public finance subsectors (the Constitution of the Republic of Poland of 2 April 1997; *Konstytucja Rzeczypospolitej Polskiej z dnia 2 kwietnia 1997 roku*). Article 16(2) of the Constitution includes, however, the principle of independence of local self-governments. In compliance with this principle local self-government units participate in exercising public power and are obliged to perform public tasks assigned to them on its own behalf and responsibility. The execution of these tasks is possible thanks to local self-governments' share in public revenue, including, according to Article 167(2) of the Constitution, their own revenues, general subsidies and specific grants designated from the state budget.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

In Poland competences in the field of tax law-making are vested in the central government. The authority equipped with the power to enact tax law is Parliament. In principle the units of local self-government and their organs do not have the power to make tax law. However under Article 168 of the Constitution the units of local self-government have the right to establish the rates of local taxes and charges in compliance with statutory regulated rules. As far as municipalities (*gminy*) are concerned their competences with respect to tax law are implemented primarily by means of tax resolutions adopted by the municipal council (Popławski, 2009, p. 40).

The provisions of the Local Taxes and Fees Act of 12 January 1991 (*Ustawa z dnia 12 stycznia 1991 roku*) entitle the municipal councils to determine the rates of real estate tax, motor vehicle tax, market duty, visitor's and resort duties, as well as the duty on dog owners. The rates may not exceed the upper limits specified in the statute. Municipal councils also have the right to determine the rules for the collection and time of payment of these taxes and duties, and to introduce tax deductions and exemptions. Moreover under Article 6(3) of the Farm Tax Act of 15 November 1984 (*Ustawa z dnia z dnia 15 listopada 1984 roku*), municipal councils may influence the amount of the farm tax by reducing the purchase prices of rye taken as a basis for calculating the tax, and – on the basis of Article 4(5) of the Forest Tax Act – influence the amount of forest tax by reducing the average selling price of wood taken as the basis for calculating the forest tax (the Act of 30 October 2002; *Ustawa z dnia 30 października 2002 roku*).

Most of the taxes in Poland constitute the source of revenue for the state budget. They include: value added tax, the excise duty on the following products: alcoholic beverages, tobacco products, energy and electricity, passenger cars, the gambling tax, flat-rate tax on registered income, tax on sale of securities, flat-rate tax on income of the clergy and the mineral extraction tax. The Polish tax system does not allow for any taxes which would constitute revenues of the districts (counties; *powiaty*) or regions (provinces; *województwa samorządowe*). The sources of revenue for municipalities, on the other hand, are such taxes as: the real estate tax, farm tax, forest tax, motor vehicle tax, gift and inheritance tax, tax on civil law transactions and the fixed sum tax on the business activity of individuals (so called tax card assessment). Apart from that the following duties also contribute to the municipalities' budgets: the stamp duty, market duty, visitor's and resort duty, duty on dog owners and a share in the mineral exploitation duty.

Table 2. Statutory share of public finance subsectors in revenues from shared taxes in Poland

Type of tax	Year	Share in %			
		State (<i>budżet państwa</i>)	Regions (<i>województwa</i>)	Districts (<i>powiaty</i>)	Municipalities (<i>gminy</i>)
Personal income tax	1999-2003	69.90	1.50	1.00	27.60
	2004	50.64	1.60	8.42	39.34*
	since 2005	48.81	1.60	10.25	39.34*
Corporate income tax	1999-2003	94.50	0.50	0.00	5.00
	2004-2007	75.99	15.90	1.40	6.71
	2008-2009	77.89	14.00	1.40	6.71
	since 2010	77.14	14.75	1.40	6.71

* The share of the municipalities in the revenues from personal income tax decreases by the number of percentage points equal to the product of 3.81 of the percentage point of the index calculated for the whole country. The index rate is established by dividing the number of inhabitants admitted to residential homes before 1st January 2004, as of 30th June of the base year, by the number of inhabitants admitted by 1st January 2004, as of 31st December 2003. The participation share of municipalities in the revenues from the personal income tax was 35.72% in 2004, in 2005 – 35.61%, in 2006 – 35.95%, in 2007 – 36.22%, in 2008 – 36.49%, in 2009 – 36.72%, in 2010 – 36.94%, in 2011 – 37.12%, in 2012 – 37.26%, in 2013 – 37.42%, in 2014 – 37.53.

Source: Jastrzębska (2012, p. 114).

Local taxes are administered by local authorities: the village head, the mayor or the president. The only exceptions are: the gift and inheritance tax, the tax on civil law transactions and the fixed sum tax on business activity of individuals, which constitute the source of revenue for municipalities but are administered by the central government authorities, i.e. the heads of tax offices. All other taxes are administered centrally.

In Poland personal and corporate income taxes are shared taxes, i.e. revenues from them are distributed amongst the state, regions, districts and municipalities. The share of public finance subsectors in revenue from these taxes is presented in Table 2.

In compliance with Article 9 of the Act of 13th November 2003 on the Revenues of Local Self-Government Units (*Ustawa z dnia 13 listopada 2003 roku*), the amount of a municipality's share in the revenue from personal income tax is calculated by multiplying the total amount of the revenue from this tax by 0.3934 and an index equal to the share due in the year preceding the base year of the personal income tax from persons resident in a given municipality, as the total amount of the tax to be paid by all taxpayers in the same year. In the case of a district the amount of its share in the

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

revenue from personal income tax is calculated by multiplying the total amount of the revenues from personal income tax by 0.1025 and an index equal to the share of the personal income tax due in the year preceding the base year of the personal income tax from persons resident in a given district, as the total amount of the tax to be paid in the same year. In the case of regions, on the other hand – this share is calculated by multiplying the total amount of the revenue from this tax by 0.0160 and an index equal to the share of the personal income tax from persons resident in a given region due in the year preceding the base year, as the total amount of the tax to be paid in the same year. These indices are established on the basis of statistics from tax returns submitted on the amount of income and annual tax calculations made by taxpayers as of 15th September of the base year.

The amounts of shares of regions, districts and municipalities in the revenue from corporate income tax depends on the number of taxpayers having registered offices or facilities in their territories. If a corporate income taxpayer has a facility on the territory of a local self-government unit other than the one where its registered office is located, part of the revenues from the share in the revenue from this tax is transferred to the budget of the local self-government unit in which this facility operates, proportionally to the number of people employed there under a contract of employment. In the case of a corporate income taxpayer conducting business through a foreign facility located in the Republic of Poland part of the revenue from the share in the revenue from this tax is transferred to the budget of the local self-government unit where the employers of this taxpayer or of his foreign facility perform work under a contract of employment, proportionally to the number of people employed by him or this foreign facility located in the Republic of Poland.

**Tax revenue assignment in Germany and Poland
in the years 2009-2013**

Both in Germany and in Poland taxes constitute an important source of the public revenue. However their significance varies considerably for different public finance subsectors. In Germany the share of tax revenue in the total revenue of the Federation and the states in 2009-2013 was similar (Table 5). The basic source of tax revenue for both the Federation and the states are shared taxes, which constitute about 74% of the total tax revenue of the public finance sector (without taking into account the subsector of social insurance) and about 80% of the tax revenue both for the Federation

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

and the states. From Table 3 it can be concluded that the dominant source of revenue for the Federation is the value added tax. This is related not only to its collection efficiency but also to a considerable statutory share of the Federation in the revenue from this tax. A significant source of revenue for the Federation are also excise duties, the revenue from which account for over 20% of its tax revenue. The most efficient are the excise duties imposed on energy and tobacco products.

The tax revenue of the Federation are reduced by amounts transferred to the budgets of other entities of the public finance sector and the budget of the European Union. The amounts deducted from these revenues include their own resources of the EU – both VAT- and GNI-based, as well as supplementary federal grants (Bundesergänzungszuweisungen). Moreover the Federation gives part of its revenue from the taxation of mineral oil to the states under Article 5 of the Regionalization Act (Regionalisierungsgesetz vom 27. Dezember 1993). These resources are used to finance inter alia railway transport. The federal budget also pays the states a percentage of revenue from the motor vehicle tax. The states' share in the revenue from shared taxes and tax revenue in total is slightly lower than the share of the Federation (from 3 to 5 percentage points). The states obtain their own tax revenues mainly from the tax on the acquisition of immovable property, inheritance and gift tax and the excise duty on beer. However the largest revenue of the states comes from their share in value added tax.

Table 3. Tax revenue of the Federation, states and municipalities in Germany in the years 2009-2013 (in million EUR)

Public finance subsectors	TAX	2009	2010	2011	2012	2013
Federation	Assessed income tax	11 233	13 251	13 589	15 837	17 969
	Wage withholding tax	57 445	54 359	59 393	63 352	67 234

In the case of municipalities both the proportion of the revenue from the shared taxes in the total tax revenue and of the total tax revenue in the total revenues is lower than in the case of the Federation and the states. The share of municipalities in the revenues from the shared taxes is insignificant and does not exceed 8%. The budgets of municipalities are supplied mostly by subsidies and grants. The largest tax revenue sources of municipalities are their share in the wage withholding tax and the trade tax.

Source: Data from Table 3.

In Poland the share of tax revenue in public revenue is relatively high in the case of the state budget (Table 6). The most important sources of tax revenue are value added tax and the excise tax, the revenues from which account for about 73% of all the tax revenue of the state budget.

The percentage of shared taxes in this budget is definitely lower than in Germany. It must be also emphasized that, unlike Germany, in Poland the value added tax is not a shared tax. At the same time the proportion of income taxes, which are shared in the tax revenue of Federation in Germany was, in the years 2009-2013, 12.5 to 18.0 percentage points higher than the proportion of income taxes in the tax revenue of the state budget in Poland; one of the reasons is the higher collection efficiency of German income taxes. The regional level of local self-government in Poland does not have any tax revenue; it has a share of the shared taxes but they are insignificant. In the case of districts, which also do not have their own tax revenue, the proportion of revenue from the shared taxes in the total is even lower.

Source: Data from Table 4.

Municipalities and cities with district rights have their own tax revenue, which include also shares in shared taxes. It must be noted that the share of municipalities and cities with district rights in revenues from personal income tax is relatively high. As a result municipalities in Poland are entitled to a higher share in revenue from shared taxes than in Germany. The situation is different in the case of the share of particular levels of the public finance sector in tax revenue. In the case of German municipalities this share is higher than in Poland. This is a result of a higher collection efficiency of local taxes in Germany. One of the most important sources of tax revenue for German municipalities is the trade tax. The most efficient source of tax revenues for Polish municipalities is the real estate tax.

Conclusions

Taxing powers of German and Polish sub-central government units differ considerably. These differences are especially visible when comparing tax competences of regions and districts in Poland and the states in Germany. It must be added that the sources of revenue and their structure are adjusted to a greater or lesser extent to the need for public resources and to the public tasks performed. Due to systemic differences between the two countries the tasks of Polish regions and districts are different from those of German states.

States in Germany have relatively broad taxing powers. The Constitution provides them with the power to legislate with regard to local taxes on consumption and expenditures so long and insofar as such taxes are not substantially similar to taxes regulated by federal law. German states receive revenue from selected wealth and sales taxes. Moreover the Federation and the states have a similar level of revenue from shared taxes, which results in a comparative level of their shares in tax revenue. In Poland, regions and districts have no legislative powers with respect to tax law. They do not generate any of their own tax revenue but do participate in the revenue from the shared taxes. However their share in tax revenue that include only the revenue from shared taxes is insignificant. Therefore, their most basic sources of funding are general subsidies and specific grants.

The taxing power of municipalities is significantly restricted both in Germany and in Poland. The legislative powers of municipalities with respect to tax law are limited to deciding the rates of some local taxes (only within statutory restrictions). Municipalities have no power to independently impose taxes and shape the elements of the overall tax design. German municipalities are entitled to a lower share in the revenue from shared taxes than in Poland but their share in the tax revenue of the public finance sector is still higher. A significant part of the tax revenue of municipalities in Germany comes from a relatively efficient trade tax.

A comprehensive evaluation of the scope of independence of local self-government units in both countries would require the taking into account of not only the level and structure of their tax revenue but also their revenue from other sources and the level and structure of their expenditure, taking into account tasks performed at various levels of the public finance sector.

**Eco-innovations in the Business Practice of the
Companies Traded on the Warsaw Stock
Exchange – an Overview of Selected Results**

JEL Classification: *O13; O30; O32*

Keywords: *Eco-innovation; green economy; sustainability; environment*

Abstract: The main objective of our study is to identify and assess chosen aspects of eco-innovativeness of the companies listed within the indices: WIG Energy, WIG Oil & Gas, WIG Basic Materials on the Warsaw Stock Exchange. The scope of this analysis encompasses selected results which facilitate achieving environmental benefits. Our investigation, however, does not cover the expenditure on eco-innovative activities as well as the instruments measuring the influence of eco-innovation. The analysis of the investigated dilemma was based mainly on two research methods, namely survey analysis and digital and documentary source analysis. The results indicate a relatively high eco-innovativeness of the companies in terms of organizational and marketing activities, and low in product and services eco-innovativeness.

Introduction

Current sustainability research defines eco-innovation as a global challenge. The transition to Green Economy, based on the integration of economic, social and environmental factors, will depend on eco-innovation. According to the European rating of eco-innovation in 2013 (defined within

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

Eco-Innovation Observatory - EIO), Poland is considered to be an outsider among EU countries. The research by Institute for Structural Research (ISR) attributes this situation to a relatively low awareness of eco-innovation, underestimation of cooperation in the process of eco-innovation and lack of knowledge regarding the implementation of eco-innovation.

The aim of our study is preliminary identification and evolution of eco-innovative activities (environmentally-friendly) in the business practice of the companies listed in the Warsaw Stock Exchange in the following indices: WIG Energy, WIG Oil & Gas, WIG Basic Materials, based on the methodology developed in the framework of international projects (OECD, 2005, MEI Project, 2007).

Some countries do lag behind, some do not, in terms of the development and introduction of eco-innovations. Often, the leadership in eco-innovations is accompanied by a leadership in environmental policy. Previous studies focused on examining the impact of environmental performance on the value of an enterprise, and researchers used various methods to study the effect of environmental performance on its value.

Most OECD countries have developed or improved national strategies to support eco-innovations. In the UE there are several studies analyzing and promoting eco-innovations, i.e. the EU Commission study: *Promoting Innovative Business Models with Environmental Benefits* (2008) which recommends a greater action to spread such business models which would estimate the potentials for economic and environmental benefits, and the ways in which the models can be promoted, and the *Environmental Technology Action Plan* (ETAP) which had invited EU members to develop eco-innovation roadmaps. "In the United States, environmental technologies are seen as a promising means of improving environmental conditions and are being promoted through various public-private partnership programmes" (OECD, 2008). Not only European countries or the United States, but also Asian countries promote eco – innovation, i.e. in Taiwan regulators, scholars, and two stock exchanges - Taiwan Stock Exchange Corporation (TSEC) and GreTai Securities Market (GTSM) – get involved in research projects (2010) and lawmaking to encourage or regulate firms to behave in socially (and environmentally) responsible ways.

Poland is at an early stage of developing environmental consciousness, however, the study on the impact of eco-innovations on the value of the company has not been carried out yet. By Eco-Innovation Observatory (EIO), Poland took second place significantly below the EU average (45 out of 100). For this reason the development and implementation of eco-

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

innovative technologies are now supported by the key national and regional strategies. Still, some of the scholars conducted a research devoted to the effectiveness of SR investment (Socially Responsible) in which also environmental aspects were taken into account (Janik & Bartkowiak, 2013, pp. 25-33), (Janik, 2014, pp.25-36). There are also several research made about ecological activity in financial institutions (Dziawgo, 2014, pp. 9-24).

The concept of eco - innovation consists of two of separate parts: the ecology and innovation. The ecology according to the definition by Cary Institute of Ecosystem Studies is: “the scientific study of the processes influencing the distribution and abundance of organisms, the interactions among organisms, and the interactions between organisms and the transformation and flux of energy and matter” (CIES, 2015). While the innovation defined according to Oslo Manual (OECD, 2005) “is the implementation of a new or significantly improved product (good or service), or process, a new marketing method, or a new organizational method in business practice”. Eco-innovation can be generally defined as innovation that result in a reduction of environmental impact, no matter whether or not that effect is intended. Below are presented the main definitions of eco-innovation in chronological order.

Table 5. Definition of eco-innovation

Author	Year	Definition
Fussel and James	1996	„New products and processes which provide customer and business value but significantly decrease environmental policy”
Klemmer	1999	“Techno-economic, organizational, social and institutional changes to an improved quality of the environment”
Driessen and Hillebrand	2002	Green innovation “does not have to be developed with the goal of reducing the environmental burden” but it “does however, yield significant environmental benefits”
OECD (Oslo Manual)	2005	“is the implementation of a new or significantly improved product (good or service), or process, a new marketing method, or a new organizational method in business practice”.
Kemp and Pearson in MEI Report	2007	“Eco-innovation is the production, assimilation or exploitation of a product, production process, service or management or business method that is novel to the organization (developing or adopting it) and which results, throughout its life

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

		cycle, in a reduction of environmental risk, pollution and other negative impacts of resources use (including energy use) compared to relevant alternatives”.
Huppès, G. et al. in ECODRIVE Report	2008	Defined eco-innovation “as the combined improvement of economic and environmental performance of society”.
Oltra and Saint Jean	2009	“Innovations that consist of new or modified processes, practices, systems and products which benefit the environment and so contribute to environmental sustainability”
Eco Innovation Observatory (EIO)	2011	“Eco-innovation is any innovation that reduces the use of natural resources and decreases the release of harmful substances across the whole life-cycle”.

Source: Bitat, (2013) pp. 4-5; Driessen, & Hillebrand, (2002); EIO, (2011); Fussler, & James, (1996); Huppès, G. et al. (2008); OECD/Eurostat, (Oslo Manual), (2005); Oltra & Saint Jean, (2009).

Based on the analysis of literature (by OECD; Eurostat, 2005; Reid & Miedzinski, 2008), eco-innovation can be considered in the context of the three planes: target, mechanism, impact.

- Target (according to *Oslo Manual*, the target of an eco-innovation can be categorized under: products, processes, marketing methods, organizations, institutions).
- Mechanism (relates to the method by which the change in the eco-innovation target takes place).
- Impact (refers to the eco-innovation’s effect on environmental conditions across its live cycle).

The introductory paragraph outlines clearly state the objectives and motivation for writing the paper. The introduction should provide a context for the discussion in the body of the paper.

Methodology of the research

The research on the eco-innovativeness of companies is a relatively young discipline and the methodology used currently to measure eco-innovativeness constitute mostly the achievements of the last years. The first decade of 21th century brought along several huge international research projects on the area indicated above. One of their important result was the definition of clear typologies of eco-innovation and of adequate

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

methods of their measurement. In the subsequent part of this article, we will concentrate on the methodology of eco-innovation measurement in order to prepare a research tool facilitating the implementation of a planned empirical research.

Though current theoretical achievements in the area of eco-innovations took place mostly due to the past decade, still the methodological basis for eco-innovations and their measurement was set up much earlier. At the beginning of the 90s of 20th c. Acs and Audretsch noticed that eco-innovation might be assessed on the basis of the three following measuring tools: *input measures*, *intermediate output measures* and *direct output measures* (Acs & Audretsch, 1993, p.10). Within input measures they enumerated expenditure on research and development activities, personnel employed in R&D as well as expenditure on innovation. Intermediate output measures included the number of patents and academic publications concerning company's eco-innovativeness etc. whereas direct output measures encompassed the number of innovations, the description of individual innovations, the data about the sale of new products etc.

The above mentioned criteria of measurement were modified and developed with time as well as became more specified. To the above mentioned measures, *indirect impact measures* were added. They were identified by aggregate data concerning changes in the effectiveness of using the resources and productivity (based on *decomposition analysis*). Eco-efficiency is defined as „[...] the delivery of competitively-priced goods and services that satisfy human needs and bring quality of live, while progressively reducing ecological impacts and resource intensity throughout the lifecycle to a level at least in line with the earth's estimated carrying capacity" (WBCSD, 2000, p. 9). So, it is measured at the level of a product and service. Among the main ingredients of eco-efficiency the following are enumerated (Arundel & Kemp, 2009, p. 23):

- quantity of product produced (or sold), net sales, etc, as output indicators;
- energy consumption, from renewable sources and non-renewables;
- water consumption;
- greenhouse gas emissions (GHG);
- other emissions to air;
- total waste.

Current research concerning eco-innovation seem to concentrate on effects measures. It may be well shown by the classification of eco-innovation according to the MEI Project, which is based on the criteria of

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

innovation purpose. In this case, it is clearly visible that the attention is put on direct effects of eco-innovation process (see Table 1), however, two measures are combined together (which previously have never been joined), i.e. the measures of innovativeness and environmental ones. Among these measuring innovativeness we can find: the number of organizational innovations environmentally-friendly, the number of produced (and 'service') innovations beneficial to the environment and the number green system innovations, whereas the measure of environmental benefits was based on individual technologies used to control pollution and noise, managing waste, limiting water use, environmental monitoring etc.

Table 6. Eco-innovation measures according to MEI Project

Main measures	Detailed measures
Innovation measures	
Organizational innovation	<ul style="list-style-type: none"> – pollution preventions schemes – environmental management and auditing systems – chain management
Product and service innovation	<ul style="list-style-type: none"> – new or environmentally improved material products – green financial products – environmental services – services that are less pollution and resource intensive
Green system innovation	<ul style="list-style-type: none"> – alternative systems of production and consumption that are more environmentally benign than existing systems
Environmental measures	
Environmental technologies	<ul style="list-style-type: none"> – Pollution control technologies – Cleaning technologies – Cleaner process – Waste management equipment – Environmental monitoring – Green energy technologies – Water supply – Noise and vibration control

Source: Kemp & Pearson (2007, p. 10).

Due to a limited availability of data on particular aspects of eco-innovation in selected companies, in the further part of the article we will use a modified classification of innovation OECD/Eurostat (OECD, 2005). This classification divides innovation into four basic groups:

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

- *product* innovations require improvements to existing goods (or services) or the development of new goods. Product innovations in machinery in one firm are often process innovations in another firm;
- *process* innovations occur when a given amount of output (goods, services) can be produced with less input;
- *organizational* innovations include new forms of management, e.g. total quality management;
- *presentational* innovations refer to the implementation of new design and marketing methods in order to increase firms' sales.

In our research were selected public companies listed on the Warsaw Stock Exchange within the following indices: WIG Energy, WIG Oil & Gas, WIG Basic Materials were selected for the research. Such a selection was dedicated by a peculiarity of the activity, i.e. a potentially significant influence on the natural environment. Therefore, public companies operating in the above mentioned sectors should perform a relatively high level of environmental interests.

The analysis was based on the method of digital and documentary source analysis. Moreover, survey analysis method was also used, however, due to a low return of the questionnaires it was only supplementary. 20 companies were tested including nine companies listed in the WIG Energy index, seven in WIG Oil & Gas and four in WIG Basic materials. It should be emphasized that the examined sample included ten companies listed simultaneously in the RESPECT index (social responsibility index)¹, which as companies socially responsible are obliged to pro-environmental activities. The results of the analysis were presented in Table 3.

The effects of eco-innovation activities were presented in the division into 4 groups pursuant to the adopted methodology of measuring eco-innovation. The first group includes such companies which launched a new or significantly improved product and/or eco-innovation service confirmed by different certificates and distinctions onto the market. The second group encompasses such companies which introduced a new or significantly improved eco-innovative production process. It refers to modernization activities meant to introduce a process that would limit the emission of harmful gases, the liquidation of landfills both in the company area and its surroundings. The third group includes these companies which introduced new or significantly improved organizational eco-innovations such as organizational changes in environmental issues confirmed by proper certificates

¹ In the 8th (current) edition of the RESPECT project, there are 23 companies listed.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

(ISO 14001 concerns environmental management, Eco-Management and Audit Scheme - EMAS). The fourth group lists the companies which launched new or significantly improved marketing eco-innovations such as any visible ecological activities reported on their websites and/or social responsibility reports and other forms of educational activities promoting environmental protection (e.g. the participation in educational programs and projects).

Results

The majority of the examined companies is aware that investments in innovative and ecological technologies as well as raising ecological awareness are profitable to the company. The results presented in the Table below show an uneven distribution of particular types of eco-innovation.

Table 7. The results of eco-innovation activities

Type of eco-innovation	Companies in total	The number of companies divided by indices		
		WIG e	WIG p	WIG s
New or significantly improved eco-innovation product or service launched onto the market	2	1	-	1
New or significantly improved eco-innovation production process	9	9	-	-
New or significantly improved organizational eco-innovation	12	4	5	3
New or significantly improved marketing eco-innovation	12	5	4	3

Source: the authors' own analysis.

The biggest innovativeness is visible in organizational and marketing activities. It may be due to the fact that companies are aware of the benefits resulting from this type of eco-innovation. Among 12 companies which implemented organizational and marketing eco-innovations there are as many as 10 listed in the REPSECT index (all selected for the research). Clearly, the participation in the RESPECT index facilitates the development of organizational and marketing eco-innovations.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

All companies in the WIG Energy index introduced eco-innovative production process. Two companies operate only in the area of green energy and seven companies in this index produce a part of its energy from renewable sources (including wind, water and biomass energy). Similar eco-innovations have not been introduced by the remaining companies, namely companies specializing in oil and basic material. High process innovativeness in energy companies is a result of international and domestic regulations concerning the development of low-emission economy. In Poland the assumptions to develop renewable energy were defined in numerous governmental documents. The fundamental regulation concerning energy produced from renewable sources is the Energy Law Act. The law-maker imposed on energy companies the obligation to buy electrical energy and heat produced from renewable sources of energy. In practice, it obliges the companies, the producers of 'black' energy, to buy certificates of origin or to make a compensatory payment.

A significantly low eco-innovativeness is observed in products and services. Only two companies proved any activities in this area. It may be somehow explained by lack of both market and banking incentives for the development of this type of eco-innovation.

Conclusions

The analysis of eco-innovativeness of the companies listed within selected indices showed considerable differences in terms of particular types of implemented eco-innovations. The relatively highest activity was recorded in the area of organization and marketing. It may be due to a higher awareness of the image and competition benefits which result from obeying international standards in terms of environmental management as well as initiating such activities which are socially responsible. In this respect, a particularly high activity was observed in the companies listed simultaneously in the Respect index which includes socially responsible companies. Moreover, in terms of process innovations a considerable contrast may be observed between the companies from respective indices. All selected companies listed within the WIG Energy index implement eco-innovation activities whereas the 'representatives' of the remaining indices cannot boast of any new pro-environmental processes. This crucial disproportion is justified by international and domestic regulations concerning the development of low-emission economies, which to a much greater extent and directly refer only to the energy sector. The last examined type of eco-

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

innovation in terms of product and/or services show an extremely low innovativeness of the companies. We detected only two cases of new products in our study (realized by two companies).

**Social Capital as a Key Driver of Productivity
Growth of the Economy: Across-countries
Comparison**

JEL Classification: *I31; O11; O15; O3*

Keywords: *welfare; social capital; knowledge economy*

Abstract: The aim of this work was to show the possible impact of social capital on productivity of the economy. That impact can be measured by such indicators of productivity of the economy as used in our study: the GDP, the total value added of the economy (TVE), and the GNI per total labour force. Thus, this paper was organized as follows: its first part presents the relationship between the development of social capital and productivity growth of the country in the light of the economic development theory. In this context it is pointed out that the significance of social capital as a component of the productivity potential of a given country increases when such country moves to the next stages of economic development. Therefore, social capital becomes a very important driver of the upgrading of national incomes in those countries, in which competitive advantages are based primarily on intellectual capital assets. The other part of the paper describes the methodology and the results of a research conducted on a group of 100 countries in the years 2012-2013 with an aim to illustrate the link between social capital and productivity of the economy as a whole referred to, or indicated, in the first part of the study. The results of the research allowed us to formulate a conclusion that without an appropriate ethical behaviour, not only in business, the productivity growth is

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

hampered because it translates into a lower level of trust and unwillingness to cooperate. In other words, as, among others, W. Bartoszewski stressed, "it is worth to be decent".

Introduction

Social capital as an element of intellectual capital includes, according to specialists working for the World Bank, various institutions, linkages and relationships, norms and customs that determine the quality and quantity of a society's social interactions (<http://web.worldbank.org/wbsite/external/topics/exttsocialcapital> (1.03.2015)). Social capital understood in this way is an important component of a country's soft environment, which determines the further increase in the welfare level through facilitating cooperation and collective action. Cooperation requires the creation of various types of networks and the development of trust. P. Streeten (2002, p. 10) stresses that the ability to associate depends on the degree to which communities share norms, and out of such shared norms grows trust. For F. Fukuyama, trust is the existing belief in a given community that other members of that group are characterized by honesty and cooperative behavior based on shared values and principles (Fukuyama, 1997, p. 38).

In this work social capital is regarded as one of key drivers of the country's productivity growth through its impact on the welfare level of the economy. The Organization for Economic Cooperation and Development (OECD) stresses that a good understanding of the role and drivers of productivity growth is crucial to strengthening the recovery and improving growth and living standards in the longer term (OECD, 2013, p. 7). Therefore, the article discusses social capital in the light of its influences on the formation of the productive potential of the economy. It should be pointed out that the significance of social capital as a component of the productivity potential of a given country increases with moving by this country to the next stages of economic development. In other words, social capital becomes a very important driver of the upgrading of the national income in the countries in which competitive advantages are based primarily on intellectual capital assets.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

The aim of this work is to show the possible impact of social capital on productivity of the economy. This paper is organized as follows. Its first part presents the notion of social capital and the link between development of social capital and productivity growth of the country in the light of the economic development theory.

The second part describes the methodological assumptions, the materials and the results of own research conducted on a group of 100 countries in the years 2012-2013. The aim of this research was to illustrate the mentioned links between social capital and productivity in the first part of the study. Based on the data sets of international institutions such as the World Economic Forum (WEF), the Legatum Institute (LI), and the United Nations Conference on Trade and Development (UNCTAD), the relationship among indexes of social capital and its selected dimensions as well as indicators of productivity of the economy as a whole, including the Gross Domestic Product (GDP), the total value added of the economy (TVE), and the Gross National Income (GNI) per total labour force, are analyzed. All those are based on statistical methods.

Social capital and productivity growth

The concept of social capital has been developed by many researchers; hence there are many definitions and explanations of this category. It should be emphasized in this place that the introduction of a category of social capital into economic science has enriched the latter with a socio-cultural context. The main areas of research into social capital have been set out, *inter alia*, by such great sociologists and economists as P. Bourdieu, J. Coleman, R. Putnam, D. North, M. Olson, S. Knack and F. Fukuyama.

Interesting and useful for further analysis seems to be the approach adopted by J. Coleman who describes social capital primarily as a social structure (network) made up of a variety of communities. He treats social capital as every aspect of an informal social organization that creates productive resources for one or more entities. Thus, social capital consists of institutions that enhance the benefits of an individual with cooperation and exchange (Coleman, 1988, p.95; Wildowicz-Gigiel, 2008, pp. 7-8, Libertowska, 2014, p. 96).

P. Bourdieu, in turn, defines social capital as the bonds and obligations based on reciprocity relations of human beings, which may be institutionalized in the form of social trust.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

R. Putman, the biggest promoter of social capital, understands it as “the totality of norms, networks, mutual trust and loyalty that occur in a particular social group”. He defines social capital as connections between individuals, norms and trust that arises from these relationships and can increase the productivity of a society by facilitating the coordination of activities (Przygodzki, 2004, pp. 94-95; Gajowski M., 2011, p. 57; Majewska, 2012, pp. 205-206; Majewska, 2013 a, p. 254).

F. Fukuyama was investigating social capital from a cultural perspective. A key category for him was trust. He stressed the economic dimension of trust and social capital. This approach to social capital has influenced our understanding of social capital presented in this article, because it takes into account the differences in the level of economic development of regions and countries.

In yet another explanation of social capital, the ability of people to cooperate and this cooperation being based on ethical norms and values shared by all members of a community (group) is emphasized. Social capital is therefore an immaterial effect of a collective action, the common good - both public and private.

Finally, we can say that social capital consists of norms and networks that support cooperation. Also the OECD’s definition of social capital states that it “networks together with shared norms, values and understandings that facilitate co-operation within or among groups” (Gellauff, 2003, pp. 1-2). The synergy effect, which occurs as a result of these links, and continued innovations lead to a more efficient use of production factors. In modern economies, social capital is one of the most important determinants of socio-economic development of countries.

Sociological theory distinguishes between two types of networks: bonding and bridging. Bonding, or strong-ties networks, consist of a closely knit set of connections within a specific group of people who are well aware of one another’s behaviour and reputation. These connections generally exist for a long period of time.

Bridging, or weak-ties networks, are much “thinner”. Contacts last shorter but extend to a larger group of people. People in bridging networks more easily connect with outsiders. Because of two types of networks, there are also two kinds of social capital. The main differences between the bonding and bridging social capital are the following (see: Gelauff, 2003, pp. 4-5):

- The bonding social capital is characterized by relatively low transaction costs required to make relationship-specific investments within groups,

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

and it is relatively easy to guarantee confidentiality. This situation creates economies of scale: information asymmetry is low, and it takes less effort for people to get acquainted with one another. Members of a group feel solidarity and are willing to help one another in difficult situations. On the other hand, however, antagonisms between group members and outsiders may appear, which may, consequently undermine standards that are appropriate for this particular group.

- Within the bridging social capital, members have more trust in people (which also more rapidly extends on people) from other places or other cultures or to people with other ideas. This characteristic increases the flexibility in building relationship-specific investments, generates diversity and reinforces motivation for innovation and entrepreneurship.

The long term trends show a shift from a bonding to a bridging social capital.

Various authors indicate three possible levels of analysis of this category of capital: micro, meso and macro levels (Kostro, 2005, p. 8; Łopaciuk-Gonczarek, 2012, pp. 8-9).

At the micro level (the level of a unit) the analysis focuses on the study of attitudes, relationships, norms and behaviours among individuals or groups who are in close relationships with one another (neighbourhood). The most important category which is analyzed at this level is cooperation. The unit is then examined in terms of its individual benefits from participating in networks of social relations.

At the meso level (the level of organization or community) the subject of the analysis is a group (social institution), which helps to build a greater community network and can benefit from its social capital. In this approach, social capital is a resource, which is conditioned by the existing social bonds.

And finally, at the macro level, social capital is treated as a public good and analyzed in relation to the whole of the society. Consequently, the political, social and cultural elements of the environment are taken into account, and the impact of formal institutional structures on the economic situation of society, welfare and the level of satisfaction is examined. Other important areas of study include an analysis of the credibility of a State, the scope of civil liberties available to citizens, the existence or lack of corruption and the efficiency of the administrative system of a given State.

To summarize, social capital can be viewed as the ability of a country to cooperate and work together in order to realize the common purpose of a

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

given community or network. Social capital consists of such dimensions like (see: <http://web.worldbank.org/wbsite/external/topics/exttsocialcapital>):

- different kinds of networks and collective actions,
- values and attitudes such as trust, solidarity, honesty, fairness, egalitarianism, sense of unity, equality of treatment,
- information and communication technology facilitating collaboration and increasing the transparency of government decisions,
- organizational structures, arrangements and solutions for cooperation between the private and public sectors.

The development of social capital may give many benefits. For example, social capital reduces transaction costs, corruption and the scope of social exclusion. Social capital also increases the degree of transparency and accountability of economic policy through the wider access of enterprises and citizens to information. It also strengthens cooperation between the public and private sector, which reduces the waste of public funds and increases the efficiency of jointly-implemented projects. Additionally, social capital facilitates knowledge diffusion and sharing. Those benefits of forming social capital lead to the productivity growth of the economy (see: Czapiński, 2014, p. 320; Majewska, 2013 a, 255-256; Josten, 2013, pp. 5-8; [http://web.worldbank.org/topics/social development](http://web.worldbank.org/topics/social%20development) (1.03.2015)).

However, obtainment of the above mentioned benefits of social capital depends on the level of economic development. For example, the level of trust is correlated with GDP *pc*, which indicator is often used as a proxy of prosperity. At the early stages of development, in countries that are only beginning to implement an industrialization strategy, industry located in rural areas (textile and food) is usually first to develop, and investments in more manufactured goods industries are being made much more later, first, simply to fulfil the needs of the internal market. That is why investments in human capital are so important. Governments of developing countries should also support domestic producers by making it possible to invest into different types of hard infrastructure and develop capital goods industries.

Only then will those economies start to open to foreign markets on a greater scale. In order to cope with international competition, domestic producers must implement technological improvements and learn from the rest of the world, absorb new knowledge, and, as a result, increase productivity, building together with the government a public and business environment in order to upgrade the prosperity of their own country. Thus, in such cases, human capital begins to become the main driving force of productivity growth.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

When it comes to medium-income countries, the economic policy of their respective governments should, among other things, focus on the strengthening of the industrial base and support domestic businesses in their innovation activities that require a good quality human capital. In these activities, what becomes an increasingly important task is the shaping of the socioeconomic structure of the economy, as its competitive advantages should change its character, in order to help a given country to maintain its productivity growth, and hence prosperity.

Due to the implementation of appropriate development strategies, comparative advantages can transform those based on raw materials and cheap labour in the direction of those based on capital and technology. Passing on to the next stages of economic development, frequently referred to as the knowledge economy, is closely related to the higher level of intellectual capital, of which an important part is social capital. Summing up, there is a systematic relationship between the socioeconomic structure of the country, the nature of the sources of productivity growth, and the kind of political economy, which in turn reflects its level of economic development. For example, in the opinion of J. Czapiński, the important role of a human capital as a factor of wealth growth in poorer countries explains why Poland has been so far developing at a good pace, irrespective of its low level of social capital. As Czapiński sees it, the continuation of investments in human capital may turn out insufficient to sustained development (see: Czapiński, 2014, pp.323-333; Jantón-Drozdowska & Majewska, 2013, pp.45-48; Rizwan et al., 2011, pp.270-277).

Failure to take into account the above-mentioned interactions (widely presented in literature on the achievements of the later stages of economic development) in research methodology could lead to a controversial conclusion that social capital does not increase productivity. This does not mean, however, that in an economy where the level of social capital is too low, or if there is so-called negative social capital, as is in the case of corruption and nepotism, its impact on productivity does not appear, or will not be an impediment to economic development (see for example: Streeten, 2002, p. 11-13).

Methodology and materials of the research

The study covered a group of 100 countries included in the rankings of the World Economic Forum, the Legatum Institute and the UNCTAD statistics. The research period covered the years 2012-2013 as it was possible

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

to obtain for that period the latest dataset which allowed us to estimate all selected indicators for the analysis of social capital and productivity for the economy as a whole.

The productivity measures for the total economy in our study are the GDP per total labour force (GDP *pe*), the present Total Value Added of the economy per total labour force (TVE *pe*) and the nominal GNI per total labour force (GNI *pe*). Gross National Income is defined as GDP plus net receipts from abroad of wages and salaries and of property income plus net taxes and subsidies receivable from abroad (see: OECD, 2013, pp. 14-32). The three indicators of economic performance and income levels of a given country: GDP, TVE, and GNI are expressed in current prices converted to U.S. dollars at official exchange rates. They are sourced from the UNCTAD statistics reports, such as total labour force data. The UNCTAD defines total labour force as persons aged 15 and older who are engaged or seeking work. Thus, the estimates of total labour force can be treated as potential employment of the economy.

This variable of potential employment of the economy has been decided upon since it was impossible to obtain data free on real employment and hours of work for such a large set of countries from other sources, such as for example the OECD or the International Labour Organization. The indicators of productivity level of the economy are calculated by dividing the GDP, TVE and GNI of a given country by its total labour force (<http://unctadstat.unctad.org/wds/reportFolders/reportFolders.aspx>). This dataset is presented in Table 1.

Table 8. GDP *pe*, TVE *pe*, GNI *pe* in USD in the surveyed group of countries in 2012

The surveyed countries are presented according to the level of GNI *pe* from the highest to the lowest position in this indicator of productivity in 2012. The comparison of three productivity indicators shows big differences in their highs across the surveyed countries. While only 26 countries

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

displayed the productivity level measured by three indicators higher than USD 50 000 per employee in 2012, 51 countries achieved the productivity level lower than USD 20 000 per employee. One of the many possible factors causing the observed divergence in productivity levels, can be social capital. Its role in driving the economic growth and changes in living standards, hence prosperity, is still growing in the present world economy.

Specialists working for the independent British research center the Legatum Institute argue that social networks and the cohesion that a society experiences when people trust one another have a direct effect on the prosperity of a country. Firstly, as a synthetic index of social capital in a given country, has been selected the index of the Legatum Institute. It is a part of the aggregate indicator of economic prosperity and quality of life. The Legatum Social Capital Index measures countries' performances in two areas: social cohesion and engagement, as well as community and family networks. In order to estimate this social capital index, the Legatum Institute assesses how factors such as volunteering, helping strangers, or donations to charitable organizations influence the economic and life satisfaction of the populace as a whole. The index also includes such dimensions of social capital as the levels of trust in a society, the manner in which citizens believe they can rely on others, and how marriage and religiosity provide support networks that improve wellbeing (<http://www.prosperity.com/social.aspx> (1.03.2015)).

The authors have added their own social capital index based on the indicators published in The Global Competitiveness Report 2013-2014. This year's Report features a number of 148 economies, and contains a detailed profile for each of the economies included in the study, as well as an extensive section of data tables with global rankings covering over 100 indicators. The indicators sourced from The Global Competitiveness Report included in our proposition of a social capital index, come from the executive opinion survey the participants of which are business executives. Respondents estimate the presence of a given factor in their country on the seven-point scale, where 1 refers to the lowest level of this factor, and 7 the highest (the best situation). Therefore, this aggregate social capital index puts more emphasis on the level of social capital from the business sector point of view than the Legatum Social Capital Index, and is called by authors the Business Social Capital Index. In constructing our aggregate index, and thus in the selection of variables, we remembered of the recommendation that individual indicators should describe different aspects of the analyzed phenomenon. Therefore, the two analyzed indexes of social capital, that is

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

the Legatum Institute's one and ours, are mutually complementary, creating together a more comprehensive overview of the social capital level in a given country.

The Business Social Capital Index includes 6 dimensions of social capital:

- a) Public trust in politicians: In your country, how would you rate the ethical standards of politicians? (1 = extremely low; 7 = extremely high) (WEF, 2013, p. 413).
- b) Transparency of government policymaking that affects business activities: In your country, how easy is it for businesses to obtain information about changes in government policies and regulations affecting their activities? (1 = extremely difficult; 7 = extremely easy) (WEF, 2013, p. 421).
- c) Ethical behavior of firms: In your country, how would you rate the corporate ethics of companies (ethical behavior in interactions with public officials, politicians and other firms)? (1 = extremely poor—among the worst in the world; 7 = excellent—among the best in the world) (WEF, 2013, p. 426).
- d) Cooperation in labor-employer relations: In your country, how would you characterize labor-employer relations? (1 = generally confrontational; 7 = generally cooperative) (WEF, 2013, p. 488).
- e) State of cluster development: In your country, how widespread are well-developed and deep clusters (geographic concentrations of firms, suppliers, producers of related products and services, and specialized institutions in a particular field)? (1 = nonexistent; 7 = widespread in many fields) (WEF, 2013, p. 526).
- f) University-industry collaboration in R&D: In your country, to what extent do business and universities collaborate on research and development (R&D)? (1 = do not collaborate at all; 7 = collaborate extensively) (WEF, 2013, p. 537).

Each component of the Business Social Capital Index has been assigned a weighting 0.166 (16.66%), which means that it is a symmetrical weighted aggregate index. The Business Social Capital Index was calculated according to a typical procedure. For each country, the total value of this index was calculated by summing the results of multiplying the 2012-2013 average values of 6 indicators presented in the World Economic Forum's annual Global Competitiveness Reports by the weight assigned to them (see: Archibugi & Coco, 2004, p. 175-179; Majewska, 2013 a, pp. 258-259).

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

Next, Spearman's rank and Pearson's linear correlation analysis were carried out to examine the relationship between social capital and productivity for the surveyed economies and for each distinguished group. Due to the above stressed fact that the role of social capital as a component of the productivity potential of a given country increases with achieving by this country the next stages of economic development, the 100 countries were divided in two groups composed of 50 economies each, according to their social capital level. First, in the Spearman's rank correlation analysis, the social capital level was measured the average position of its aggregate indexes. Then, in the Pearson's linear correlation and a cluster analysis, the sum of values of social capital indexes was measured. In the case of Spearman's rank correlation analysis, there was no need to normalize the data, because that analysis is carried out for the examined variables describing the 100 countries expressed in their positions according to these variables in the rankings considered in our study (see Table 2). Whereas all variables included in the Pearson's linear correlation and cluster analysis were transformed into natural logarithms, which is the recommended procedure in such studies (see.: Majewska, 2013 b, pp.177-178).

Then a cluster analysis was performed too, as it allowed examination of similarities and dissimilarities regarding the indicators of productivity and social capital's dimensions between the analysed groups of countries. The cluster analysis was carried out with the help of an agglomeration method based on Chebyshev and 1-r Pearson distances for grouping the features of a selected group of countries. The Chebyshev measure is a generalized version of Euclidean distance between variables, and it normalizes the differences in distances to the extent necessary for the identification of similarities and dissimilarities between the characteristics of countries divided into different social capital-level groups. In the case of 1-r Pearson measure of distance, variables are grouped for a given set of countries by way of inclusion of the Pearson's multiply correlation coefficients among a number of variables that are analyzed simultaneously. The coefficient of multiple correlation is a measure of how well a given variable can be predicted using a linear function of a set of other variables. This kind of measure of distance allows to present the results of the multidimensional relationships between the variables of productivity and social capital. The results of the two kinds of cluster analysis have been presented graphically in a dendrogram the branches of which represent distances between the examined variables for selected groups of countries.

Results of a research into the link between the level of social capital and productivity growth

In order to ensure comparability of data from different sources it was decided to compile the positions occupied by a given country of concerned rankings of social capital and productivity. Table 2 shows the positions of 100 countries obtained in analyzed rankings for the years 2012-2013. First place achieved by a country in all selected rankings means or the highest level of productivity indicator or the highest scale of social capital development (or its dimension like ethical behavior of firms) across surveyed economies. For example, in the Legatum Institute ranking of social capital (39 rank) and ethical behavior of firms (43), Poland achieved the best position, while it was placed in the worst for the indices of transparency of government policymaking affecting business activities (86) and for the state of cluster development (81). Therefore, in the Business Social Capital Index Poland attained much lower position – 69.

In 2012 the top 5 countries in the LSCI ranking were Norway, Denmark, Australia, the New Zealand, Finland, whereas the five countries classified at the lowest positions were Bangladesh, Turkey, Rwanda, Pakistan, and India. According to the BSCI ranking leaders in 2012-2013 were Singapore, Switzerland, Finland, Sweden, Norway, while the last five places were occupied by Greece, Nepal, Argentina, Algeria, and Venezuela. As regards the level of social capital, the measured average position in two its aggregate indexes, in the researched period among the top 5 countries were Norway, Finland, the New Zealand, the Netherlands, and Sweden. In 2012, the bottom 5 countries according to this indicator were Mozambique, Algeria, Nepal, Romania, Bangladesh.

Source: own calculation based on WEF 2013, pp. 413, 421, 426, 488, 526, 537;
<http://unctadstat.unctad.org/ReportFolders/reportFolders.aspx>. (1.03.2015).

In 2012-2013 public trust in politicians was the highest in Singapore, the United Arab Emirates, Norway, the New Zealand, Sweden, and the lowest in Dominican Republic, Venezuela, Paraguay, Czech Republic, Argentina. In transparency of government policymaking affecting business activities, the best results across the surveyed countries achieved Singapore, Finland, Hong Kong, the New Zealand, and Switzerland. For businesses to obtain information about changes in government policies and regulations affecting their activities were the most difficult in Mali, El Salvador, Italy, Argentina and Venezuela.

In 2012 to the five countries classified at the highest positions in the ranking of ethical behavior of firms were the New Zealand, Finland, Singapore, Switzerland, and Norway. The lowest places in this dimension of social capital occupied Romania, Venezuela, Paraguay, Argentina, and Bangladesh. According to the cooperation in labor-employer relations ranking leaders in 2012 were Switzerland, Singapore, Denmark, Norway, and the Netherlands. The most confrontational labor-employer relations occurred in Romania, Argentina, Nepal, Venezuela, and the South Africa.

In 2012 to the top 5 surveyed countries, where the state of cluster development were the most widespread in many fields, belonged Taiwan, Italy, the United Arab Emirates, Germany, and Switzerland. In this dimension of social capital the ranking bottom reached Zimbabwe, Ukraine, Mongolia, Venezuela, and Moldova. In 2012 the five countries classified at the highest positions in the extent of university-industry collaboration in R&D were Switzerland, Finland, the United States, Singapore, and the United King-

Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

dom. The lowest places in this dimension of social capital attained Nepal, Moldova, Egypt, Bangladesh, Algeria.

Table 3 presents the results of the research obtained from estimating Spearman's rank correlation between positions of surveyed countries in rankings of social capital indexes, its dimensions, and productivity indicators in the years 2012-2013. In the case of a whole set of countries and a group of countries with the higher level of social capital all correlation coefficients are positive and statistically significant on the level 0.05. However, for a group of countries with the lower level of social capital all correlation coefficients are not statistically significant on the level 0.05. The same results obtained with the help of the method of Pearson's correlation analysis (Table 4), which was performed additionally to increase the reliability of the outcomes. In the case of Pearson's correlation analysis we correlated the values of social capital and productivity variables. Reminding, the values of variables have been previously standardized, and countries were divided into two groups of higher or lower level of social capital according to the sum of the values of LISCI and BSCI.

Source: own calculation based on data from table 2.

The values of Spearman's rank correlation coefficients show that the higher position of a given country according to the level of social capital, the better place in the rankings of productivity. The considered links between an increase in social capital and a higher level of productivity has been confirmed also by Pearson's linear correlation analysis. Moreover the

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

research results have indicated that according to the theory of economic development path of a country, the significant impact of social capital on the level of prosperity appears only after a country has accumulated a sufficient stock of it. This requires different kinds long-term transformations in soft and hard infrastructure of the national economy.

An important component of such soft infrastructure is just social capital, including examined in this study its dimensions. The values of correlation coefficients presented in Table 3 and 4 indicate that the strongest interactions occur between the level of productivity and such dimensions of social capital as ethical behavior of firms and university-industry collaboration in R&D. The values of correlation coefficients are the lowest for the cooperation in labor-employer relations and transparency of government policy-making affecting business activities.

<http://unctadstat.unctad.org/ReportFolders/reportFolders.aspx>. (1.03.2015).

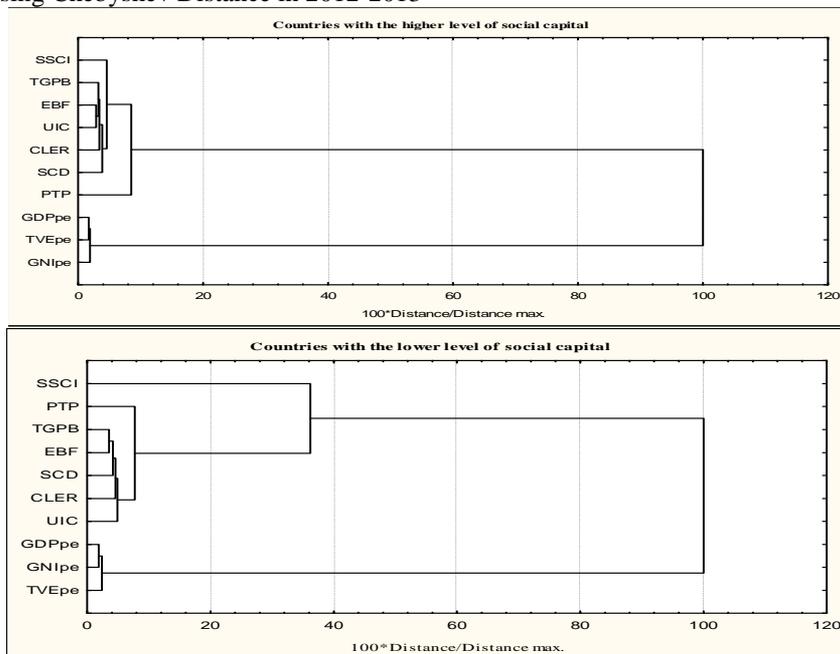

Two separate cluster analyses were made to check whether the above introduced characteristics of interactions between the productivity and social capital levels took place for the two groups composed of 50 economies divided according to the social capital level. In this case the social capital

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

level was measured by the following proxy - the sum of values of social capital indexes. The results of the cluster analysis here show which clusters of variables are more typical for these groups of countries.

The cluster analyses confirmed that for a group of countries with higher level of social capital are the strongest links between social capital and its dimensions and the value of productivity indicators than in the case of a group of countries with lower level of social capital. In two groups of analyzed countries we deal with one main clusters of productivity variables joined, at different longer nodes, by the second main cluster contained the variables of social capital. In the examined countries with higher level of social capital the variables of social capitals and the productivity indicators are closer in terms of distances between them. It is more visible in the case of 1-r Pearson measure of distance.

Figure 1. Dendrogram for Selected Variables of Surveyed Countries Clustered Using Chebyshev Distance in 2012-2013

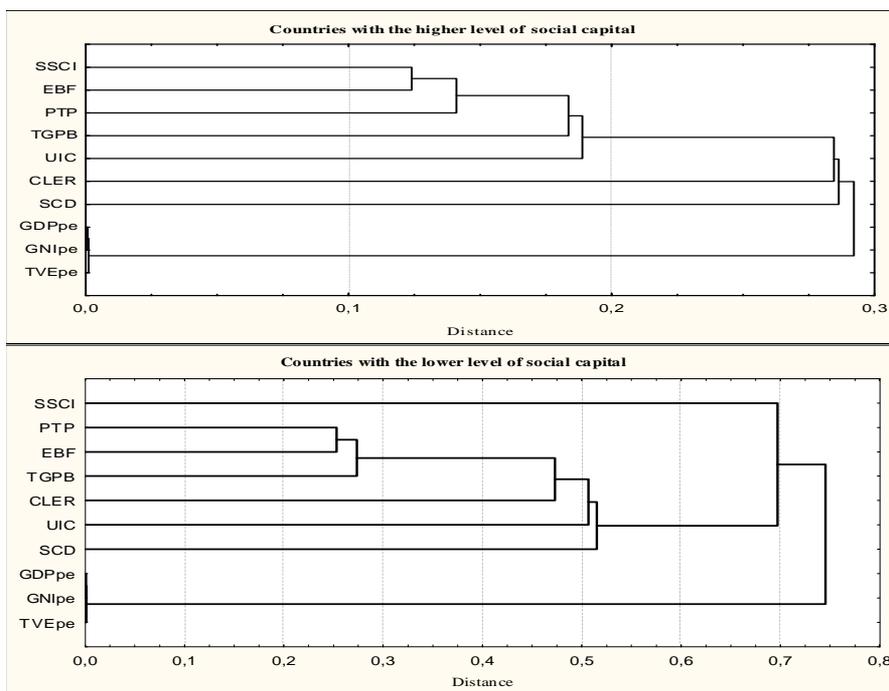

Source: own calculation based on WEF 2013, pp. 413, 421, 426, 488, 526, 537; <http://unctadstat.unctad.org/ReportFolders/reportFolders.aspx>. (1.03.2015).

Countries with higher level of social capital demonstrate therefore explicitly a larger similarity of analyzed features. Indicators of social capital and productivity change in a similar manner, and almost all at once, and their changes are correlated with each other. In other words, the variables that we have examined may influence one another more strongly in the group of countries with higher level of social capital than in the group of countries with lower level of social capital.

The results of our study again suggest that social capital in the high-income countries is more important element increases the productivity, comparing to countries with lower its level, where the drivers of productivity growth, and thus prosperity, are still different, which is explained by the economic development theory (see Introduction).

Figure 2. Dendrogram for Selected Variables of Surveyed Countries Clustered Using 1-rPerason Distance in 2012-2013

Source: own calculation based on WEF 2013, pp. 413, 421, 426, 488, 526, 537; <http://unctadstat.unctad.org/ReportFolders/reportFolders.aspx>. (1.03.2015).

Conclusions

The results of our study have shown that social capital is an important source of raising productivity of the national economy, provided that the country is already in a later stage of economic development. This is related to the fact that the previous growth drivers of wealth, associated mainly with the improvement of hard infrastructure and revenues from foreign trade based on labour-intensive and capital-intensive comparative advantages, have been diminishing.

To ensure further growth in productivity, certain actions will necessary, including actions aimed at the development of a soft business environment, strengthening of cooperation between the public and private sector, higher professionalization and better transparency of state policies. All these help to rebuild trust in socio-economic relations, but requires the promotion of ethics, fairness, and well understood social justice. This happens because without honesty and ethical behaviour, there is no trust, and without trust, there is no real cooperation and integration, or, consequently, resulting from them different types of synergies. Our research has led us to the conclusion that without appropriate ethical behavior productivity growth will be hampered, because it translates into a lower level of trust and unwillingness to cooperate. In other words, like for example W. Bartoszewski stresses, "it is worth to be decent".

**Investment Attractiveness of Central
and Eastern European Countries in the light of
New Locational Advantages Development**

JEL Classification: *F21; O33; O52; O57*

Keywords: *investment attractiveness; Central and Eastern European countries*

Abstract: The aim of this work was to present the similarities between the components of competitiveness and investment attractiveness as two complementary categories, and to show the role of new locational advantages in determining the level of investment attractiveness of a country. The other objective of this paper was to provide a comparative analysis of Central and Eastern European countries in terms of their investment attractiveness. Thus this paper was organized as follows: the first part of the paper focused on a country competitiveness and the traditional and new location advantages that determine its investment attractiveness in view of direct investment inflows in the light of M. Porter's model of a diamond, an eclectic paradigm of J. H. Dunning and new growth theories. The second part presented the results of investment attractiveness analysis including selected countries of CEE in the years 1995-2013. Comparing the investment attractiveness of Central and Eastern European countries shows that rather a narrow group of countries attract a greater amount of FDI and many more countries have experienced a decline in FDI. Therefore, the research results allow the conclusion that Central and Eastern Europe reduced its investment attractiveness over the past years. This means that the majority of Central and Eastern European countries are becoming

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

less successful in attracting FDI, and therefore in shaping the environment in which foreign companies wish to conduct their business.

Introduction

The aim of this work is to present the similarities between the components of competitiveness and investment attractiveness as two complementary categories, and to show the role of new locational advantages in determining the level of investment attractiveness of a country. As it will be stressed during our consideration, competitiveness is frequently associated with productivity, where inputs are transformed into goods and services. Therefore it can be stated that the larger and faster of obtaining opportunities for productivity growth in a particular country or a group of countries, understood in this paper as the location of economic activity, the greater competitiveness of the area in attracting various types of investments. In the process of the upgrading of a country's competitiveness, and consequently its investment attractiveness, an increasing role is attributed to new locational advantages compared to traditional determinants of foreign investment inflow, the assets of which constitute intellectual capital.

The other objective of this paper is to provide a comparative analysis of Central and Eastern European countries in terms of their investment attractiveness. Thus this paper is organized as follows: the first part of the paper focuses on a country competitiveness and the traditional and new location advantages that determine its investment attractiveness in view of direct investment inflows in the light of M. Porter's model of a diamond, an eclectic paradigm of J. H. Dunning and new growth theories. The second part presents the results of investment attractiveness analysis including selected countries of Central and Eastern Europe (CEE) in the years 1995-2013. The source materials for analysis of investment attractiveness of CEE countries were data and indicators published by the United Nations Conference on Trade and Development (UNCTAD).

Competitiveness as a global category

Competitiveness is a complex and multidimensional concept that is applied widely to various social and economic circumstances. Consequently, there are many definitions of competitiveness used by different authors in various contexts and for varied research purposes. The concept of competitiveness, particularly in terms of its defining factors and measures, is not

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

unambiguous¹. There is no doubt however that this category is inextricably connected with performance of particular companies. When related to the enterprise, competitiveness means the capacity to compete in the global market. In this sense it is frequently understood as synonymous with the market share and gains of companies with significant shares in the product markets. Such a static approach to competitiveness can in no way be adopted as a yardstick for any analysis. A large market share is rather a result of a high competitive position of a company.

In relation to the entire economy, however, competitiveness can be defined as the capacity to produce and sell competitive products on the domestic and foreign markets, with the real income growing (Sachwald, 1994, p. 32). This condition is very important in the dynamic approach to competitiveness because economy must retain the capacity to grow and create possibilities for raising the society's standard of living. So, the productivity of employed resources, i.e. labor and capital, is more important both from the point of view of the companies and the economy as such. Productivity is the value of an output produced by a unit of labor or capital. Its level depends on the product quality and its characteristics as well as on the efficiency of production (see: Jantóń-Drozdowska, 1998, pp. 231-232).

The World Economic Forum (WEF) defines competitiveness as a set of institutions, policies and factors that determine the level of a country's productivity. The level of productivity, in turn, sets the level of prosperity that can be reached by an economy (WEF, 2013, p. 4). The WEF measures competitiveness using a global competitiveness index according to which a weighted average is composed of many different components that are grouped into 12 pillars of competitiveness: institutions, infrastructure, macroeconomic environment, health and primary education, higher education and training, goods market efficiency, labor market efficiency, financial market development, technological readiness, market size, business sophistication, innovation (WEF, 2013, pp. 4-9).

Competitiveness is treated as a global category but its various types or levels should be distinguished. Authors dealing with this problem suggest different approaches (see: Porter, 1990, Jantóń-Drozdowska, 1998, Nezeys, 1993). For the purpose of this study it seems justifiable to point out to three types of competitiveness, which allow combining the analysis in the micro-economic (company) and macroeconomic (economy) scale. They are:

¹ Different explanations for competitiveness have been reported by M. Porter (1990, pp. 3-6).

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

- cost-price competitiveness,
- technological competitiveness, prerequisite for differentiation,
- structural competitiveness.

Gaining the competitive advantage in at least one of the three above mentioned areas, and assuming a good position in the other two, constitutes a condition for a success in the global market.

An organization operating in the competitive environment can gain advantage if its production costs are lower than those of its direct competitors. It means that it is able to use the productive elements in the most efficient way. The relative lowering of production costs allows an enterprise to:

- increase its sales and market share,
- generate more cash flow than its competitors do,
- survive recession in the economy or sector.

Companies that want to gain a competitive advantage in costs and prices can do that in a number of ways, which may link into the effect of experience (Porter, 1980, pp. 11-13, Jantón-Drozdowska, 1998, pp. 232-235). This category consists, first of all, of:

- economies of scale, which are related not only to the volume of production in the plant or company but also to other functional areas in the organization. Their realization optimizes all elements of the value chain. Economies of scale are essential to the competitor's differentiation not only at one time but also over the time: the value necessary to gain competitive advantage changes with the expansion of the market,
- permanent learning and job training of staff and management, which determines an increase in productivity and improvement of the system and operating concepts. Frequently, competitors are not able to lower the costs to the level of those of the leader by means of a simple increase in the productive capacity – this advantage is related to the time that they need to increase their professional knowledge,
- innovation, which is an essential element of the experience effect and the basis for differentiation. Innovation is usually understood as an improvement in technology and better methods of doing things. Innovation results in product and process changes, new approaches to marketing and new forms of distribution.

The cost of production and prices also depends on the environment in which an enterprise operates. It determines factors influencing the total unit cost which consists of labor cost, capital cost, tax charges and cost connected with the system of distribution. Moreover, the costs and product prices

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

are affected by the foreign rate, the exchange rate policy and increasing risk.

Porter argues that technological competitiveness of a company and a country is determined by investment and innovation. At the end of rational investment outlays companies create modern and efficient facilities, equipped with the most recent technology, bringing economies of scale. Acquiring technology through licenses and joint ventures is an investment that also enables gaining a competitive advantage. Investment ventures carried out by companies and governments result in improved productive elements and changed structures, strategies and competition (Porter, 1990, p. 549). Consequently the domestic demand, which influences the sales of produced goods, increases. The role of the state in stimulating investment should be underlined. Government's interventions in channeling capital towards particular industries may play an important role, promoting risk taking, providing temporary protection to encourage the entry of domestic rivals and the construction of efficient scale facilities, stimulating and influencing acquisition of foreign technology and encouraging exports (Porter, 1990, p. 551).

Investment is inextricably connected with innovation, which at the company level is essential for technology and product differentiation, and which in turn enables gaining segments of the global market under existing competitive conditions.

Next, at the industry level, factors determining the innovative activity are stimulated by the changes in demand and prices and the industry-specific technology. The latter is determined by the pressure of international competition and the rate of technological development. Technological advancement of suppliers and buyers is also of relevance.

At the country level, determinants of innovative activity can be presented in M. Porter's model of a diamond (Porter, 1990, p. 533, Jantón-Drozdowska, 2009, pp. 68-71), which covers four components: factor conditions, demand conditions, related and supporting industries, and finally firm strategy, structure and rivalry. Porter stresses, that a firm, an industry or a country, which wishes to be competitive should be able to create specialized factors. The more sophisticated the consumer demand is because of rising personal incomes, the higher level of education, increasing the desire for convenience, while the more invigorating role of domestic rivalry, the more it stimulates innovative activity.

Finally, structural competitiveness is most often described as an indicator of general performance which summarizes the set of non-price determi-

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

nants of competitiveness. In the notion of structural competitiveness the sources of competitive advantage are especially emphasized. It is not just a composition of trade which brings the competitive advantage, but the structure of economy. In this approach competitiveness is the result of multiple interactions within national economies, and is systemic in nature. Some nations are more competitive because of a higher efficiency of their entire production and distribution systems and their capacity to innovate. This approach again introduces firms as crucial actors. One of the main components of structural competitiveness is the set of relationships between firms and their national environments.

The interactions between firms' and nations' competitiveness has two aspects. On the one hand, firms that operate in an economy determine its competitiveness, and on the other hand, firms are largely dependent upon their environment for their development. At this point we return again to the set of four factors (diamond) of M. Porter in which numerous interactions between firms' and nations' competitiveness are analyzed.

**Traditional and new locational advantages determining
investment attractiveness for FDI**

Nowadays, with increasing the global competition, countries have become influential in international business operations. Differences in national values, culture, economic structures, institutions and histories contribute to competitive success. The national environment influences national competitiveness through the development of particular characteristics of resources and capabilities and through its impact on the conditions for innovation. The impact of country competitiveness on FDI and TNC can be characterized by four points – they also decide on the country attractiveness (see: Shenkar & Lou, 2004, pp. 127-128):

1. country competitiveness affects an TNC's selection of its global operations location (by e.g. cheap labor, abundant materials, large market demand);
2. country competitiveness affects an TNC's industry selection. For diversified corporations, it is important to choose a foreign industry which will fit with its global product portfolio and benefit from industry structure differences between home and host countries. A country's competitiveness is industry-specific, that means that no country can maintain high competitiveness in every industry. Thus, a more important question

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

to solve by firms is which industry in the target country is superior in terms of environment and competitiveness;

3. country competitiveness affects an corporation's innovation and capability building. Trade and FDI pattern often reflect the sectors favored by a country's organizing and technological strength and these patterns promote further expansion and investment in these capabilities. The variations of country competitiveness relate to differences in organizational and institutional capabilities. So, investing and operating in a country with superior organizing and technological strengths companies can learn more from local partners and host country business;
4. country competitiveness affects an TNC's global strategy. As it was said above, a country's competitiveness is reflected in different elements, including among others rich resources, strong and sophisticated market demand, efficient government administration and superior infrastructure for innovation. This diversity enables companies to globally differentiate their internationally split up functions and businesses so as to leverage the advantage of various countries' competitiveness.

Country competitiveness should be then analyzed not only by international institutions and countries but also by transnational corporations to make a good decision where – in the sense of country and industry – to invest. This explains also why investment attractiveness is considered in the relevant literature either as a component of country competitiveness or as a result of competitiveness development by different institutions established for this purpose.

Country competitiveness is often viewed as combining the competitive advantage of firms and the comparative advantage of a territory. These two collectively contribute to the increase in social income. Therefore, a country's competitiveness can be studied at both the firm and the regional, levels, in the latter case covering also investment attractiveness analysis. This is related to the fact that researches of regional competitiveness frequently refer to M. Porter's model of a diamond as well. A good example is the definition of the European Commission for which regional competitiveness means the ability to produce goods and services which meet the test of international markets, whilst at the same time maintaining high and sustainable levels of income, or more generally, the ability of (regions) to generate, while being exposed to external competition, relatively high incomes and employments levels. In other words, for a region to be competitive it is important to ensure both quality and quantity of jobs (Budd & Hirmis,

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

2004, pp.1015-1028, Dimian & Danciu, 2011, pp. 67-78, the European Commission, 1999, pp. 71-146).

Countries, as locations of economic activity, compete with each other for investment through the ability to attract different types of international capital flows which requires knowledge and innovation. The transfer of innovations by international capital flows like FDI can stimulate the emergence of new knowledge generation and spillover effects of knowledge dissemination to other firms in the recipient area. In this situation FDI as a channel of knowledge spillovers and a factor stimulating local firms to learn in order to cope with the pressure of international competition can support the modernization and growth of technological progress in the recipient country. FDI can also help improve productivity by transferring soft technology to host country operations. Therefore, according to the specialists working for the UNCTAD, mobilizing investment and ensuring that it contributes to sustainable development is a priority for all countries (Budd & Hirmis, 2004, pp.1015-1028, Kitson et al., 2004, pp. 991-999, Majewska-Bator & Jantón-Drozdowska, 2007, pp. 115-127, UNCTAD, 2008, pp.149-168, Ushakov, 2011, pp. 159-169, UNCTAD, 2012, pp. 97-160).

In the literature of the subject, investment attractiveness is usually defined as a set of advantages and shortcomings of an investment location. Therefore, investment attractiveness can be seen as the cumulative outcome of a number of factors which create an environment that influences the business activities of all enterprises located there. An assessment of investment attractiveness is the basis for selecting a particular location where foreign investments will be carried out. Foreign investors, choosing the future location of capital investment, first assess the attractiveness and risks associated with a given region, and then the attractiveness of a local market. The second component of the eclectic paradigm (OLI) is the locational attractions (L) of alternative areas, for undertaking the value adding activities of MNEs. The locational advantages of countries in the eclectic paradigm are a key determinant of the foreign production of MNEs. According to Dunning the more the immobile, natural and created endowments which firms need to use jointly with their own competitive advantages favor a presence in a foreign, rather than domestic, location, the more firms will choose to augment or exploit their ownership (O) specific advantages by engaging in FDI. J. H. Dunning argue that explanatory variables of investment attractiveness differ according to the motives for FDI, its sectoral composition, the home and host countries of the investing firms, and a variety of firm specific considerations. The dependence on the adopted busi-

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

ness internalization strategy is also attributed to different meanings of individual factors that determine investment attractiveness (Dunning, 1998, pp. pp. 45-66, Dunning, 2002, pp. 83-99, Jantoń-Drozdowska & Majewska, 2002, pp. 231-251, Majewska, 2005, pp. 79-110, Dunning & Lundan, 2008, pp. 93-115, Pierścioneck, 2011, pp. 115-119, Hildebrandt et al., 2013, pp.5-6).

Investment attractiveness can be measured by many factors that are very often called, following the eclectic paradigm of J. H. Dunning, locational attractions or specific advantages of different host countries. These factors create jointly an optimum portfolio of locational advantages of a given recipient territory. There are mainly economic, social and political features of the country in which firms are seeking to invest. Dunning, like other authors, emphasizes the emergence of new locational variables as a result of the knowledge based economy's development and the growing importance of various types of network relations within which a business can be more easily and effectively run on domestic and foreign markets. As Dunning described, this is connected with systematic structural changes in the global economy – notably, the maturation of the knowledge based economy and the emergence of the Internet as a dominant technological force, as well as an increase in intellectual capital and other kinds of intangible assets. Dunning argues that these systematic changes and their geographical significance have fundamentally altered the parameters affecting the locational preferences of firm and the actions which have to be taken by national and sub-national governments. Therefore, Dunning stresses that governments need to give more attention to identifying and providing the locational bound resources and capabilities sought by foreign investors: asset of unique (and non-imitable) competitive advantages.

The increasing importance of new type of locational determinants has caused that in shaping a favorable environment for FDI should start to focus more on government policies aiming to develop endogenous comparative advantages in terms of a new growth theory. According to new growth theories the structural changes in a country speed up owing to the creation and implementation of innovations and by creating infrastructure allowing to facilitate the emergence of knowledge spillovers and their external effects. In this context, Dunning emphasizes the role of private and public created location bound assets like for example supportive educational and technological infrastructure, and the role of governments in encouraging entrepreneurship and the innovatory contributions of small and medium-sized enterprises. In other words, governments should provide the appropri-

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

ate economic and social infrastructure that creates an environment useful for the development of distinctive and hard to copy locational bound created assets.

It should be noted here, that not all enterprises will be seeking a new type of assets in foreign markets because the FDI motives continue to be the more traditional locational advantages of host countries, such as variables of labor, materials and transports costs, or the size and prosperity of the local market. In this context, scholars have identified four main types of foreign-based MNE activity: market seeking or demand oriented FDI, resources seeking (e.g. minerals, unskilled labor) or supply oriented FDI, rationalized or efficiency seeking FDI, and strategic assets seeking FDI.

A good example of foreign investors who sought traditional locational advantages was FDI in the period of political and economic transformation in Central and Eastern Europe countries. Then the integration with the global economy led to inflows of foreign investments mainly looking for markets and resources. Underfinanced, and infrastructure-delayed Central and Eastern Europe during the transition period was perceived as an attractive market for investment to many Western companies, primary in labor- and resources-intensive industries. Firms invested in this area through different types of economic links with local companies like joint ventures and other strategic alliances. It was preceded by an analysis of investment risk and locational advantages of CEE countries depending on the strategic objectives of foreign investors (Porter, 1994, pp. 35-39, Dunning, 1995, pp. 461-491, Dunning, 1998, pp. 45-66, Dunning, 2002, pp. 2-29, 83-93, 121-134, Jantoń-Drozdowska & Majewska, 2002, pp. 231-251, Dunning & Lundan, 2008, pp. 63-78, 116-144, 383-399, Majewska-Bator, 2010, pp. 48-63, Dimian & Danciu, 2011, pp. 67-78).

For example, according to the endogenous growth theory, the key determinants of a country's competitiveness in terms of investment attractiveness are the following factors associated with strategic assets seeking FDI (Dunning, 2002, pp. 95-97, 121-128, 185-186, Majewska-Bator, 2010, pp. 141-203, Dimian & Danciu, 2011, pp. 67-78, Hildebrandt et al., 2013, pp. 15-40):

- quality of national and local infrastructure and institutional competence in the area of accumulation of knowledge, exchange of information, and improving learning experiences.
- different kinds of expenditures on information and communication technology (ICT).

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

- different kinds of expenditures on research and development and other instruments of economic policy conducive to the intensification of business R&D activities and knowledge accumulation, which is connected with spatially related innovations and local firm-specific knowledge-intensive assets useful in the wealth-creating process.
- investment in human capital, especially in the growth of technical knowledge resources, quality of state educational systems and education level of human capital, the effects of which are visible in the availability and price of skilled and professional labor.
- activities that foster entrepreneurship and collective learning connected with the availability of local partners to jointly promote knowledge.
- effective dissemination of knowledge and supporting this process through the creation of information and social collaborative networks.
- specialized areas like various type clusters and techno-parks and their spillover and synergies effects.
- Whereas the traditional locational advantages include, among others, such factors as:
 - the presence and cost of traditional factors endowments, e.g. availability, quality and price of natural resources and labor, exchange rate, transportation costs, comparative advantages of immobile assets like labor, land, and artificial barriers to trade.
 - demand levels and patterns associated with current and future capacity of sales markets and the level of economic development.
 - external economies of scale and scope, e.g. urbanization economies as the availability of transport and communications facilities and municipal services, the availability of a specialized business service not specific to a particular activity, a pool of qualified labor, supply related clusters and the availability and quality of adjacent markets, and the degree to which firms can exploit them in a given location.
 - availability of financing, fiscal incentives, quality of administrative and legislative framework, opening and functioning of markets, legal regulations concerning operation of foreign business entities and special privileges for foreign investors.
 - various types of hard and soft infrastructure like the physical facilities as transportation, electricity and telecommunications infrastructures, institutions and organizational structures and social infrastructure (e.g. health or labor market infrastructure).
- distance related transaction costs as inter-country cultural differences, e.g. the need for marketing research and negotiation costs.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

- macroeconomic circumstances for maintaining sustainable development, such as political risk and rapid changes in exchange rates, the levels of inflation, interest rates, unemployment indicators, GDP and other variables influencing economic growth and development (Dunning, 1995, pp. 461-491, Dunning, 2002, pp. 95-96, Jantoń-Drozdowska et al., 2002, pp. 231-251, Jantoń-Drozdowska & Majewska, 2002, pp. 231-251, Budd & Hirmis, 2004, pp. 1015-1028, UNCTAD, 2014, pp. 106-114).

Methodology of the research

Due to the availability of data in a comparative analysis of investment attractiveness of Central and Eastern European countries it has been decided to include the following 17 economies: Albania, Belarus, Bosnia and Herzegovina, Bulgaria, Croatia, Czech Republic, Estonia, Hungary, Latvia, Lithuania, Moldova, Poland, Romania, Russian Federation, Slovak Republic, Slovenia, Ukraine. Remaining the research period is the years 1995-2013 and surveyed materials cover the data of UNCTAD.

Firstly, the inward FDI attraction indexes of CEE countries have been calculated by the authors based on the methodology used by UNCTAD for the period 1995-2013. It was decided to own calculations, as UNCTAD published only these indicators for the years 2000-2011. The inward FDI attraction indexes proposed by UNCTAD's experts rank countries by the FDI they receive in absolute terms and relative to their economic size. It is the average of a country's rankings in FDI inflows and in FDI inflows as a share of GDP. This index according to the specialist working for UNCTAD is more relevant because FDI flows can fluctuate significantly year on year, and direct investment decisions can span more than one year and imply long-term commitments (UNCTAD, 2012, p. 30).

Secondly, we assumed that a progress in the development of new locational determinants of FDI inflow by CEE countries can be observed in the changes of character of their comparative advantages for example thanks to the proxy of merchandise trade specialization index calculated by the UNCTAD secretariat. As it was described, new locational advantages are connected with acquiring knowledge and innovation activity and thus a segmentation criterion of trade structure was chosen the degree of technological sophistication. Using the UNCTAD data in the study taken into account the following groups of products:

1. Primary commodities, precious stones and non-monetary gold (PC).
2. Manufactured goods by degree of manufacturing:

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

- Labor-intensive and resource-intensive manufactures (LRM).
- Low-skill and technology-intensive manufactures (LSM).
- Medium-skill and technology-intensive manufactures (MSM).
- High-skill and technology-intensive manufactures (HSM).

Values of merchandise trade specialization index (TSI) are used to measure the degree of specialization in the production/consumption of goods through trade. It compares the net flow of goods (exports minus imports) to the total flow of goods (exports plus imports). This is also known as normalized trade balance by product. The formula of this index is as follows: $TSI_{ji} = X_{ij} - M_{ij} / X_{ij} + M_{ij}$, where i is product or product groups, j economy, X_{ij} economy's j exports of goods i , M_{ij} economy's j imports of goods i .

The range of values is between -1 and 1, the positive value indicates that an economy has net exports (hence it specializes on the production of that specific product) and negative values means that an economy imports more than it exports (net consumption). This index removes bias of high exports values due to significant re-exports activities, thus it is more suitable to identify real producers than traders (UNCTADstat: <http://unctadstat.unctad.org/TableViewer/summary.aspx>., access data: 10.12.2014).

The values of merchandise trade specialization indexes of CEE countries are presented together with the volumes of inward FDI stocks and inflows expressed in USD at current prices and current exchange rates per capita in 1995-2013. A comparison of variations in the volumes of FDI stocks and inflows per capita shows again, like in the case of inward FDI attraction indexes, the changes in investment attractiveness of CEE countries. In measuring success in attracting FDI by countries using stocks shows long-term commitments of foreign investors, and if policy initiatives to improve FDI attraction have an effect.

Then, it was decided to perform the linear correlation method to verify which export groups in terms of technological sophistication probably stimulated the most FDI inflows to the observed countries of CEE in three periods 1995-2013, 1995-2004 and 2005-2013. As it was above stressed this kind of export structure according to the level of technological sophistication reflects comparative advantages of countries and can stimulate FDI inflows of a specific profile, e.g. strategic assets-seeking FDI or resource-seeking FDI. The observed variables, i.e. the variation in the size of exports groups and FDI inflows, were expressed in USD at current prices and current exchange rates. All included in correlation analysis variables were

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

transformed into natural logarithms. The Pearson's correlation analysis also was accounted for the time delays in which the independent variable being a given export group in year t_0 , is the cause of the emergence of the phenomenon being explained, i.e. it refers to a change of the size of inflow of FDI in year t_{+1} .

**Research results of Central and Eastern European countries
investment attractiveness**

In table 1 are presented the positions of researched countries according to calculated inward FDI attraction indexes obtained first in a group of 17 CEE economies and second in a ranking of 195 countries included in the study. Were also calculated the changes in ranks of surveyed countries for for the whole analyzed period.

In 2013 the first four places in the ranking of CEE countries according to the values of inward FDI attraction indexes occupied the Russian Federation, the Czech Republic, Albania and Belarus. The last positions took Poland, Slovenia, Slovakia and Lithuania. In 1995 first four positions gained Hungary, Slovakia, the Czech Republic and Poland, and the last four Bosnia and Herzegovina, Belarus, Croatia and Bulgaria. Therefore, in the years 1995-2013 Belarus recorded the highest rise in the ranking by 12 positions, and Poland and Slovakia, the biggest drop of 13 places.

In the years 1995-2013 the largest increases in the ranks of CEE countries according to the inward FDI attraction indexes among of all 195 economies experienced Belarus, Bosnia and Herzegovina, and the Russian Federation. In the whole analyzed period the greatest decline recorded Poland, Slovakia and Slovenia. In the first 10 years of the research period, that is 1995-2004, Bosnia and Herzegovina (up 107 ranks), Bulgaria (up 83 ranks) and Romania (up 51 ranks) stimulated the most FDI inflows relative to their economic size. In 1995-2004 the drop in FDI inflows occurred only in the case of Hungary (down 39 ranks), the Czech Republic (down 17 ranks), Slovakia (down 14 ranks), Moldavia (down 13 ranks) and Latvia (down 11 ranks). In the next 9 years, that means 2005-2013, their positions in this respect increased only three countries: Belarus (up 51 ranks), Albania (up 47 ranks) and the Russian Federation (28 ranks). In turn in this period, the greatest decreases of investment attractiveness characterized Poland (down 135 ranks), Slovakia (down 95 ranks), Slovenia (down 80 ranks) and Croatia (down 66 ranks). Moreover, among the 14 CEE countries that have worsened their ranks in the volume of FDI inflows relative to their econom-

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

ic size, the smallest decline in this category has reached Latvia, and it was up to 20 places.

Table 9. The ranking of CEE countries according to inward FDI attraction index, 1995-2013

Source: own calculations, based on: <http://unctadstat.unctad.org/ReportFolders/reportFolders.aspx>. (10.12.2014).

Table 2 presents the sizes of inward FDI stocks and inflows per capita and the values of merchandise trade specialization index for CEE countries in 1995-2013. The biggest success in attracting FDI at a longer time frame in absolute terms gained Estonia, the Czech Republic, Hungary and Slovakia – all these countries obtained FDI stocks per capita higher than 10000 USD in 2013. The smallest long-term commitments of foreign investors occurred in the case of Moldova, Ukraine, Belarus and Albania - all these countries obtained FDI stocks per capita lower than 2000 USD in 2013. The largest increases of FDI stocks per capita in the absolute terms in the researched period recorded again Estonia (16 493 USD), the Czech Republic (12 374 USD), Slovakia (10 674) and Hungary (10 614 USD), and the

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

lowest increases Moldova (1048 USD), Ukraine (1686 USD), Belarus (1785 USD) and Albania (1898 USD).

In the researched period the average FDI inflows to the observed CEE countries were the largest sizes in 2005-2008 – precisely in 2005 446 USD, in 2006 518 USD, in 2007 713 USD, in 2008 652 USD. In 2013 the average FDI inflow per capita to the observed seventeen CEE countries was only 213 USD. In 2013 to the top 5 CEE countries in the size of FDI inflow per capita belonged Estonia, the Russian Federation, the Czech Republic, Latvia and Albania, and among the five countries classified at the lowest positions were Slovenia, Poland, Moldova, Ukraine and Bosnia and Herzegovina. Moreover, in the case of Slovenia and Poland the FDI inflows per capita attained a minus value. In the last five considered years 2009-2013 the largest average FDI inflows per capita occurred in Estonia (964 USD), Hungary (552 USD), the Czech Republic (459 USD), Latvia (373 USD) and the Russian Federation (369 USD), and the smallest in Slovenia (-4 USD), Moldova (63 USD), Bosnia and Herzegovina (96 USD), Ukraine 132 USD) and Romania (153 USD). Thus these sizes of average FDI inflows can indicate which countries' policy initiatives had lately the biggest effect in attracting inward FDI.

Source: <http://unctadstat.unctad.org/ReportFolders/reportFolders.aspx>. (10.12.2014).

Among the observed CEE countries in the case of Albania, Bosnia and Herzegovina, Croatia and Moldova there are no positive values of merchandise trade specialization indexes for all considered groups of products. In the case of Hungary the comparative advantages are just beginning to emerge. Only the Russian Federation among the observed CEE countries specializes in primary commodities, precious stones and non-monetary gold. For this country the positive value of TSI also occurs for low-skill and technology-intensive manufactures. Ukraine specializes only in low-skill and technology-intensive manufactures. Belarus, Bulgaria, Estonia, Latvia, Lithuania and Romania have in fact their comparative advantages only in labor-intensive and resource-intensive manufactures. Among all researched CCE countries the highest degree of specialization in labor-intensive and resource-intensive manufactures occurs in Lithuania. Moreover, only in the case of Lithuania and Poland a comparative advantage in labor-intensive goods has deepened in recent years.

The Czech Republic and Slovakia have their comparative advantages in three product groups, with the highest specialization in medium-skill and technology-intensive manufactures, and significantly improving the situation in high-skill and technology-intensive manufactures. Poland has also a comparative advantage in three product groups, but the highest degree of specialization occurs in labor-intensive and resource-intensive manufactures. Slovenia explicitly loses its advantage in labor-intensive and resource-intensive manufactures, and strengthens its specialization in medium-skill and technology-intensive manufactures. Additionally, in the case of Slovenia are starting to emerge the comparative advantages in low-skill and high skill manufactures.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

As to Poland, it should be noted that in 2013 compared to previous years there was a large decrease in FDI inflow measured the inward FDI attraction index, because in 2012 Poland occupied 98, and in 2011 54 place, in this category, among 195 economies in question. However, does not change the fact that there is currently a deterioration of perceived Poland's investment attractiveness. Unfortunately, the interest in investing in Poland as a TNCs' top prospective host economy, declared by the respondents participating in the research conducted by UNCTAD in the group of 164 companies, is not yet reflected in the volume of FDI inflows (UNCTAD, 2014, p. 28). It can be connected with the negative values of Poland's trade specialization indexes for high-skill and technology-intensive manufactures (see table 2). At the same time, the highest degree of specialization remains in labor-intensive and resource-intensive manufactures. However, this situation does not imply that in comparison to other economies with more resources of cheap labor and less developed, Poland is still competitive in this regard. Therefore, UNCTAD experts emphasize that Poland adopted the "Program to support investments of high importance to the Polish economy for 2011–2020", with the aim of increasing innovation and the competitiveness of the economy by promoting FDI in high-tech sectors. In other words, Poland needs to invest in the development of new locational advantages to increase the inflow of FDI (OECD, 2014, p. 55-64, UNCTAD, 2014, p.113).

Table 3 presents the results of the research obtained from estimating Pearson's linear correlation between considered in this analysis export groups in terms of technological sophistication and FDI inflows to the observed seventeen CEE countries in the years 1995-2013. All correlation coefficients are positive and statistically significant on the level 0.05. The scale of FDI inflows is the strongest positively correlated with an increase in labor-intensive and resource-intensive exports in the whole researched period and in the years 1995-2004. In the period 2004-2014 the correlation relationship was weaker, and the highest value of correlation coefficient occurred for low-skill and technology-intensive manufactures exports. The values of correlation coefficients also indicate that the relationship between FDI inflows and medium-skill and high skills technology-intensive exports has become weaker over time. This may be due to the fact that foreign investors rather are looking for strategic assets in other areas of the world, and the advantage in the labor-intensive industries are currently not as competitive, as compared to the rest of the world, which was described above on the example of Poland.

Research results indicate, therefore, that the investment attractiveness of CEE countries was higher and more stable in the period 1995-2004 than in the years 2005-2013, when took place an explicit decrease in interest of investors in this region of the world. Analysis of changes in the nature of comparative advantages of the concerned CEE countries shows that the reason may be that these countries either do not have a comparative advantage, or lose their comparative advantages in less technologically advanced product groups, not attaining a sufficient degree of specialization in more technologically advanced goods.

Conclusions

Comparing the investment attractiveness of Central and Eastern European countries shows that rather a narrow group of countries attract a greater amount of FDI and many more countries have experienced a decline in FDI. Therefore, the research results allow the conclusion that Central and Eastern Europe reduced its investment attractiveness over the past years, measured both by the inward FDI attraction indexes and the FDI inflows per capita. This means that the majority of Central and Eastern European countries are becoming less successful in attracting FDI, and therefore in shaping the environment in which foreign companies wish to conduct their business.

The reasons can be many and varied depending on the country. First, the strengthening of competition for FDI from Asian countries, especially the

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

Asian Tigers, as the international statistics show. Secondly, the loss by a large part of Central and Eastern European countries of their relative cost advantages towards the rest of the world, without, for example, offering in exchange, locational attractions, are emphasized in this work. These, so called new locational advantages, attracting mainly foreign investment seeking strategic assets that allow achieving higher added value of business activities not only by foreign firms. These new locational advantages also provide a country an opportunity of increasing productivity based on different forms of knowledge development and sharing, as a result of creating infrastructure to facilitate the emergence of knowledge spillovers and their external effects.

The Transmission Mechanism of Unconventional Monetary Policy

JEL Classification: *E42; E52; E58*

Keywords: *unconventional monetary policy; monetary transmission mechanism; central banking; quantitative easing*

Abstract: The implementation of unconventional (nonstandard) monetary policy instruments by the leading central banks at the wake of the financial and economic crisis was the most significant shift in the practice of central banking in the recent years. Evaluation of their effects is not feasible without a thorough recognition of the transmission mechanism of various balance-sheet policies, such as quantitative easing. The transmission channels of a standard interest-rate policy are based on a group of theories that are relatively coherent and well-documented. On the contrary, identification of similar framework for unconventional measures proved to be a complicated task. The aim of this paper is to extract and evaluate the theoretical efficiency of particular channels of unconventional monetary policy. This goal requires references to at least several, to some extent mutually exclusive, theories. It is also inevitable to draw one's attention to the relative significance of identified channels, depending on the nature of used unconventional tools, as well as on reactions of financial institutions and other economic agents to undertaken actions. This paper discusses three broad channel of the unconventional policies transmission mechanism: the signaling channel, the liquidity channel, and the portfolio-balance channel.

Introduction

Intensification of the financial and economic crisis led to unprecedented cuts in interest rates by central banks around the World. However, in the last quarter of 2008 these actions faced three serious obstacles (see Wright, 2012). The first one was the zero lower bound, which caused the inability to cut main interest rates any further, even though the natural interest rate was negative. The second problem arose from a sharp increase in demand for reserves in the financial system, limiting the redistribution of liquidity among financial institutions and making central banks less capable of controlling market interest rates. Finally, due to heavy distortions in monetary transmission mechanism, traditional interest-rate policy led to weak (or even no) reaction of economic agents to monetary impulses. Searching for an alternative or a substitute for traditional monetary policy many central banks chose to try unconventional or non-standard instruments.

The term “unconventional” monetary policy is used to describe a broad set of measures, directed both at financial and macroeconomic stability goals of central banks (compare Borio & Disyatat, 2009). They have been providing funds at longer maturities and use broader lists of accepted eligible collateral. Some of the policies involve changes in either the composition (qualitative easing) or size (quantitative easing) of a central bank’s balance sheet. Qualitative easing often introduces “unconventional” (i.e. asset-backed securities) assets that replace “conventional” ones. Since the failure of Lehman Brothers, however, both approaches have been used simultaneously and changes have been denoted both in size and structure of central banks’ balance sheets. Moreover, there has been a significant change in the way operations were carried by central banks and announced to market participant, such as forward guidance.

Implementation of unconventional policies also started a fierce debate concerning their numerous effects: direct and indirect, intended and unintended, both domestically and internationally (see Krishnamurty & Vissing-Jorgensen, 2011). The lack of precise evaluation of these effects may be attributed to the insufficiency of empirical work in the field. The available empirical material is relatively short period of use of such tools as quantitative easing. What is more, numerous spillovers from the use of unconventional tools make it hard to isolate specific impact of certain policies. Yet this scarce evidence also stems from the limitations of standard macroeconomic model and its theoretical predictions, particularly an incomplete analysis of the transmission mechanism of non-standard actions.

The aim of this paper is to identify and evaluate the channels of the transmission mechanism of unconventional monetary policy. The next section briefly describes the methodology of the research. Then I proceed to specific channels of transmission mechanism: the signaling channel, the liquidity channel, and the portfolio-balance channel. The last section concludes and points out several areas for the future research

Methodology of the research

In order to outline the transmission mechanism of unconventional monetary policy, this study makes use of a comprehensive literature research. Transmission mechanism channels of conventional monetary policy are a broad, but a relatively well-investigated group of concepts allowing to have a better understanding of effects of interest rate changes in different economy sectors. Due to lack of thorough research in the relevant area, preparing a corresponding list for unconventional monetary policy seems to be a complicated task. The classic model gives only a narrow explanation of the effects of certain policy, referring to economic agents' expectations only. The attention is drawn to the differences between the theoretical assumptions of the model and the empirical results (Farmer 2012). The number of transmission channels that are used in different studies varies between two (Bernanke & Reinhart, 2004) and seven (Krishnamurty & Vissing-Jorgensen, 2011), depending on the author's approach. Additional difficulties arise due to high level of uncertainty in setting and measuring effects of different unconventional tools used simultaneously, recognizing their implications and presenting the possible scenarios of a reaction of a central bank. The attempt to isolate and evaluate channels of the transmission mechanism is of curtail importance. Not only allows it to define the recent outcomes, but also to evaluate the potential effects of the strategies of the exiting unconventional monetary policy.

Since there is no single coherent theory that allows to explain in-depth functioning of the transmission mechanism of unconventional monetary policy, this study analyzes different attempts to explain effects of non-standard tools and classifies them as channels of the mechanism. The paper involves various critical references to theoretical and empirical studies. The conducted literature study makes use mostly of the recent literature, however, when needed, certain references to fundamental works in the field are made. The analysis of each channel is divided into three parts. The first one sets-up the underlying theories of a channel. The second part explains the

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

details of particular effects of monetary impulses. The third one provides an exemplification of how unconventional policies work through a channel works, as well as outlines condition of their effectiveness.

The Signaling Channel

The first approach to be discussed in the matter of explaining transmission of unconventional monetary policy's actions is the signaling channel (Bauer & Rudebusch, 2013), also called the inflation risk channel (Krishnamurty & Vissing-Jorgensen, 2011). The analysis of transmission mechanism starts with the description of this channel, as from theoretical perspective, it is based on mainstream economic models. These models put a strong emphasis on inflation expectations in effective realization of monetary policy. And so signalling channel, in its core assumptions, is similar to the expectation channel of interest rate policy; the main difference being the actions or communicates of the central bank triggering it that are far beyond the standard way of conducting monetary policy (Cecioni et al., 2011).

The idea behind functioning of signalling channel is so called neutrality proposition introduced by Wallace (1981), which states that the way of conducting the open market operations by the central bank has no impact on the dynamics of main macroeconomic indicators¹. The hypothesis was formulated with the assumption of full rationality of agents, as well as completeness of financial markets. However, Curdia and Woodford (2010) claim that formulating it requires only two key assumptions:

- market value of assets depends only on previous cash flows – they not necessary have to be absolute substitutes, but the only differentiating criterion is their risk factor,
- all the investors can buy the same amount of assets at the same price; the only limitation being their budget constraints.

From the perspective of unconventional monetary policy, and balance-sheet policy in particular, the irrelevance proposition, derived from Wallace hypothesis, seems to be of crucial importance (Eggertsson & Woodford, 2003). According to this theorem, not only the operations of a central bank, but also the relative share of different assets in its balance, have no impact

¹ The Wallace neutrality reveals significant ties with the Modigliani-Miller theorem, that states that the capital structure of a company is irrelevant for the value of this firm.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

on the general equilibrium of an economy. There are two complimentary ways to explain this phenomena.

First of all, having two beforehand-mentioned assumptions fulfilled, calculating the current market price of each asset is based on pricing kernel, which can be understood as a discount factor of future cash flows generated by this asset. The pricing depends on the expected value of the marginal utility of income of a household, which is a random variable. The use unconventional monetary policy (e.g. qualitative easing) influences only shifts in distribution of available assets between a central bank and a private sector. However, it does not change the availability of stock to consume in the future. And so the assets pricing done by a household as well as its level of consumption is not changed.

On the other hand, if we assume that agents treat the balance of a central bank as a part of the general balance of a public sector (central bank and government), applying unconventional monetary policy will not lead to the “removal” of risk of certain assets, but rather to its transfer from the balance of private sector to the public sector. Having in mind that the balance of the public sector is protected by the tax income from the private sector, the rational agents will follow the Ricardian equivalence. The optimal choice of a household will be affected by the wish to protect future losses connected to higher taxation (the transfer of income). If the central bank buys certain assets, households will change their financial portfolio in order to neutralize its behaviour and keep the future income on the unchanged level.

Accepting the thesis on irrelevance of central bank does not necessarily mean that monetary policy has no impact on the on-going economic processes. The only thing is that the operations involving assets flow as well as expanding the monetary base will not be effective in the situation of liquidity trap. The temporal rigidities of prices and wages implies that a central bank has a possibility to affect the size of inflationary expectations, and indirectly on the deviation of the interest rate of a central bank (adjusted with the current inflation rate) from the natural interest rate, the price level and the size of the demand gap. Therefore, the signalling channel includes the following phenomena (Bauer & Rudebusch, 2013):

- stimulation of inflationary expectations,
- fall of the real interest rates,
- changes in the term structure of market interest rates, particularly the fall of long-term interest rates,
- increase in consumption, investments and the overall demand.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

It is commonly assumed that using the signalling channel in the situation of zero interest rates comes from the seminal work of Krugman (1998). The recommendation he formulated might have seemed provocative, as it included a central bank openly supporting the inflationary processes' escalation². Later on it was wildly commented within the formal models of Reifschneider and Williams (2000) or Eggerston and Woodford (2003).

The effectiveness of transmission of the monetary stimulus through the signalling channel is almost fully based on the reliability of a central bank, the appropriate communication of its intentions and the type of inflationary policy. In the situation when a central bank does not have a sufficient reputation, introducing the optimal monetary policy might be impossible. The realisation of the previous commitments might be also interrupted by the strong and persistent shocks that influence inflation but stay beyond the control of monetary authorities. Partial solution to the this problem is the complementary applying of the different unconventional tool. The changes of the structure or of the size of the balance may lead to the "strengthening" the effects of commitment on the expectations in the following ways (Lenza et al., 2010):

- increasing the power of commitments to preserve the monetary expansion for a longer time,
- causing fall in risk premium component of market interest rates,
- causing direct decrease of the of bonds and securities yields.

Applying the unconventional assets of the high value lowers also the probability of the quick rise of the interest rates, which would later lead to some financial losses of a central bank.

The way the signalling channel functions implies that the stronger effects in terms of economic activity will be caused by the unconventional tools of the wide scope and the ones requiring the strong involvement of a central bank. Among all, one should mention the instruments that require buying assets with the long-term maturity, which affects the flattening of the yield curves. The high effectiveness will be also a feature of the tools requiring future reinvestments of income from the current assets as well as of the "pure" form of quantitative easing, which includes buying bonds and securities as a point of reference to other values.

The idea of the signalling channel has been exposed to a strong criticism, mainly because of the derived conclusions, but also because of the

² In the exact words of Krugman (1998, p. 161), a central bank should be "committed to be irresponsible".

theoretical background. According to some researchers, this way of explaining the effects of unconventional tools is far too narrow and it does not allow to capture its actual, even temporal, consequences in terms of market value of the assets or the cost of gaining the capital (Joyce & Tong, 2012). The objections mainly point out that the irrelevance theorem does not hold if one allows for a slight modification of its assumptions. There are certain non-pecuniary factors influencing risk calculation (such as agents' sentiments) which may boost demand for safe asset during financial crises (Gagnon et al., 2011). Some of the author, for instance Farmer (2012), acknowledge the theoretical construction behind the signaling channel, yet indicate its limited significance in practice.

As a results of this critique, recent studies interpret the signaling channels in a broader way than the standard model. In particular, the assumption of financial markets efficiency is repealed. This leads to a possibility to distinguish the so-called announcement effects, capturing the direct impact of new information on unconventional actions on actions of market participants (Gagnon et al., 2011; Szczerbowicz, 2014). Among these effects are not only shifts in inflation expectations, but also other consequences in markets segments in which unconventional tools are (or will be) implemented (e.g. increased liquidity or trade volumes).

The Liquidity Channel

The second channel of the transmission mechanism of unconventional monetary policy is the liquidity channel (Bowdler & Radia, 2012), sometimes referred to as the bank funding channel (Joyce & Tong, 2012). According to the studies supporting this view, the effects of unconventional tools should be mainly view through the increase in liabilities of a central bank and reserves supply. Such policies are thus bound to improve balances of financial institutions and increase an overall availability of external financing to economic agents.

Historically, the first theoretical approach that allows to explain the functioning of liquidity channel is monetarism. One of the seminal works in this area is the influential paper by Brunner and Meltzer (1968). The authors analyzed several examples of changes in the demand for money under the liquidity trap and rejected the hypothesis of the complete ineffectiveness of monetary policy to overcome the trap. They found out, however, that the lower bound of interest rates is just a kind of an "institutional barrier", and not the effect of the infinite money demand. Consequently, chang-

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

es in the official short-term interest rate (and also of some market interest rates) do not always properly indicate whether monetary policy is expansive or not. What is more, considering short-term interest rate as a first “chain” in the monetary transmission mechanism is often insufficient. Instead, they propose a very broad concept of this mechanism, in particular they suggest that all adjustments of relative market prices could be seen as responses to monetary impulses (shocks) (Meltzer, 2001).

The importance of the liquidity channel, according to the monetarist school, stems from the fundamental differences between the reserve money and other market assets. Due to the fact that agents use money as a store of value, it is considered by financial institutions as a safe asset when compared to more risky securities. Particularly during financial crises, when an average riskiness of other assets increases, the demand function of real money balances must have, at least asymptotically, a finite value. If one assumes, that the demand is a positive function of real transaction volume, and a negative function of an opportunity cost of holding money, then an increase in the nominal money supply may lead to a decrease in yields of securities held by financial institutions.

Consequently, the effects of unconventional monetary policies depend on shifts in a central bank’s liabilities, and an increased monetary base should induce changes in broader monetary aggregates, even under the zero lower bound. The way unconventional monetary shocks transmit to the real economy is yet independent on assets in a central bank’s balance sheet, including a structure of assets bought in order to increase the supply of money. Researchers that currently use this approach in empirical studies, suggests a possible way to use the liquidity channel in order to improve conditions in financial systems, for instance during the periods of a sudden increase in money market interest rates. The effects of unconventional actions may cause a decline in liquidity premium components of interest rates, as they facilitate conversion of securities into money (Gagnon et al., 2010). Increased level of liquidity may then prevent commercial banks from credit rationing or fire-sales of assets, what eventually leads to higher aggregate consumption expenditures and investment.

An alternative theoretical explanation for the liquidity channel of unconventional monetary policy can be derived from the flow-of-funds class of models, which are mainly used for the national income accounting. Such an example is provided by the model of Cobham and Kang (2012), that captures and evaluates the effects of quantitative easing. This simple analytical scheme is based on relations among the basic sectors of the econo-

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

my, represented as flows changing relative asset and liabilities positions through the modification of mutual financial claims. The flow-of-funds model comprising of such agents, as a central bank, a government, and financial and non-financial sectors can be built in a matrix form. Consecutive columns may be interpreted as budget constraints of each sector, while rows represent balances of supply and demand on financial claims, such as a financial deficit of government and private sector, bank deposits and securities.

The analytical framework of the flow of funds model allows considering the impact of monetary policy and the economic shocks on the changes of high-powered money, as well as the money supply, defined as a sum of changes in the amount of cash and the deposits on demand ($\Delta M_S = \Delta C + \Delta D$). The traditional monetary policy, based on the open market operations, will lead to the excessive liability of commercial banks ($-\Delta CB$) as well as the increase of reserve money (ΔR), and as a result the rise of a monetary base ($\Delta H = \Delta C + \Delta R$). The final result of those changes on the money supply will depend on the endogenous mechanism of credit creation in the banking system (Table 1).

Table 1. The effects of quantitative easing in the flow-of-funds matrix

	Central bank	Government	Financial sector	Non-financial sector
Financial deficit	–	$G - T$	–	$I - S$
Bank deposits	–	–	$-\Delta D$	ΔD
Other liabilities	–	–	$-\Delta ND$	ΔND
Monetary base	$-\Delta H$	–	ΔR	ΔC
Government bonds	ΔGD_{cb}	$-\Delta GD$	ΔGD_f	ΔGD_{nf}
Central bank loans	ΔCB	–	$-\Delta CB$	–
Private sector loans	–	–	ΔK	$-\Delta K$

Note: positive values of flows denotes changes in assets, while negative values denote changes in liabilities of sectors;; G i T – government expenditures and taxes, D i ND – deposits and other liabilities of commercial banks, H – monetary base, including reserves (R) and cash (C), GD – government bonds, including bonds held by the central bank (GD_{cb}), by the financial sector (GD_f) and by the non-financial sector (GD_{nf}), CB – central bank operations, K – loans by financial sector.

Source: Cobham & Kang (2012, p. 56).

When the economy is hit by a financial crisis, the financial sector cuts down flow of loans to the non-financial sector (ΔK), what causes an equivalent decrease in deposits between sectors. As a result, despite any changes in in the monetary base (ΔH), market participants are subject to an adverse money shock, ($\Delta M_S < 0$), which slows down investment activities of com-

panies. The limits of conventional interest-rate policy push the central bank towards unconventional actions, which are narrowed down in the model to purchase of government bonds from the non-financial sector by the central bank ($\Delta GD_{cb} > 0$; $\Delta GD_{nf} < 0$). A decrease in the value of bond held by this sector lead to an increase in demand for deposits in commercial banks (ΔD). On the other hand, an increase in government bonds held by the central bank commercial banks, along with an increase in commercial bank liabilities, requires an equivalent flow of reserves (ΔR). If the above assumptions are met, quantitative easing leads both to an increase in the monetary base, as well as in the broader supply of money ($\Delta M_S > 0$). The liquidity channel of unconventional monetary policy can be thus perceived as a provision of a “liquidity buffer” by a central bank, which facilitates adjustments after financial crises.

The relative importance of the signaling channel is proportional to the kind of reaction of the financial system induced by the use of unconventional policies. This reaction, in turn, relies on the following factors:

- a degree in which money is exogenous to real economic activity,
- a value of money multipliers,
- a degree of an overall indebtedness and a pace of deleveraging in the economy.

In order to be effective, unconventional measure must, in accordance with the liquidity channel, facilitate available liquidity (reserves) to financial institutions. The examples of such measures involve long-term open market operations and enhanced liquidity support to certain segments of markets.

The Portfolio-Balance Channel

The third channel of the transmission mechanism of unconventional monetary policy is the portfolio-balance channel. The idea behind this channel relies on changes in the overall value and composition of a central bank’s assets, and their impact on decisions of economic agents. As a consequence, this channel is also named in the literature as the portfolio rebalance channel (Cecioni et al., 2011; Bowdler & Radia, 2012) or portfolio substitution channel (Joyce & Tong, 2012). Conceptually, this channel may be compared, too some extend, to the wealth effects, balance channel and risk-taking channel of interest-rate policy.

The theoretical basis of the portfolio-balance channel is the preferred habitat theory, which received some attention over the past decades, yet is

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

still considered as heterodox. Its origins may be tracked back to works of Tobin (1969), who proved that an average yield and risk factors specific to a particular class of assets are dependent on the relative market supply of these assets. Unlike the standard asset-pricing model, in which demand curves of financial assets are perfectly elastic, this theory assumes that heterogeneous groups of market participants undertake their investment choices only in a particular segment of the market. Their so-called “habitat” depends on indifference curves of market agents regarding both an expected rate of return and risk of a specific asset class. Latest models building on this theory follow this assumption by allowing agents to choose only a limited segment of markets regarding the time structure of asset (a certain segment of a yield curve) (Vayanos & Vila, 2009). For instance, some of the agents may have preferences for particularly long maturities, that would match the structure of their liabilities and allow them to solve the so-called maturity mismatch problem. Consequently, market assets are not considered perfect substitutes because of income they generate, but due to factors connected with their maturity.

The assumption of an imperfect asset substitution and market segmentation change the way that a central bank’s purchases of assets influence portfolios of market agents. When a central bank starts buying a chosen class of assets, their market availability diminished, due to the so-called local supply effect (Bowdler & Radia, 2012). At the same time economic agent re-balance their portfolios in order to remain within a specific segment of the market. The process of quantitative or qualitative easing will then lead to an increase in prices of assets bought by a central bank. These price adjustments will depend on shifts in private sector’s portfolios. Unlike the signaling channel, which emphasized the impact of unconventional tools on the risk-free interest rate, asset substitution will influence other component of market interest rates, such as (Krishnamurty & Vissing-Jorgensen, 2011):

- term premium, proportional to the maturity date of an asset,
- default premium, connected to the evaluation of issuer’s default risk.

The decrease of these components may further cause an overall fall in various interest rates, increase the availability of loans to households and corporations, and boost consumption and investment. Rising prices of asset may, on the other hand, start balance-sheet and wealth effects, and eventually stimulate aggregate demand.

Recent studies on the transmission mechanism of unconventional monetary policy try to incorporate the portfolio-balance channel into and the

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

preferred-habitat theory into the standard macroeconomic model. A significant contribution in this field was made by Farmer (2012). Farmer used a two-period general equilibrium model with rational expectation, and supplemented this framework by adding several assumption. Most importantly, the model incorporates a few different economic agents, one of which has only a restricted access to financial markets. In the first period, entitled agents buy or sell two types of financial assets. In the second period, they receive corresponding returns, which are subject to an extrinsic uncertainty, impossible to foresee in the first period, that changes relative prices of both assets. These effects are then transmitted to agents' real income, labor supply, and consumption.

Such a model makes it possible to compare two different cases: when a central bank remains passive, and when it uses qualitative easing, "replacing" agents that are not entitled to participate in financial transactions. Due to the heterogeneity of agents, a central bank's actions affect market prices of securities. Indirectly, qualitative easing leads to the redistribution of assets among agents, as well as transfers to market participants characterized by higher propensities to consume. Based on this results, Farmer (2012) draws strong a conclusions regarding the portfolio-balance channel. He proves that unconventional monetary policy can be Pareto-improving, since it reduces the overall risk in the economy. What is more, qualitative easing can be implemented in an optimal way, when a central bank carefully choses its portfolio this policy may be self-financed and bears no potential costs for taxpayers.

An alternative approach to the portfolio-balance channel was introduced by B. Friedman (2013) in his "post-crisis" interpretation of the New Keynesian model. Friedman addresses the problem of the effects of unconventional policies by incorporating into the model two different interest rates. Next to the official interest rate set by a central bank, he introduces market interest rate, which is a basis of consumption and investment decisions in the economy. This, in turn, allows to reject the assumption that all assets are perfect substitutes, and incorporate the preferred habitat theory in the model. The key question concern factors influencing the market interest rate. Friedman assumes that the market rate is a function of the official rate, and its expected future path, as well as the ratio of risky assets to all assets. The higher the relative supply of risky assets in the economy, the higher the market interest rate. Unconventional monetary policy in this model can be understood as a process of decreasing the local supply of risky assets and transfer of risk to a central bank's balance sheet. Consequently, non-

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

standard programs, such as quantitative easing can be used as a substitute to interest-rate policy.

A relative meaning of the portfolio-balance channel in the entire transmission mechanism of unconventional policy can be influenced by many properties of financial markets, as well as a central bank's decisions. Among the most important factor one should point out the following (Bowdler & Radia, 2012; Dahlhaus, 2014):

- accurate identification of dysfunctional market segments by a central bank,
- relative financial strength of a central bank to market, delimiting the upper limit of risk transfer from private sector to central bank's balance sheet,
- degree of substitutability of assets,
- average pace of portfolios rebalancing,
- response of prices and yields of assets to changes in their relative supply.

Qualitative easing, which involves outright purchases of chosen classes of assets, is undoubtedly among the most effective unconventional tools, when assessed through the lens of the portfolio-balance channel. The non-standard operation in the segments of long-term securities may also induce rapid changes in private sector's balance sheets, and shift of demand to other, more risky assets.

Conclusions

The aim of this paper was to identify and evaluate the theoretical framework of the transmission mechanism of unconventional monetary policy. The analysis covered three broad channels of monetary impulses generated by such policies, as quantitative or qualitative easing. The signaling channel, derived from the canonical model of the new neoclassical synthesis, underlines the importance of the so-called neutrality of central bank's balance sheet. This channel works mainly through stimulation of inflationary expectations and the subsequent the fall of long-term interest rates. Monetarist theory and the class of flow of funds models allowed to identify a liquidity channel, which effects rely on changes in central bank's liabilities. The liquidity channel stresses the importance of non-standard tools used by a central bank, which facilitate adjustments after financial crises. Finally, the portfolio channel is grounded in the theories of imperfect substitutability of assets, and explains the effects of shifts in value and

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

structure of central bank's assets on decisions of economic agents. The overall impact of unconventional instruments is dependent on a decrease in various market interest rates, as well as increase the availability of loans to households and corporations.

Numerous unintended consequence of unconventional policies lead to the conclusion that their theoretical models are still not sufficient to fully explain complex impact of changes in central banks' balance sheets on financial markets and economies. In particular, there is an urgent need for a comprehensive theoretical model of international spillover effects of unconventional tools, that will allow to extract the effects of policies undertaken by the main central banks for the emerging economies, such as China. Another important area of future research is the exit strategy from the unconventional measures which, except for the case of the Bank of Japan, has no precedent.

State Aid and Competitiveness of the Hard Coal Mining Industry in the European Union*

JEL Classification: *D22; E65; F30; F60*

Keywords: *state aid; competitiveness of industries; hard coal mining industry in Poland and the EU; Polish mining enterprises*

Abstract: The hard coal mining industry in the European Union (EU) is in decline, mostly due to a lack of price competitiveness. It is maintained, to a great extent, by state aid; a key objective of the industry's existence is to provide energy security and guarantee employment in the mining regions. In Poland, the hard coal mining industry is currently undergoing a serious crisis that threatens the two largest mining enterprises with bankruptcy. In addition, due to the European Union's restrictions concerning the circumstances of granting state aid, these enterprises cannot count on the financial support for the repair restructuring that they used on a large scale until 2011. Therefore, in this article, the main objective is to determine the influence of state aid on the competitiveness of the hard coal mining industry in 12 countries of the EU, including Poland in specific. In order to achieve the stated objective, the article is divided into three parts. The first part consists of a literature review and legal regulations that are related to state aid for the hard coal mining industry in the EU are presented. The second part identifies the amount of state aid for the mining industry in the examined countries. Next, the influence of the state aid on the economic-financial conditions and competitiveness of the industry in the examined countries is examined. The third assesses the finan-

cial results of 24 Polish hard coal mines. The data of Eurostat and EURACOAL were used in the research. Furthermore, the primary data from the Polish mines of power hard coal were also used. The research methodology includes the indicators from the area of effectiveness and productivity assessment, as well as production quality assessment in the mining industry. The research results make it possible to extend knowledge in the range of the influence of the state on the competitiveness of the traditional industries and their restructuring.

Introduction

The role of the state in the theory of economy may be analyzed and evaluated within the frames of two main research trends that differ in their approach to the effectiveness of influence of the state on real values in economy. Accordingly, in the neoclassical trend that was derived from the classical school, a minimal range of state intervention in the economy is advised—it is reduced to providing law obedience and security, as well as to prevent monopoly (Stankiewicz, 2000, pp. 163-164; Smandek, 1993, pp. 9). In turn, in Keynesian trend, state intervention is acceptable in the market mechanism, due to its disability and lack of optimality in business and household decisions in a short-term period (Wojtyna, 2000, pp. 70-76; Sychalski, 2002, pp. 2502-255; Zieliński, 2008, pp. 20-27).

In this article, an attempt is made to conduct an effectiveness assessment of state intervention in the industrial restructuring of hard coal mining in the EU. In many contemporary types of research on restructuring efficiency and effectiveness in state-owned sectors, it is emphasised that the restructuring objectives are more often fully achieved in case of private enterprises. State ownership disturbs the process of resources allocation, slows down management initiatives and delays investment decisions, which makes proper functioning impossible in a liberalised and competitive economic environment (Kam et al., 2008, pp. 567-579; Apostolov, 2013, pp. 680-691). The restructuring process of state-owned enterprises is also disrupted for political reasons of the decisions made (Bhattacharyya, 2007, pp. 317-332; Apostolov, 2011, pp. 124-134).

In the period analyzed in the article, which encompasses the years 2000-2012, the hard coal mining industry in the EU was systematically subsidised within the frames of EU Council Regulation no. 1407/2002 on 23 July 2002, which pertains to state aid for the coal industry. According to the regulation, retaining domestic energy security justified state aid granting for unprofitable hard coal mines (Olkuski, 2011, pp. 42-45). However, financial support for the mining industry concerned a wide subject range,

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

which included aid for the closure of unprofitable mines, operating aid, investment aid (Michalak, 2012, pp. 11-22; Michalak, 2012, pp. 267-276) and aid for extraordinary costs that were inherited and connected to sector restructuring (Paszczka & Białas, 2009, pp. 135-156).

The state aid categories for hard coal mining that are listed above were limited in the decision of the European Commission on state aid to facilitate the closure of uncompetitive coal mines (2010/787/UE). According to the decision, these days state aid may only be granted for:

- The costs of closing unprofitable mines, also including current production losses, provided that the mines will have been finally closed down by 31 December 2018,
- extraordinary costs financed until the end of 2026, mostly connected with social costs (pensions and employee benefits for dismissed staff) and technical ones (securing infrastructure of liquidated mines).

Consequently, support for initial investment and state aid without time limits were dropped, which hinders the domestic initiatives concerning the improvement of sector's competitiveness (Białas, 2011, pp. 7-28; Górczyńska & Szwejca, 2012, pp. 23-29).

Methodology of the research

The main purpose of the article and the research that was conducted was to perform the assessment and comparative analysis of the results of the hard coal mining industry in the countries of the EU in which hard coal mining was subsidised by public resources (Anderson, 1995, pp. 485-496; Frondel et al., 2007, pp. 3807-3814). The author of the article is also searching for an answer to the following research questions:

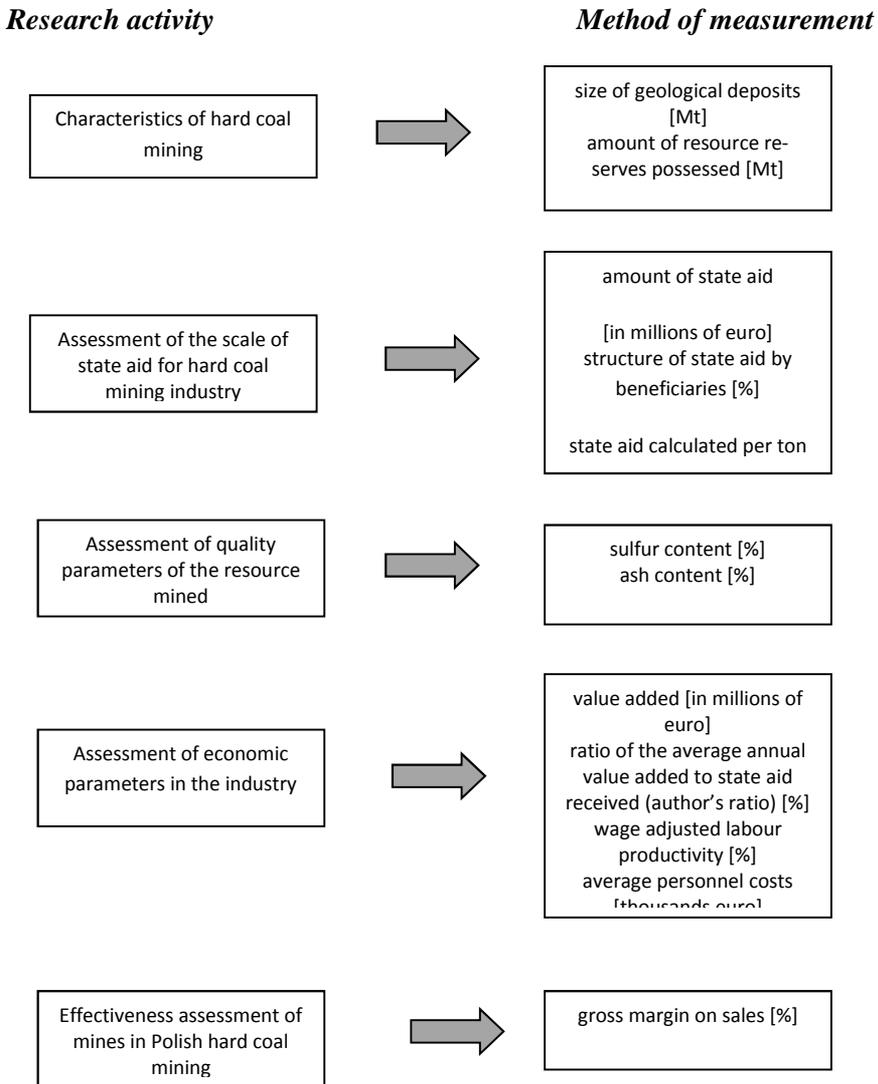

- Which countries, in the years 2000-2012, granted the highest amounts of state aid to the hard coal mining industry? Has such a move found its reflection in the economic and quality results of the examined industries?
- What are the development perspectives of the Polish hard coal mining in the light of the current EU regulations concerning state aid for the industry and in the context of the current economic situation of the Polish mines?

Because of two types of threads in the questions above, the research part of the article was divided into two stages. The first stage includes a comparative analysis of state aid granted for the mining industry from public resources. The second stage encompasses the results of measurement and analysis of effectiveness in 24 Polish hard coal mines from 2005-2012,

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

together with the assessment of the perspectives of their further functioning in the structures of two largest state-owned mining enterprises.

Figure 1. Ratios used in the research methodology

Source: own work.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

The research methodology is of interdisciplinary character and contains the ratios typical for economic analysis and for the assessment of hard coal reserves and quality in the mining industry. The detailed information on the universal and special ratios that were used—constructed for the purpose of the research conducted—is presented in figure 1.

In the research, there are statistical data that come from Eurostat and Euracoal databases, as well as data obtained during the author's research carried out in 24 hard coal mines that belong to the two largest Polish mining enterprises.

State aid for the hard coal mining industry in the European Union

The hard coal mining industry in the EU is an industry that is systematically subsidised by state funds, and economic and social-political priorities have been competing with one other for many years in the industry. On the one hand, it is an industry that is characterised by low and decreasing price competitiveness, thus making efficient competitive struggle impossible. On the other hand, it is an industry that provides thousands of jobs in mining regions and/or additionally guarantees energy security (Miller, 2011, pp. 1-51). The characteristics of the working and potential coal deposits (reserves), together with the number of people employed in the mining industry, in the examined countries of the EU is presented in table 1.

The results from the data included in table 1 indicate that Poland possesses largest deposits of hard coal. Significant but smaller hard coal deposits are also found in Germany and Great Britain. In turn, the largest lignite deposits are localised in Poland, Germany and Hungary. Lignite is a kind of fuel that Germany, Poland and Greece (Kavouridis, 2008, pp. 1257-1272; Roch, 2009, pp. 857-867) have at their disposal to the largest potential extent.

Polish hard coal mining employs 113 thousand people, which is a record value in the listing presented. In Germany, the mining enterprises employ about 34 thousand workers and, in Great Britain (Lorenz, 2009), almost 6 thousand people. In connection with the above, the greatest social threat would be even a partial liquidation of hard coal mining in Poland within the Upper Silesian Coal Basin (Zieliński, 2013, pp. 137-143). It is worth mentioning that, in Germany and Great Britain, employment in the hard coal mining industry has been systematically reduced in the last few years, just as in France and Spain (Fernández, 2000, pp. 537-547), which are the countries that formerly lead the production of hard coal in Europe.

The countries listed in table 1 may use state aid as a matter of law in force in EU. The value of state aid granted from 2000-2012 is presented in table 2 and the structure in division into the particular countries is listed in table 3.

¹ It is the first product of coal transformation into bituminous coal. It is characterised by low calorific value and contains about 60-65% of coal. In different classifications, lignite is often called brown coal.

² Coal of calorific value between 7.5-21 MJ/kg.

³ Coal of calorific value between 16-29 MJ/kg.

⁴ The most transformed form of coal of the highest calorific value between 30-33 MJ/kg.

The data from tables 2 and 3 show that the greatest beneficiaries of state aid for hard coal mining were Germany, Spain (Rabanal, 2009, pp. 4373-4378; Zafrilla, 2014, pp. 715-722) and Poland from 2000-2012 with a share in total aid, respectively, at 51.08%, 29.22% and 10.51%. Furthermore, the period of the most intensive aid for Spanish mining was from 2000-2002; in German mining, it encompassed the years 2001-2003 and in Polish mining it included the years 2002-2004. In all of these cases, these were the years of dynamic repair restructuring in this industry (fig.2).

After the year 2003, one may also observe the value decrease of total aid for mining in EU in all of the examined countries (figure 3). It was caused by a reduction of aid for major beneficiaries, the completion of the most important restructuring activities and, finally, the tightening the conditions of granting state aid for mining industry in the year 2010, due to a lack of competitiveness improvement of unprofitable hard coal mines despite state support and violation the rules of free-market competition at the same time (Caputa, 2012, pp. 49-71; Szwajca, 2012, pp. 18-20).

In order to perform a deeper analysis of the range of state aid for the hard coal mining industry and to take into account the differences in the

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

resource and excavation potential of the examined countries, the value of state aid was calculated per ton of the resource mined in the particular country. The results of the calculation are presented in table 4.

The objectified values of state aid only partially confirm the previous conclusions concerning its largest beneficiaries; in a relative approach, they were still Spain (from 48 euro/ton to 292 euro/ton) and Germany (from 7 euro/ton to 38 euro/ton). However, Poland, due to the large range of excavation in the examined group, obtained subsidy for one ton in the amount of 0.67 euro to 34 euro. That means that Slovenia had a similar level of state aid from 0.43 euro/ton to 40 euro/ton. It is also worth stressing that France obtained the highest state aid (from 305 euro/ton to 1170 euro/ton) from 2000-2004; however, these were the means fully allocated for the total liquidation of hard coal mining in this country.

**Qualitative and economic effects of state aid for hard coal mining
in the European Union**

Knowing the scope of state aid for hard coal mining in the examined EU countries, it is worth looking into the quality and economic results attained in this business within the last five years. This is because both qualitative and economic parameters enable the analysis of competitiveness of the examined industry in the particular countries. The basic coal quality assessment parameters are consecutively presented in table 5. The first is the lower heating value, the so-called calorific value. This is the heat of combustion reduced by the heat of vaporization of the water formed during coal combustion, as well as created by the hydrogen contained in coal. The calorific value measurement unit is kJ/kg or MJ/kg (kilojoules or megajoules per kilogram). A higher coal heating value indicates greater usefulness and effectiveness as an energy resource.

The next important quality assessment parameter for coal as an energy resource is the sulfur content in coal, which fluctuates from a few tenths of a percent to 4%. The higher the sulfur content, the worse the coal quality. In the EU, in which great importance is currently attached to the clean production of electricity, this parameter is particularly important, due to the continuous tightening of emission restrictions concerning, among others, sulfur compounds.

Ash content, the next coal quality parameter, is perceived similarly. Ash content constitutes ash residue after the roasting of coal. It enables the determination of the coal purity category. There are 5 basic categories:

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

- high-purity coal with an ash content of less than 10%,
- medium-purity coal with an ash content from 10 to 20%,
- low-purity coal with an ash content from 20 to 30%,
- very low-purity coal with an ash content from 30 to 50%,
- coal slate with an ash content from 50 to 80%.

The coal of the highest quality is characterised by the lowest ash content.

According to the data presented in table 5, lignite mined in the Czech Republic, Bulgaria and Germany is specific for the highest calorific value. In the case of hard coal, the highest heating value is presented by coal mined in the Czech Republic, Germany and Great Britain. The average calorific value of hard coal in Spain, one of the leading beneficiaries of state aid, is very low, at just 18 231 kJ. Poland, with heating value ranging from 21 000 kJ to 28 000 kJ, is located in the middle of the ranking; nevertheless, it should be noted that, in a situation of dropping coal prices on the European market as well as rising expectations in terms of raw materials' quality in the power industry, the average level of calorific value at a high price does not guarantee demand for Polish mining production.

On the other hand, lignite with the lowest sulfur content is mined in Greece, Poland and Slovenia. In the case of hard coal, Czech, British and Polish coal has the lowest sulfur content. The worst quality parameters in terms of sulfur content are characterised by Bulgarian, Romanian and German coal.

In terms of ash content in lignite, the best results are achieved by Poland, Slovenia and Bulgaria (Papagiannis et al., 2014, pp. 414-424). In the case of hard coal, the lowest ash content is contained in Czech, British and German coal. Polish hard coal has average ash content which, in combination with average sulfur content and calorific value, definitely does not favor the competitiveness of the Polish raw materials on the European market.

Summing up the assessment results of the quality of lignite, it should be stated that the best quality parameters are presented by Czech and Slovenian lignite. On the other hand, the best-quality hard coal is mined in the Czech Republic, Great Britain and Germany. Among these countries, substantial state aid has been transferred to the German, British and Slovenian mining industry. Czech mining has not been subsidised in such a wide range, and yet it achieves very good quality parameters.

Source: own work based on the EURACOAL data, *Coal industry across Europe*, 5th Edition 2013.

In table 6, there are parameters characterizing the economic results of hard coal mining in the examined countries. Firstly, in terms of value added, the best results were achieved by the Czech Republic and Great Britain, where the average value added from 2008-2012 exceeded almost seventyfold and sixtyfold respectively the value of state aid transferred to hard coal mining from 2000 to 2012. Good results in this area were also achieved by Greece and Bulgaria. Poland, with an outcome at the level of 80%, is placed in the final section of the ranking.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

On the other hand, the best ratio of value added to wages is achieved by Great Britain, Romania and Hungary. The last two of these countries owe their high productivity index value above all to low wages.

Source: Eurostat, *Structural Business Statistics*.

⁵ Value added represents the difference between the value of what is produced and intermediate consumption entering the production, less subsidies on production and costs, taxes and levies.

⁶ The wage-adjusted labor productivity ratio is an indicator of labor productivity that is derived from structural business statistics. It is defined as value added divided by personnel costs, which is subsequently adjusted by the share of employee wages in the total number of people employed, or more simply, apparent labor productivity divided by the average personnel costs (expressed as a ratio in percentage terms).

⁷ Personnel costs are the total remuneration, in cash or in kind, payable by an employer to an employee for the work done. This is divided by the number of employees (paid workers), which includes part-time workers, seasonal workers, etc, but excludes people on long-term leave.

⁸ This is an indicator of profitability that corresponds to the share of gross operating surplus in turnover. The gross operating surplus is the surplus generated by operating activities after the labor factor input has been recompensed. It can be calculated from the value added at factor cost less the personnel costs. Turnover is the total of all sales (excluding VAT) of goods and services carried out by the enterprise of a given sector during the reference period.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

The highest personnel costs were present in British, German and French coal mining. In this category, Poland comes 7th; however, the Czech Republic, Hungary, Romania, Slovakia and Bulgaria follow behind. Therefore, it may be concluded that, compared with countries with a similar level of economic development, personnel costs in the Polish coal mining industry are relatively high (higher costs were observed only in Slovenian mining).

The highest gross operating rate was achieved by coal mining in Great Britain, Slovakia and Romania. Poland is in fourth place. However, it is worth emphasising that Poland's high position in this ranking results from, periodically, very good performance of the industry achieved in the years of prosperity (2009-2010), as well as including brown coal mining in the statistics.

To sum up, the best values of economic parameters in the examined period were achieved by the British, Czech and Slovak hard coal mining industry.

Effectiveness of Polish hard coal mines in the light of the current EU legislations concerning state aid

As was mentioned at the beginning of this document, since 2010 state aid may be granted to the mining industry mostly for the liquidation of permanently ineffective hard coal mines. In order to relate the aforementioned legislations to the current situation of the two largest state-owned mining enterprises, table 7 presents the gross margin on sales in 24 hard coal mines that belong to these enterprises.

According to data included in table 7, 10 out of 24 examined mines may be considered to be permanently ineffective since, during the eight-year research period, they achieved a positive gross rate for two years at the most. That means they were able to cover production costs by sales revenues then. Two out of those 10 mines had never been profitable.

It is worth emphasising that, since 2010, profitability of all the examined mines has been systematically deteriorating. In 2012, only 7 out of 20 existing mines were performing effectively, whereas in 2009 there were 12 such units. The main reason for this crisis in the Polish hard coal mining from 2012-2013 was the uncontrolled increase of unit production costs which was not accompanied by the increase of production efficiency, either in terms of quality or quantity. The cost increase was driven by an improvement of the economy in 2009-2010 and by price increases of hard

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

coal on the global markets. A periodical improvement of financial results of the examined enterprises escalated the pay demands of trade unions, which translated into economically unjustified pay and production costs increases. Therefore, when hard coal prices decreased, the Polish hard coal mining industry was not able to comply with price and quality requirements of the leading electricity producers. Cheaper, imported coal appeared on the market (Caputa, 2008, pp. 165-177), which caused problems with sales and financial liquidity (Michalak, 2013, pp. 331-346). These days the examined mining enterprises are seriously threatened with bankruptcy .

Table 7. Gross operating rate in Polish hard coal mines from 2005-2012 [in %]

Conclusions

In the first part of the summary, there is a reference to the first research problem discussed in this article, which is formed by the following ques-

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

tion: Which countries, from 2000-2012, granted the highest amounts of state aid to the hard coal mining industry and has this found its reflection in the economic and quality results of the examined industries? From an absolute perspective, the greatest state aid was received by Germany, Spain and Poland. From a relative perspective—that is, after calculating state aid per ton of resource mined—the largest beneficiaries of state aid remained Germany and Spain, which were joined by Slovenia, with its small output but also relatively high state aid. Because of the biggest output, Poland was listed in the latter part of this ranking.

In the examined countries, the best results in terms of quality of the extracted resources were obtained by: the Czech Republic, Great Britain, Germany and Slovenia. Among these countries, only Germany and Slovenia were in the group of the three biggest beneficiaries of state aid (in relative terms).

On the other hand, taking into account the economic criteria, the best values of economic parameters in the examined period were attained by the British, Czech and Slovak hard coal mining industry. Three main beneficiaries of state aid were not present among the listed countries. Consequently, it may be stated that the intensity of state aid did not have the desired results reflected in the quality or economic effects of the three largest recipients of state aid in the hard coal mining in the European Union.

According to above it could be concluded that state interference in the economy has been largely ineffective and insufficient. The main beneficiaries have not improved their competitiveness and financial results. There are also such countries as Czech and Slovakia that in spite of much less amounts of state aid have managed to reach efficiency in free market conditions.

It is also worth noting that Polish hard coal mining is characterised by average quality and economic parameters which, in a situation of influx of cheaper and better imported coal, may become a serious threat to the existence of the entire industry. This is confirmed by the results of the effectiveness assessment of the Polish coal mines, which provides an answer to the second stated research question: What are the development perspectives of Polish hard coal mining in light of the current EU regulations concerning state aid for the industry and in the context of their current economic situation? Thus, 10 out of the 24 examined mines are mines which may be regarded as permanently unprofitable because in the eight-year research period, they only achieved a positive gross margin in two years; that is, they were able to cover the production costs by sales revenues. Two out of these

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

10 coal mines had never been profitable. It is also worth emphasising that, since 2010, the profitability of all of the examined coal mines has consistently deteriorated. In 2012, only 7 out of the 20 existing units worked efficiently, while in 2009, there were 12 such units.

Therefore, taking into account the EU ban on providing state aid to mining enterprises for initial investments, as well as limiting the scope of state aid to cover the costs of the liquidation of unprofitable mines or continuation of the started restructuring activities, it should be concluded that the examined mining enterprises will be forced to close down a dozen or so of the hard coal mines functioning in their structures. These enterprises, despite the considerable public financial support, have failed to improve their competitive position and even partially regain their permanent profitability. State aid granted to Polish hard coal mining in the analyzed period ultimately turned out to be discouraging, ineffective and inefficient.

Accounting Integration issues of EU Member States

JEL Classification: *M4; K2*

Keywords: *Legal norm; Accounting; Integration; European Union*

Abstract: The aim of this article is to discuss the dilemmas over the integration of accounting in EU member states. The dilemma could be divided into the following main groups. Dilemma of the user of financial statements. This dilemma consists in determining for whom the integration of accounting in EU is crucial, and who is the intended beneficiary of integration. Dilemma arising from the lack of theoretical framework for drafting directives and standards: the accounting paradigm assuming that accounting is strictly quantitative. Accounting is a social science, whereas the accounting practice has greater influence on social, rather than purely economic, reality. Dilemma over legal regulations and the legitimization of standard setters could be attributed to accounting regulations as legal norms. A classic example of this might be the transition from rule-based to principle-based IFRSs.

The dilemma over the legitimization of standard setters has its roots in the legal aspect of accountancy. In order to solve it, it is necessary to answer the question: 'who controls the processes of accounting integration?' since the participants of this process often present divergent viewpoints, and sometimes even opposite priorities. Dilemma over the politicization of accountancy. The more globalized and complex the economic environment is, the more of political intervention there is expected to be in the standard setting process, affected by global geopolitical trends.

Introduction

Despite the economic turmoil, economic crises, conflict in Ukraine and other European turbulences, the EU integration as we know it depicted by the EU politicians seems an idealized reality created by smart diplomatic rhetoric. This pertains also to accounting, or the dilemmas over the its integration in the EU to be more precise. The integration dilemmas could be divided into the following main groups:

- dilemma of the user of financial statements,
- dilemma arising from the lack of theoretical framework for drafting directives and standards,
- dilemma over legal regulations and the legitimization of standard setters,
- dilemma over the politicization of accountancy.

Methodology

The paper uses theories of globalization focusing on the “race-to-the-bottom” (Berle and Means,1932). Some describe the concept as the “race to efficiency,” drawing attention to the way in which global business is using financial reports and economic and political power to shift accountancy toward a more geopolitical practice. As to accountancy, basic theories are used, in particular principle-based accounting theory and normative theory of accounting.

Practical implications

The paper shows that EU corporations, accounting firms and politicians together with Europeans professional bodies are the real force able to transform accountancy in a more integrated way, relevant to EU countries.

Dilemma of the users of financial statements

There are a number of ways in which the evaluation of accountancy can help policy makers better understand the world they are bound to manage. This dilemma consists in determining for whom the integration of accounting in the EU is crucial, and who is the intended beneficiary of integration. Modern standard setters, especially those setting IFRSs, claim universal value of the solutions they develop, as well as moral neutrality, yet in fact

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

this logically contradicts the claim that investors are the main users of financial statements. Widespread international adoption of IFRS offers equity investors a variety of potential advantages. These include (International Financial Reporting Standards (IFRS): pros and cons for investors, (Ball, 2006):

- IFRS promise more accurate, comprehensive and timely financial statement information, relative to the national standards they replace for public financial reporting in most of the countries adopting them, Continental Europe included. To the extent that financial statement information is not known from other sources, this should lead to a more-informed valuation in equity markets, and hence ensure lower risk to investors.
- By eliminating many international differences in accounting standards and standardizing reporting formats, IFRS eliminate many of the adjustments analysts historically have made in order to make the financials of companies more internationally comparable. IFRS adoption could therefore reduce the cost of processing financial information to investors. The gain would be greatest for institutions that create large, standardized financial databases.
- One benefit is that reducing the cost of processing financial information most likely increases the efficiency with which the stock market translates it into prices. Most investors may be expected to benefit from an improved market efficiency.
- Reducing international differences in accounting standards to some degree facilitates removing barriers to cross-border acquisitions and divestitures, which in theory will reward investors with higher takeover premiums;

In general, IFRS offer increased comparability and hence reduced information costs and information risk to investors.

Literature is full of professional judgments on IFRS. They offer several additional yet indirect, advantages to investors. Because higher information quality should reduce both the risk to all investors resulting from share ownership and the risk to less-informed investors caused by adverse selection, in theory it should lead to a reduction in the cost of equity capital. This would increase share prices, and would make new investments by firms more attractive, other things equal. Indirect advantages to investors arise from improving the usefulness of financial statement information in contracting between firms and a variety of parties, notably lenders and managers (Watts, , Zimmerman, 1986)

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

Small investors are less likely than investment professionals to be able to anticipate financial statement information from other sources. Having regard to the treaty on the functioning of the European Union; Having regard to the proposal from the European Commission, after transmission of the draft legislative act to the national parliaments; Having regard to the opinion of the European Economic and Social Committee acting in accordance with the ordinary legislative procedure the European Parliament and of the council of 26 June 2013 introduced the Directive 2013/34/UE of on the annual financial statements, consolidated financial statements and related reports of certain types of undertakings.

This Directive should ensure that the requirements for small undertakings are to a large extent harmonized throughout the European Union. This Directive is based on the "think small first" principle. In order to avoid placing disproportionate administrative burdens on those undertakings, Member States should only be allowed to require a few disclosures by way of notes in addition to mandatory notes. In case of a single filing system, however, Member States may in certain cases require a limited number of additional disclosures where these are explicitly required by their national tax legislation and are strictly necessary for the purposes of tax collection. It should be possible for Member States to impose requirements on medium-sized and large undertakings that go beyond the minimum requirements prescribed by this Directive (directive 2013/34/EU of the European Parliament and of the Council of 26 June 2013 EC).

Many factors are linked to the financial crisis, and it is likely that poor implementation and application of fair value accounting rules has also had some effect. For example, default risk assessment was compromised, and the amount of subprime mortgage originations grew from approximately 8% of total residential mortgage originations in 2001-2003 to over 20% in each year from 2004 through early 2007 (Ryan, 2008).

Standards should be reconsidered, with less emphasis being placed on accounting rules that anticipate future income and overstate income and assets, and focusing more on appropriate implementation and standards that require bad news to be recognized when it becomes known. This timely recognition of losses would provide greater transparency to investors about the actual performance of their investments. While standards should allow for innovation and growth, accounting for company's performance must provide an accurate representation of its historical financial performance and health, with comments on fair value included only in notes or other sections of the financial statements. Other suggestions for revisions to the

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

standards include forcing banks to increase actual capital requirements in good economic times to build equity reserves to be used in the event of a subsequent downturn, and separating credit losses from other changes in fair value in the financial statements. Such objectives can be fulfilled through appropriate standards accompanied by greater enforcement, sound auditing practices, and adequate regulatory vigilance. Consideration should be given to these matters, particularly as standards will likely continue to evolve in light of future convergence with IFRS (Kothari and Lester, 2011, Kothari 2012).

The role financial reporting for fair values, asset securitizations, and derivatives played in the financial crisis is being scrutinized. The discussion is focused on banks as the center of the financial crisis. In response to the situation, the FASB and IASB have taken steps to improve disclosures relating to asset securitizations. The approach to accounting for securitizations in the IASB's Exposure Draft requiring banks to recognize whatever assets and liabilities they have after securitization is completed, better reflects the economics underlying the securitization transaction, derivatives, disclosure of more disaggregated information, disclosure of the sensitivity of derivatives' fair values to changes in market risk variables, and the implementation of a risk-equivalence approach to enable investors to better understand the leverage inherent in derivatives. Although accounting standard setters and bank regulators should find a common ground, they keep ignoring other users of financial statements and their role to reassure the society about the stability of the financial system.

In fact, today's users of financial statements are not only investors and banks. In the globalised world, with online transaction systems, economic analytical centres, virtual money, and data analysis software, which investors make their economic decisions based on audited balance sheets submitted to them six months after the reporting date? If investors bought and sold shares according to financial result, perhaps we wouldn't witness financial crises. The usefulness of financial information has been broadly questioned, due to its late presentation and complexity. The problem is that it's not useless, but rather inappropriate. The process of drafting the international standards is sometimes described as 'patch approach,' 'piece-made approach,' or 'mix attribute model' (see ISAR discussion 2010, Geneva). Hence, maybe the IFRS Interpretation Committee should add 'self-serving body' to complement their name. Now it is lawyers, prosecutors, judges, or inspectors from the Supreme Chamber of Control, the Central Anticorruption Bureau, or the Central Bureau of Investigation who make decisions

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

affecting the lives of others, based on financial statements. The target group of financial statements has changed dramatically in recent years.

”Perhaps some members of the profession would prefer to stay out of limelight. But this would risk having no voice in the development of policy. It would also open the profession to accusations that it was not playing a full role in civil society. Lawyers doctors, and other leading professions have long developed a public policy role. If accountancy accepted the wider role, there would be significant potential advantages for accountants and, indeed, for the quality of debate. (Travers, 2014)

Thus, to be overarching, the definition of the user of financial statements should read: “the user of financial statements is every person that takes binding decisions based on financial statements”. Such a definition makes the target group more universal, i.e. features the investor.(Kamela-Sowinska ,2011)

Dilemma arising from the lack of theoretical framework for drafting directives and standards

The globalization of the world of commerce has revealed the urge for international harmonization and standard setting in accounting and audit. *“If a conceptual framework is an attempt to operationalize the accounting theory, the first stumbling block is the lack of agreement on the nature and scope of this theory. So rather than having a common starting point and then a disagreement about in which direction one should go, there appear to be many different starting points, each with its own set of future avenues” (Higson, 2003,)*

The accounting paradigm assuming that accounting is strictly quantitative, i.e. in its nature based on numbers (e.g. financial result) which are then used to make economic decisions, is becoming less ubiquitous. Accounting is a social science, whereas the accounting practice has greater influence on social, rather than purely economic, reality. Thus, IFRSs should be named ‘IFRSs for financial markets’ to make a clear division between financial economy and ‘real’ economy. In principle, psychologists or experts in social and cultural studies are not engaged in setting directives, especially specific standards. This could be reflected in the composition of IASB’s bodies and other European institutions dealing with the integration of accounting, with top-notch experienced auditors, accountants, financial directors serving as former directors or heads of audit firms, banks, or rating agencies.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

IFRS Foundation does not have a research body. Its Commissions and Working Groups are composed of distinguished figures, but they are only practitioners and none of them is a lawyer, psychologist or a specialist in cultural or social studies. The tendency has been to focus on global convergence or convergence with the US GAAP, IFRS or global regulations.

The international nature of financial reporting standards is not determined by the global team of people who develop the standards, but rather by the nature and scope of the standards.(Kamela-Sowinska, 2013)

The crisis of the accounting paradigm is dying out, accounting will cease to be a standard science (compareKhun). The complexity of accounting is outpacing its precision, and once eliminated, the departures from rules reoccur in a different place. Today, an account is the first resort in any discrepancy. The external factors seem to contradict faithful representation and years of tradition. What we need is a new theory of accounting to address the present economic crisis, and determine the role of accounting in the crisis. What we used to see as a result before, now we must learn how to perceive as a cause. Financial result used to be seen as the result of undertaken actions, but today it is considered the cause of these actions. As regards the integration of accounting in the EU, I can see clear lack of theoretical premises to effect the proposed changes. Only consistent application of accounting theories in the integration process could ensure linguistic precision, clarity, argumentative order, and correlation between the specialist language and both practice and social awareness.

**Dilemma over legal regulations and the legitimization
of standard setters**

Another dilemma over the integration of accounting could, in my view, be attributed to accounting regulations as legal norms. A classic example of this might be the transition from rule-based to principle-based IFRSs. In literature, it is common for accounting rules to be juxtaposed with accounting principles. However, it is unjust to distinguish between the two. Principles and rules (or legal principles and norms according to the Polish science of law) differ as to the mode they function. Rules (norms) are based on the 'all or nothing' concept, i.e. they are or aren't met. On the other hand, standards (principles) may be observed to a certain extent. Compared to rules, in case of two conflicting standards, principles do not overrule one of them, but are used to give priority to one over the other, with both remaining in force. The application of norms is precisely determined, which is not

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

the case for principles. In addition, rules are applied automatically in particular situation, e.g. double entry rule, whereas the use of principles is conditional upon the entity's assessment of a situation, e.g. the choice of asset measurement method.

One could refer to Dworkin fundamental work *Taking Right Seriously*, and the famous polemics of John Mackie. Dworkin splits the law into rules and standards, with the latter covering *principles* and *policies*. *Principles* are legal norms to be observed, because they constitute requirements attributed to a certain moral system (justice or honesty). *Policies* mean standards determining general objectives of social, political, and economic activities. Both types of standards require certain state of affairs to be satisfied to the highest possible extent, with legal and actual functions determining the feasibility of this process. In 2006 critical analysis of confusing rules with principles in drafting accounting standards and standards on auditing was carried out by Benston, Bromwich, and Wagenhofer (2006). However, I couldn't find any reflection of or discussion over, the global heritage of the theory of law or accounting.

The growing acceptance by countries across the globe of International Financial Reporting Standards (IFRS), issued by the International Accounting Standards Board (IASB), is being used by some to suggest that the IASB is a model for a transnational standard-setting body (compere Lloyd et al, 2007; Büthe and Mattli, 2008).

The increasing use of transnational standard-setting bodies to address quality uncertainties and coordination issues in the global economy raises questions about how these bodies establish and maintain their legitimacy and accountability beyond the sovereignty of democratic states. Discussion about legitimacy has increasingly emphasized due process norms in its claim for support. The analysis evaluates the IASB due process against the cultural benchmarks established by domestic standard-setters in the USA and UK and against a normative model of procedural legitimacy. These comparisons help to understand the modifications that were made in the hope due process would add legitimacy to setting accounting standards beyond the state level. They also reflect the broader political context of competing legitimacy criteria faced by transnational standard-setters. (Richardson, Eberlein, 2010)

The European Parliament (EP) of the European Union, which accepted the IFRS as the basis for financial reporting by companies starting to operate in 2005, noted in the 2008 motion, adopted by its Committee on Economic and Monetary Affairs, that the IASB: "... is a private self-regulatory

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

body which has been given the role of lawmaker for the EU... [the EP] underlines that the IASCF/IASB... lack transparency, legitimacy, accountability and are not under control of any democratically elected parliament or government, without the EU institutions having established the accompanying procedures and practices of consultation and democratic decision-making that are usual in its own legislative procedures..." (European Parliament, 2008, p. 4).

This dilemma has its roots in the legal aspect of accounting. Broadly speaking, legitimization means justification or legality of a certain social formation. Most common concepts are: legitimization of power, state, or law.

Legitimization of law means justification of law and perceiving it as fair. Legitimization of law is often intertwined with legitimization of power. Interchangeably with legitimization, such concepts as *justification*, *empowerment* or *rationale behind the binding force* are used. Usually, legitimization is analyzed from normative or empirical perspectives. In normative terms, the concept refers to the justification of certain legal norms. All legal norms, as well as the legal system in its entirety, should have such justification (reference to a certain system or quality) to deserve respect and be regarded as law.

Empirically, legitimization means actual compliance with the law. Therefore, high legitimization of laws demonstrates itself in its provisions being followed by a given society.

Legitimization could be viewed from more or less general perspectives. Thus, we can talk about legitimization of specific legal norms or decisions to set and apply laws, or about legitimization of the entire legal system. The integration of accounting laws should be seen from the second perspective.

The IASB does not have the status of an international body such as IFAC, the World Bank, IMF, or the EU. For the proposed standards to obtain legal force, they must be subject to so called *due process*. The significance of *due process* has been referred to on IFRS Foundation's website by David Sidwell, Trustee: "we will look at providing more robust documentation to demonstrate the oversight."

IASB is an institution established in accordance with legal criteria for developing international accounting and audit regulations, hence its activity is rather legal than legitimized.

Without legitimization it wouldn't be possible to exercise power, or establish proper relationships between the authorities and the society. Thus, it is necessary to determine general principles for legitimization, adequate for

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

a given model of governance. In fact, such legitimization remains in the hands of a national legislator.

The discussion over the legitimization of the accounting law requires answering the question: “who controls the processes of accounting integration?” since the participants of this process often present divergent viewpoints, and sometimes even opposite priorities. If we look at IFRS for SMEs, they are not commonly accepted by the accounting profession in the EU, and are still subject to standardization.

Reporting standards for public finance sector should be of particular interest within the EU. The present crisis in Greece, and the imminent crisis in the Southern Europe require focusing on this area of accounting. So what? Well...nothing.

Dilemma over the politicization of accountancy

Over years there was no law on accounting, neither an act nor a code of accounting. There was only practice, which determined how to recognize the results of economic decisions and present them in the measure of value – money. The first modern code containing accounting standards was the Napoleon’s Code of 1807 and Commercial Code of 1808 (Code de Commerce); followed by German commercial law BGH Burgerliche Gesetz Buch of 1900. The regulations of the Commercial Code and the Napoleon’s Code referred to keeping and using accounting books and preparing a bankruptcy balance sheet. Title II of the Napoleon’s Code dealt with merchandise books. For example, in article 10 it obligated merchants to sign the register book and inventory book every year [Turzynski 2010].

Today we have accounting law, IASs, IFRSs, GAAP, IPSASs. There is a huge number of organizations that formulate rules, principles, conceptual frameworks, accounting standards. The most important of them are: IASB, IFRSB, IFAC, EFRAG, IFRIC, SAC. Most of the international organizations mentioned above all act in the public interest, hence allegedly in the interest of all citizens in the world. Nowadays politicians create accountancy, as they have the power to create the law. This is what is called a politicization of accountancy. The number of publications has risen (Ball., 1995; Colasse, 2004; Graham. and Neu, 2003; Nobes and Parker, 2012).

Literature indicates that the phenomenon is linked to the emergence of critical accounting research, which assumes that accountancy is not a neutral and objective tool aiming at improving the effectiveness of financial markets, but on the contrary – a practice that allows to transfer wealth

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

among social classes. Hence, accountancy influences the authorities in the area of political economics, but at the same time it is influenced by them, as it functions within certain political frameworks. Accountancy has therefore a political function – the accounting principles are shaped by the group in power and their ideology and, on the other hand, accountancy influences the way in which profits, wealth and power are being distributed within the society. Literature on political accountancy encompasses works which investigate how accountancy can be engaged in social conflicts and in the process of profit distribution not only within one company, but within the capitalist society as a whole. The research also includes a study on the role of accountancy in the interactions between a country's economic policy and free-market economy [Dobija, 2010].

A Corporate Social Responsibility report, (CSR report) is supposed to present what a particular company decided to do in the following three areas: economic, social and environmental, and whether it has managed to accomplish the goals set. A report on sustainable development is an important source of information for financial analysts who formulate prognoses regarding future financial results of the company. Based on the information included in such reports, their prognoses are more precise and reliable. By preparing a CSR report, the company contributes to building better social and environmental conditions, and consequently - it may trigger positive changes in the global economy. Moreover, emphasizing its openness and transparency, the company improves its relations with local community, non-profit organizations etc.

A CSR report can also play a role of a marketing tool, which creates an image of a company devoted to social and environmental issues. It can help the company to gain advantage over its competitors, who are less concerned with the idea of sustainable development. By promoting activities in the area of sustainable development, companies promote transparency and responsibility over their actions and results.

The more globalized and complex the economic environment is, the more of political intervention there is expected to occur in the standard setting process. Regardless of whether the standard-setting institutions represent the public or private sectors, accounting principles will be shaped by the global geopolitical reality, so by following this tendency, accountancy is obtaining geopolitical knowledge and practice in EU countries.

Conclusions

The developments of international accounting bodies and standard setters have played a vital role in ensuring best accounting and audit practices will be disseminated across the complex modern world. On the other hand, it heralds a number of problems that will have to be solved in near future.

The main role of implementing new solutions in accountancy and audit may be played by IFAC which, in a document “Enhancing organizational reporting” stated that IFAC:

- Supports organizational reporting of broad-based information that is important to stakeholders for managing and directing operations, decision making, promoting transparency, and the discharge of accountability;
- Supports such reporting in accordance with robust international reporting frameworks that produce information on which assurance conclusions can be expressed, in accordance with high-quality international assurance standards;
- Recognizes that the accountancy profession has a significant contribution to make, and an important role to play, in developing and implementing enhanced organizational reporting.
- Professional accountants also play an important role in broad-based organizational reporting arrangements, and in providing assurance;
- Strongly supports the International Integrated Reporting Council (IIRC) and the development of the Integrated Reporting (<IR>) Framework; and
- Recognizes that there is a range of different frameworks and regulations available and being developed, and considers it important to examine the relationship between these frameworks and to promote global consistency and convergence” (www.IFAC.org, IFAC Policy Position 8, October 2013).

Key focus areas of discussion related to the integration of accounting in the EU are as follows:

- whether to strengthen the role of the World Bank, IMF, EU, and IFAC in developing accounting standards for the public finance sector and focus the standardization of business accounting exclusively on listed entities; / is it reasonable to strengthen
- whether to strengthen the role of Directives and Conceptual Frameworks as the basis for regular accounting to clearly define practical rules and principles; / is it reasonable to strengthen

**Healthcare in the Light of the Concept
of Welfare State Regimes – Comparative
Analysis of EU MS**

JEL Classification: *A11; H51; I18; P16*

Keywords: *welfare state; health care; decommodification*

Abstract: This paper addresses issues related to health care in the context of the debate about the typology of welfare state regimes and comparative studies conducted by reference to the debate. Particular attention has been paid to the phenomenon of decommodification as one of the key dimensions that define welfare regimes identified in the literature associated with this debate. The study presents a health decommodification index, on the basis of which an attempt has been made to assess the decommodification potential of health care, taking into account the situation in the 28 EU Member States in 2012. The identification of broadly understood accessibility of publicly funded health care as a basic measure for assessing the decommodification features of health programs is an important result of the empirical analysis. The study has also confirmed the views expressed in the literature about the existence of practical obstacles standing in the way of developing a universal typology of welfare states.

Introduction

Although it is difficult to provide a clear and comprehensive definition of the welfare state, the specific characteristics underlying the concept of welfare state are commonly acknowledged. One of the main features of this

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

concept indicated in a textbook definition is that it involves state responsibility for securing some basic, modest standard of living for its citizens. Other presentations concretise this definition by reference to certain areas of state activity and relevant criteria of social justice (Barr, 1992). In contemporary welfare states, especially European ones, attention is drawn to the key role that the state plays in matters relating to social security, health care, education, housing and working conditions as well as to the principles of equal opportunities and fair distribution of wealth.

The issue of the functioning welfare states and their typology has for many years been at the heart of research and interest in many scientific disciplines, and of social policy decision makers. Theoretical concepts are confronted with the effects of policies and programs pursued within the framework of social security systems. As the E. Karpowicz (2006, p.4) states "social policy is primarily a practical activity but that practice has always been accompanied by investigations aimed at resolving the basic concept, at focusing efforts expressing different views and opinions which ultimately determine the practical arrangements". Szarfenberg R. (2009, p.17) emphasizes the importance of social policy models as a tool to simplify its potential complexity what would allow its characterization and comparison in different times and places.

Comparative analysis of social security systems is accompanied by an interest not only in the extent to which welfare states differ from each other and to what extent they are similar to each other but also in how these similarities and differences may explain the effects of implemented social policies. Particularly noteworthy is the Esping-Andersen' (1990) concept of *the three worlds of welfare capitalism*, in which one of the basic criteria for differentiating the welfare state regimes was the extend of decommodification of the status of individuals in relation to the market. For its assessment the author has examined the decommodifying features of social security programs in the 18 OECD countries using selected indicators related to various types of cash benefits under their income maintenance programs. The extent to which the author's criterion of differentiation and assignment of states to individual welfare state regimes works in the health care sector and, consequently, whether the concept of the three worlds is universal constituted and still does constitute the subject of research investigations (Kasza, 2002, Bambra, 2005a, 2005b, Yu, 2012).

This paper furthers this research trend and aims to assess the decommodification potential of the health care systems in the 28 EU Member States based on 2012 data. In order to accomplish this aim two health care

decommodification indexes have been constructed using different set of measures. This has allowed to examine the concept of health care decommodification and to enrich inference.

The paper's structure and layout have been subordinated to this very goal. First, the author makes a review of literature on typology of welfare state models, with particular emphasis on Esping-Andersen's concept of 'three worlds of welfare state capitalism'. Then, relying on the research method the author presents the results of empirical study and discusses them in the context of a widely understood accessibility of publicly funded health care. Finally, the author draws conclusions, including those as to the usefulness of G. Esping-Andersen's typology of welfare state regimes in relation to the health care sector.

Review of the literature

Relying on reviews of pertinent literature one can indicate two models of the welfare state identified by H. L. Wilensky and C. N. Lebeaux, (1968) i.e. the *residual (marginal)* model in which the intervention of social institutions is justified on the grounds of market or family failure, and the *institutional (redistributive)* model in which social support is treated as a universally acceptable first line function of the state (Van Kersbergen, 2012, p.140, Schustereder, 2010, p.18). R. Titmuss (1974) extends this typology by adding to it the so-called *an industrial-achievement-performance* model in which both the entitlement and the scope of social benefits granted to its beneficiaries is dependent upon their merits, performance and efficiency (Van Kersbergen, 2012, p.140, Schustereder, 2010, p.18). Incidentally, N. Furniss and T. Tilton (1977) also distinguished three models of the welfare state and described them as the *positive state* in which social policy is intended to protect the owner of the capital from the difficulties associated with the interplay of market forces and from the demands of revenue redistribution, the *social security state* in which the goal of social policy is to guarantee a minimum income for all citizens and the *social welfare state* in which the goal of social policy is to equalize the conditions of life of all citizens (Karpowicz, 2006, p. 4).

What is particularly noteworthy is G. Esping-Andersen's (1990, 1999) concept of the three worlds of welfare state in which the author distinguishes three types of welfare regimes: liberal, conservative and social democratic. The basic analytical axis in the above typology was, like in most accepted classifications, a juxtaposition of private and public spheres,

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

while in contrast to previous studies¹, the key dimensions that define the separate regimes are: i) the degree of decommodification referring to the level of individuals' self-sufficiency from the labour market which arises from the existence of cash benefits systems, and ii) stratification or group solidarity models described by the author (G. Esping-Andersen, 2010b, p. 96). The operationalization of adopted dimensions resulted in the assignment of 18 OECD countries to one of the three regimes.

The *liberal* regime is based on market mechanisms. The author assigned to it those states which are characterised by a modest, mean tested, universal systems of social transfers or modest social security systems. This approach to social benefits is an expression of minimal state intervention, individualisation of risk and promotion of market-based solutions. The author indicates that this type of welfare state results in minimisation of the scope of decommodification, limitation of the area of social entitlements and the establishment of a system of social stratification, which is a blend of 'equality in poverty' and 'market-differentiated welfare of the majority' (G. Esping-Andersen, 2010a, pp. 44-45)².

The *conservative* regime, grounded both in the market and in the family, was revealed in countries whose programs and social benefits are universal, their scope generally differentiated on the grounds of professional status and income, and their administration essentially the responsibility of employers. Government intervention in the market is justified by a failure of the family, which determines its subsidiary character. G. Esping-Andersen indicates that the regime results in a moderate level of decommodification, the primacy of the social assistance over entitlements and favouring the consolidation of the existing social divisions as a result of social policy³.

On the other hand, the *social democratic* regime in which the state assumes primary responsibility for the welfare of its citizens is typical of countries where social programs are universal and egalitarian, and benefits granted are of a relatively high level, often close to the amount of the average income. The state actively supports jobs and income protection, which, in turn, translates into a wide range and high level of decommodification. G. Esping-Andersen points out that state involvement and the minimisation of the function of the market leads to the emergence of conditions condu-

¹ Most researchers focused on the volume of welfare spending and its share of GDP.

² In the study group the features of the liberal regime were ascertained in Australia, Canada, Ireland, New Zealand, Great Britain and the USA.

³ In the study group the features of the liberal regime were ascertained in Austria, Belgium, France, Germany, Switzerland, Italy, Japan and the Netherlands.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

cive to a reduction in social divisions and strengthening of social solidarity⁴.

G. Esping-Andersen's concept of the three worlds was for many researchers a reference point for further studies and comparative analyses and the voicing of more or less critical remarks. Some verified the welfare "order" in the 18 OECD countries covered by G. Esping-Andersen (Leibfried, 1992, Castles & Mitchel, 1993, Bonoli, 1997, Korpi & Palme, 1998)⁵, others tested this concept in other countries (Ferrera, 1996, Ferreira & Figueiredo, 2005, Gough, 2006, Walker & Wong, 2005)⁶ or with reference to other social policy areas such as health care and education (Bambra, 2005a, 2005b, Yu, 2012, Czarnecki, 2014), analysing larger sets of countries and more recent data. As a result, objections were raised as to the usefulness of the concept of the three worlds for comparative research (Baldwin, 1996, Kasza, 2002), its theoretical and methodological shortcomings (Lewis, 1992, Gough, 2001, Arts & Gelissen, 2002, Powell & Barrientos, 2011).

Methodology of the research

The author's research methodology involves the use of the health de-commodification index as one of the possible methods of assessing the level of decommodification characteristics of the health care system. To construct such an index G. Esping-Andersen's method has been adopted (2010a, pp. 77-78). As a starting point the health decomodification index proposed by C. Bambra (2005a) was examined. Then, by analysing the results obtained within this index (index I), the author proposed two new indicators and constructed the second index (Index II).

The first index (Index I) has been constructed through the assessment of three measures (Bambra, 2005, p.34):

- private health expenditure as a percentage of GDP,
- private hospital beds as a percentage of total bed stock,

⁴ In the study group the features of the social democratic regime were revealed Denmark, Finland, Norway and Sweden.

⁵ The research resulted, among others, in proposals advocating the assignment of certain countries (e.g. Austria, New Zealand, Japan or Italy) to another regime.

⁶ The research resulted, amongst others, in a suggestion whereby additional regimes should be isolated, e.g. for Southern European countries, Central and Eastern Europe or even certain Asian countries.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

- the percentage of population covered by the health care financed by public means.

The second index (Index II) has been constructed through the assessment of following measures:

- 1) household out-of pocket payment as a percentage of total current health expenditure,
- 2) the percentage of population reporting difficulties in having their basic medical needs met,
- 3) the percentage of population covered by the health care financed by public means.

The degree of decommodifying features of the health care system has been determined by adding the results (points) awarded for the place on the scale (in the ranking of countries) for the above indicators. On the basis of the position of each of the 28 EU countries on the respective scales, between one and three points have been awarded, denoting a low, medium or high level of decommodification, respectively. The point award has been based on the difference between the mean value and standard deviation, in several countries adjusted for extreme values. Sub-index values were then weighted by means of the index of the share of the population entitled to benefit from public services.

The underlying statistics used to compile these indexes have been sourced out from EUROSTAT, OECD and WHO databases, with 2012 data used as the reference year. Whenever 2012 data were not available use has been made of data from the few years adjacent to the reference year, and in the absence of any data use has been made of the EU average with adjustment when necessary for extreme outliers. Table 1 and table 2 below present data (indicators) and author's own calculations used in the paper.

Results

Analysis of the results shows that the adoption of different measures for the assessment of decommodifying features of health care systems has a significant impact on the final results, both in terms of the indexes values attributed to each of 28 EU MS and consequently of their position on the indexes scale.

In the case of the first index (index I) the potential spreads out between 17 points (Cyprus) and 60 points (United Kingdom), the average value of the index for all EU countries being 38 points. The research method adopted has yielded a distinction into three groups of countries, revealing low, medium or high level of decommodifying potential, respectively. The group of low decommodification index countries (index value ranging from 17 to 24 pts) consists of four countries – two so-called the new Member States⁷, i.e. the already mentioned Cyprus, and Bulgaria, as well as Portugal and Greece. By contrast, the group of high decommodification index countries (index value between 50 and 60 pts) consists of six countries, including five new Member States (Romania, Czech Republic, Lithuania, Slovenia, Croatia) and the UK. The remaining 18 countries, including six new Member States, belong to a group of medium decommodification index level countries, with the index ranging between 27 and 49 points.

The results presented in the framework of this index give rise to doubts especially when one compares the index scores of such countries like Netherlands (30 pts) and Greece (24 pts), Germany (27 pts) and Bulgaria (23 pts), or Luxembourg (49 pts) and Romania (50 pts). Although, the index scores in compared countries are very close to each other in reality these countries differ in many aspects of health care provision. As an example one can point to significant differences in the level of general government health expenditure per inhabitant in Euro/PPS in these countries: in Netherlands (3250) compare to Greece (1217), in Germany (2725) compare to Bulgaria (500), or in Luxembourg (3348) compare to Romania (587)⁸.

⁷ Countries which joined the EU in 2004 (Cyprus, Czech Republic, Estonia, Latvia, Lithuania, Malta, Poland, Slovenia, Slovakia, Hungary) and later in 2007 (Bulgaria and Romania) and in 2013 (Croatia).

18-19 June 2015, Economics and Finance**

In the case of the second index (index II), both the span of the decommodifying potential of health care systems in the countries studied (values ranging from 15 and 60 pts) and its average value for the EU 28 (37 pts) have not changed significantly. On the other hand, the index of 16 Member States has changed, which, in turn, has led to a shift in the position of the Member States on the index scale and, consequently, the current assignment of some of them to the three decommodification level groups distinguished (Table 3). For example in the case of Croatia, but also Romania and Latvia, the score of the second index compared to that of the first index has decreased by 30 and by 20 points (for the last two countries) respectively, while in the case of Holland, but also Austria, France and Portugal, it has increased by 30 and by 20 points (for the last three countries), respectively. Thus, the group of low level decommodification countries (index values ranging from 15 to 25 pts) now features Cyprus, Bulgaria, Greece and Latvia and the group of high level decommodification countries (index values between 49 and 60 pts) includes Slovenia, the United Kingdom, Luxembourg, Austria, France and the Netherlands. The remaining 18 countries are classified as medium level decommodification countries, with the index ranging between 27 and 49 points.

Discussion

The use of two health decommodification indexes in the study has enriched inference. The first one which has been taken as a starting point for analysis was developed by C. Bambra who, for the purpose of her study, extended G. Esping-Andersen's concept of decommodification for the health care sector, which she defined as 'the extent to which an individual's access to health care is dependent upon their market position and the extent to which a country's provision of health is independent from the market' (2005a, p. 33). In order to enhance comparability between the health care and the labour market decommodification indexes C. Bambra has examined the same 18 OECD countries and made reference to the same period of study (1980) as G. Esping-Andersen did. She has chosen three indicators⁹ to operationalize the basic analytical axis consisting in a juxtaposition of the private and public health care sectors. To illustrate this relationship she has considered, in turn, three aspects of the functioning of health care systems, namely: financing, provision and accessibility of health care services.

⁹ The availability of statistical data in reference to the time period of C Bambra's study might had been a decisive factor for the choice of these indicators.

Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

During the evaluation of this approach in the context of the definition of decommodification of health care as suggested by the author, it has been noted that the three indicators proposed by C. Bambra do not allow to capture a complete and real picture of the extent of market dependence / independence in both areas.

The first indicator e.g. private health expenditure as a percentage of GDP refers to 'the extent of private enhancing by identifying the extent of a country's total income that is spent on private health care' (Bambra, 2005a, p.34). Thus in the nominator next to household out-of pocket payment, are included expenditure of private insurance, of non-profit organizations serving households and of corporations (other than health insurance). It is worth also to be aware that the adoption of the GDP as a denominator may lead to misinterpretation of the level of the indicator due to the differences as to the direction and the rate of changes of GDP and of healthcare spending. Such can occur especially in times of economic change.

The second indicator, in turn, i.e. private hospital beds as a percentage of total bed stock relates to only one mode of health care provision i.e. inpatient services provided by hospitals and thus reflects the ownership of the private means of production to a limited extent. Moreover, in contemporary health care systems the public payer contracts the services from both public and private providers of health care.

The third indicator, i.e. the percentage of the population covered by publicly funded health care, is an important measure of the extent of general access to these goods and services, nonetheless cannot be treated as a perfect measure of public health services accessibility due to the fact that in all health care systems individuals are required to contribute to their cost at the point of use.

In order to address above mentioned shortcomings, the author has proposed two new indicators, which, analysed in conjunction with Bambra's third indicator has led to the construction of the second index. It has allowed to focus analysis on issues related to a widely understood accessibility of publicly funded health care goods and services, that in the view of the author is considered to be a key to the assessment of the decommodifying potential of health care system. The reasoning behind the author's approach is briefly discussed below.

For the purpose of this study the health care decommodification refers to the extent to which an individual's access to health care is not dependent on their market position. Such approach follows the first part of C. Bambra definition *à rebours*. This approach is also in line with G. Esping-Andersen

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

notion of de commodification, which ‘occurs when a service is rendered as a matter of right, and when a person can maintain a livelihood without reliance on the market’ (1990, pp.21-22). Such a broad conception of de commodification has been also adopted by other researchers, including O. Pintelon (2012, p.8) who defined it ‘as any state intervention removing individuals from total dependence on market forces’ and J. Vail (2010, p. 313) according to whom de commodification refers to ‘any political, social, or cultural process that reduces the scope and influence of the market in everyday life’.

The specificity of the health care sector stems both from the common perception of health as a value *per se* and as a precondition for economic prosperity. From an individual’s point of view good health is valued because it allows to provide happy and productive lives. From a society’s point of view protection of citizens’ health is valued because it has an impact on ‘economic outcomes in terms of productivity, labour supply, human capital and public spending’ (EC, 2013, p. 1). For that reasons, health care on European ground is regarded as one of the pillars of the European contemporary welfare states, and the functioning of national health systems is one of a key element of EU’s broader ‘social infrastructure’. It includes both a system of overarching values the most important of which are: the universality of health services, accessibility of high quality health care, equity and solidarity, and a common to European health systems set of rules of conduct governing quality requirements, safety of provision of health care services based on scientific evidence and ethical principles, patient involvement, redress, privacy and confidentiality (EC, 2006).

Analyzing the above values and principles at the level of their practical implementation, one should emphasise that health systems vary across the EU MS. The underlying reason for their variety has been, and continues to be, the choices of systemic solutions made as part of the underlying historical and cultural development as well as of economic and political conditions, including those relating to the rules governing the award of entitlement to public health services or their funding mechanisms and the organization of these benefits.

Firstly, the entitlement to public health services in EU MS can be either recognized as a universal entitlement of all citizens or a subjective right arising from an insurance contract. Thus the public means for health care can be generated either via a tax system or a social health insurance or by a combination of both. As pointed out in Table 1, the public coverage of health care costs for a core set of services is either universal or close to it in

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

all EU Member States. The exception is for example Cyprus, where the public health system, although financed through general taxation, does not secure universal coverage except for these with a low income level. As a consequence, approximately 17% of Cypriots, mainly those of high annual income as well as EU citizens who are not eligible for public health care in their home countries and all legal and illegal immigrants from non-EU countries living in Cyprus, must pay out of pocket to access the public health system, or purchase health care from the private sector (HIT, 2012, p 35). In Greece (79%), two main rules of entitlement co-exist: one on the basis of citizenship for outpatient services provided by the national health system (ESY) and second on the basis of occupational status and insurance contributions for different type of services either provided or financed by insurance funds, ESY or private providers (Economou, 2010, p 18). Both in Cyprus and Greece, have been taken health reform, including these relating to the extension or consolidation the coverage by the public health care, due to the need to implement the recommendations of the adjustment program (Kawiorska, 2014). The relatively low level of public coverage indicator is also observed in Germany (89%). In this country the possibility for opting out of the Statutory Health Insurance (SHI) system and switching to Private Health Insurance (PHI) is seen by certain groups of people as a pragmatic way to save money or, in the case of self-employed individuals, as a necessity since many of them are not eligible for SHI coverage (Busse R., Blümel M., 2014, p 53.). The low level of public coverage indicator can also be observed in Member States where social health insurance is closely related to the labour market. In these countries the share of uninsured population increases with economic downturn, being a reflection of decreases in the labour market participation. Examples are Bulgaria (77%), Greece (79%), Estonia (93%) or Poland (97%)¹⁰.

Secondly, as mentioned earlier public coverage for health care is not a perfect indicator because the range of medical goods and services publicly covered as well as the type and level of cost-sharing that applies to those goods and services vary considerably across European countries (OECD, 2014, p. 108). This variation applies both to form (direct payment, cost-

¹⁰ The ongoing financial crisis of 2007 meant that in most EU countries people out of work for a longer period of time lost their entitlement to unemployment benefits and, consequently, their entitlement to free health services, and equally affected self-employed people who were not able to pay health insurance premiums due to a drop in their income. The crisis also manifested itself in an increase in the number of people employed under contracts that did not guarantee employer's contributions to the system.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

sharing, informal payments) and level of household out-of-pocket payments for health care. Hence the other indicator, i.e. the share of household out-of-pocket expenditure¹¹ in total current health care expenditure has been taken into account for the purpose of this analysis. This indicator captures the financial burden on household budgets. Analysis of this ratio (Table 2) indicates a very large diversity of its size across the EU Member States in 2012. The least financially burdened were households in the Netherlands, France and the UK, where the size of the household expenditure did not exceed 10% of total current health expenditure, while the most burden was borne by households in Cyprus, Bulgaria and Latvia, in which the share was several times higher and represented an equivalent of 47%, 43% and 34%, respectively.

Thirdly, in the context of assessment of the decommodifying potential of healthcare programmes, the situation of the patient, who is the primary recipient and the potential beneficiary of health services should be an important aspect of the analysis. It has been done by the incorporation into the analysis of the third indicator that refers to the percentage of the population reporting difficulties in having their basic medical needs met. This indicator makes it possible to take into account patients' subjective opinion on what they feel are barriers to medical services accessibility. In 2012, in the EU-28, just 3.4 % of the population reported unmet need for medical examination or treatment of which 67% were reported due to a lack of funds, 29.4 % due to a long waiting lists and 5.9% due to the distance to the place where medical services are provided, or the lack of means of transport¹². Just as in the case of the analysis of the previous indicator, also in the case of the indicator in question, one can tell big differences in the situation of the citizens of the EU Member States. The highest percentage of the population reporting difficulties in access to medical services, ranging between 8 and 12% was ascertained in Latvia, Romania, Poland, Estonia, Bulgaria and Greece, while the lowest, not exceeding 1% of the total population, in Slovenia, Austria, the Netherlands, Luxembourg and Spain (Table 2). In

¹¹ Household out of pocket expenditure can comprise both the direct payment for purchasing health care goods and services in the private market and the required contribution to the costs of publicly financed goods and services at the point of use. In some countries it also comprises unofficial payments that may allow patients, for example, to avoid a long waiting list or to receive more care or of a higher-quality.

¹² EU statistics on income and living conditions (EU-SILC): Self-reported unmet needs for medical examination, by sex, age and reason (%) [hlth_silc_03], Eurostat database (07.01.15)

**Proceedings of the 8th International Conference on Applied Economics

18-19 June 2015, Economics and Finance**

countries with the highest proportion of the population reporting difficulties in access to the benefits, lack of funds or too expensive treatment were indicated as their main reasons (Romania - 90%, Latvia - 85%, Greece - 81%, and Bulgaria - 72%), together with long waiting lists (Estonia - 77% and Poland - 56%).

Discussed above three measures underlying the construction of the second index has enabled to assess the decommodifying potential of health care provision taking into account a widely understood access to health care benefits financed from public funds in the Member States.

The indicator that refers to the public coverage of health care costs for a core set of goods and services illustrates the extent of general access to these goods and services that depends on the rules governing the award of entitlement to public health services. In other words it illustrates the extent to which the adoption of certain rules of governing can protect citizens against the economic fluctuations.

The indicator that refers to the ratio of household out-of-pocket expenditure on health care to the total current health care expenditures reveals a real level of financial burden of households that arises due to the various funding mechanisms of health benefits adopted by the country. This indicator is commonly considered as one of the measures of health services accessibility in practice.

The last indicator that refers to the self-reported unmet need for medical examination or treatment shows the scale of encountered barriers to access of those seeking health care. Both the scale and the reasons of these barriers can indirectly reveal the outcome of the countries' systemic solutions, including those related to financial and some of organisational aspects of health care provision.

The concept of the three worlds and further comparative research conducted by reference to it together with the findings of this study allow to formulate two main conclusions. Firstly, in terms of values and principles the health care programs in EU MS that aim to protect against the risk of loss of health differ from social security programs that aim to protect against the risk of loss of income. The former based on the principle of universal citizenship and equality, exhibit characteristics typical of high decommodification level regimes, whereas the income security programs implemented in those countries, if based on the principle of individual risk and professional performance, will exhibit characteristics typical of medium or low decommodification level regimes.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

Secondly, analyzing the above values and principles at the level of their practical implementation the extent of a widely understood accessibility of publicly funded health care good and services varies across the EU MS. These results show that even convergence of the values and principles between health programs and income security programs in such countries like Denmark, Finland, or Sweden wouldn't necessarily lead to reveal of similarities in decommodifying potentials of both types of programs.

It should be also pointed out that presented assignment to a different decommodification level groups of countries has been partially determined by the methodology applied. The use of the mean value and standard deviation as the criteria for determining the intervals for fitting countries into different groups has led to the assignment of certain countries to the same group despite a large distance between the values of the indicators and vice versa, in the inclusion of countries into different groups, despite a small distance between the values of these indicators for these countries. This confirmed some criticism about the drawbacks of the adopted methodology (Bambra, 2005a, Castles & Mitchel, 1993, Powell & Barrientos, 2011).

The results of the study also confirm criticism voiced in existing literature as to the usefulness of the concept of the three worlds for comparative studies. Thus, the present study fits into a trend of empirical studies that reinforce the view presented, among others, by researchers such as G. J. Kasza (2002), pointing to the existence of practical obstacles to the development of a universal typology of welfare states due to a lack of internal coherence of national social security schemes. This lack of coherence is due to the specific nature of the various fields in which social programs (e.g. education, health care and social security) are implemented, as well as to variations in the shaping of policies within each of these fields, a diversity of players, and the dynamics of change within individual social policy areas, including the effects of convergence with respect both to the practical and normative solutions used in different countries (Kasza, p. 282). In the light of the study dedicated to EU MS, the argument referring to the effects of convergence has a significant meaning due to the various initiatives undertaken by the EU institutions aiming to promote and coordinate health policies in the Member States.

Conclusions

The importance of G. Esping-Andersen's concept of the three worlds can be gauged from the stand point of the intensity of the ongoing scientific

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

debate about the proposed typology of welfare state regimes, as well as from in terms of the fact that the debate continues to this very day. The issues discussed in this paper are part of the mainstream of the debate, and they focus on the assessment of the decommodifying potential of health systems in the light of the concept of welfare state regimes. This study has confirmed that health care is essential in contemporary European welfare states and that state involvement is equally essential for the functioning of health care systems in the EU. The extent to which the state involvement in health care area secures the individuals' access to health care regardless of their market position should be indicated as a basic measure for assessing the decommodifying potential of health care benefits. The analysis proves it that convergence of the values and principles underpinning the health care systems of the EU Member States does not in itself determine that the result of their practical implementation will be an identical or a similar scope of a widely understood access to health care benefits financed from public funds in the Member States.

The extension of a set of indicators that would allow the continuation of studies, for example, of the assessment of existing social inequalities in accessibility of health services or a sense of security or satisfaction of patients using public health care is an open issue. Such studies undoubtedly will contribute to a more definitive conclusion as to the real decommodifying potential of health care systems in the UE MS.

Macroeconomic Policy Regime in Poland*

JEL classification: *E02; E58; E61; F41; F43*

Keywords: *Macroeconomic regime; open economy policies; emerging countries; industrial policy; Poland*

Abstract: The goal of this paper is to analyse the economic development of Poland using the concept of macroeconomic policy regimes (MPRs). Six elements of a MPR will be identified: foreign economic policy, industrial policy, the financial system, wage policy, monetary policy and fiscal policy. Examining the functionality of the development of these elements applied to Poland is a further aim of this paper. The functionality of the development of the MPR elements will be analysed on the basis of the fulfilment of the objectives, as well as the use of the proposed instruments and strategy assigned to every element of MPR. Due to space limits, we are going to focus on the former in this paper.

Taking into consideration that Poland is an emerging and a relatively open economy, foreign economic policy and industrial policy play very significant roles in restructuring of the economy towards production and exports of high value-added products, which would enable the country to follow a growth path consistent with an external balance. The financial needs of the manufacturing sector and particularly of the producers and/or exporters of high-end products need to be satisfied by the financial system, whose stability needs to be secured with the help of monetary policy. The latter is, moreover, in charge of providing low-cost finance and

* I am grateful to Hans Böckler Foundation for the financial support to write this paper.

18-19 June 2015, Economics and Finance**

maintaining the stability of the exchange rate. Stabilising the inflation rate would be given to wage policy. Fiscal policy's main tasks would be to correct aggregate demand shocks and reduce income inequality.

Introduction

This paper attempts to provide a contribution to the empirical literature about macroeconomic policy regimes (MPRs) analysing the economic development of Poland using the concept of MPR. According to this concept, both policies and institutions play an important role in explaining the economic development of a country. A MPR consists of policies (foreign economic policy, industrial policy, wage policy, monetary policy and fiscal policy), the financial system and the institutional frameworks in which the economies are embedded.¹ In emerging countries, which have been the primary focus of my latest work, six elements of a MPR can be identified: foreign economic policy, industrial policy, the financial system, wage policy, monetary policy and fiscal policy. The development of these elements will be examined within the context of the given institutional framework and the most important institutional changes which took place from the mid 1990s onwards. The functionality of the development of the MPR elements in Poland will be analysed using a normative model set in Section 3.

I chose Poland as a case study for the reason that it is firstly, the single country, which managed to avoid a financial crisis and sliding into a recession amidst the latest EU financial, economic and sovereign-debt crises. Furthermore, it is a country which has maintained a certain level of capital controls albeit it joined both the OECD and the EU. The third reason is that Poland is comparatively to the other Central Eastern European Countries (CEECs),² a large economy. Fourthly, both during the times of the Soviet Union and today, Poland has maintained a relatively large industrial sector.

In a nutshell, the analysis of the functionality of the development of MPR in Poland since the mid 1990s shows that owing to the significantly large manufacturing sector, Poland has had an improvement of the trade balance, but not the current account balance *per se*. The country seems to

¹ This definition of a MPR for an emerging economy draws on Kazandziska (2013). Herr&Kazandziska (2011), as well as Heine, et al. (2006) define MPR for industrial countries.

² Here under CEECs we mean the ten countries, which entered the EU in 2004 and 2007: Bulgaria, Czech Republic, Estonia, Hungary, Latvia, Lithuania, Poland, Romania, Slovakia and Slovenia.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

lack behind the EU level with regards to the production and exports of high value-added products. As a result of the financial system regulations and the maintenance of a certain level of capital controls the financial system was able to escape a major banking or financial crisis. Monetary policy was periodically able to provide a low-cost finance to the financial system. The central bank seemed to have been torn between its goals of maintaining price level stability and keeping the exchange rate stable using the interest rate as a main instrument. The conduct of wage policy in Poland was restricted due to the very limited power of trade unions and employers' associations, particularly at the sectoral or national level and the limited efficacy of the alternative instruments of wage coordination (extension of collective agreements or minimum wages), which resulted in low collective bargaining coverage and a low level of wage coordination. Fiscal policy often showed stop-and-go development. After adopting the Euro Plus Pact in 2011, the fiscal policy turned particularly restrictive in the period 2012-2013, which has had a negative impact on the economic growth. The high income inequality of disposable income shows that the redistributive policies of the government had a limited success in favouring income distribution towards low-income and low-wealth households.

In section 2 the focus will be put on the methodology used in this paper. Section 3 sketches the outline of a normative model of a MPR on the basis of which the functionality of the MPR development in Poland will be assessed. In the section that follows a separate analysis of the MPR elopements will be provided. The last section concludes.

Notes on the methodology

To start with, the concept of MPR is of a qualitative nature. As we shall also see below, this concept is also of highly complex and comprehensive nature, using both economic policies and institutions in the process of explaining the economic development of a country. Furthermore, due to the unavailability of long-run, continuous and cross-country comparable data for certain variables, there are limitations to the conduct of a reasonable econometric analysis. Hence, the methodology of this paper includes a brief review of the primary literature related to MPRs.

Moreover, a Tinbergen type of approach is used, whereby I identify objectives, instruments and strategies for all the individual elements of MPR. The analysis of the fulfilment of the assigned objectives and the use of in-

18-19 June 2015, Economics and Finance**

struments and strategies entails the use of specific indicators. Hereby, statistical data analysis and use of descriptive statistics is conducted.

The elements together with their assigned objectives, instruments and strategies form one normative model, on the basis of which the functionality of the MPR in Poland will be evaluated. The development of a MPR element is considered functional if the elements of MPR met the objective(s) assigned and if they reached the goal using the specific instruments and the strategy allocated to them. Due to limited space, I will concentrate mostly on the first criterion – the achievement of the goals assigned for each element of MPR.

The model proposed in this paper draws significantly on Kazandziska 2013, where it has been more comprehensively elaborated. Kazandziska 2013 puts a focus on the development of MPR in the Latvian economy. We have to be well aware of the many peculiarities in the economic, political or social development in the individual countries. However, due to the significant amount of similarities among the Central Eastern European countries (CEECs), the normative model for an emerging country developed in Kazandziska (2013) can be also applied to the Polish economy. Nonetheless, the country-related specific features and developments, which have played an important role into forming the MPR in Poland, will naturally not be disregarded.

Outline of the model

As described earlier in the text, MPR is defined as a set of policies (foreign economic policy, industrial policy, wage policy, monetary policy and fiscal policy), the financial system and institutions in which the economies are embedded (Kazandziska, 2013). Applied to emerging countries, we can identify the following elements of a MPR: foreign economic policy, industrial policy, the financial system, wage policy, monetary policy and fiscal policy. The functionality of each of these elements will be analysed on the basis of the fulfilment of the objective(s) assigned to it. Furthermore, the major institutional changes, which have had a significant impact on the development of the particular elements, will also be addressed.

In emerging countries as open economies, foreign economic policy and industrial policy will be assigned quite important objectives. The former will be given the tasks of reducing the current account deficits and achiev-

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

ing a balanced current account, and reducing the capital flow volatility.³ The reduction in current account deficit is in the long-run to be achieved through exports of high-tech, high value-added products, which will improve the terms of trade.⁴

Here comes industrial policy to the fore by supporting the revival of the manufacturing sector, particularly the production of high value-added products, which in the long-run can improve the terms of trade and the current account. The government spending on research and development (R&D) and various forms of state-aid can be used to support certain sectors/firms, which are involved in the production and/or exports of high-end products, which could increase the income elasticity of exports.

The financial system needs to support this growth strategy based on external balance, by providing a sufficient finance to the manufacturing sector, particularly to the targeted industries/firms (which, produce and/or export high value-added products). Being that the subject of our analysis are emerging countries, whereby banks play a dominant role in the provision of finance, supply of a sufficient amount of finance in the form of credit will be of a paramount importance. The financial system also needs to secure the stability of the financial sector through diverse regulations diverting credit away from the speculative sectors (real-estate, construction sector) especially in times of an asset-price bubble.

Wage policy's main task would be to provide a stable wage anchor and thus, help secure the stability of the inflation rate. A necessary precondition for a functional wage policy is wage coordination within and among sectors, which can be achieved through sectoral or national wage bargaining, supported by extension of collective agreements and minimum wages.

³ Current account deficits lead to drainage of foreign exchange reserves and, particularly in emerging countries they can reduce the credibility of the domestic currency and monetary policy. However, export-led growth strategies to achieve current account surpluses are only possible for individual countries (see for instance, Onaran&Galani, 2012 for more elaboration). Reduced capital volatility serves the aim of preventing financial and currency crises, as well as creating conditions for a more stable investment by the private sector.

⁴ Devaluation can only under certain conditions and mostly in the short- to medium-run, bring positive results (some of the conditions are: low/no dollarization, low level of external debt, stable wage anchor, and low exchange-rate-pass-through, so that the currency can devalue in real terms). Thirlwall (1979, 2013), McCombie&Thirlwall (1999) added also that the devaluation would have to be continuous so that the positive net effects are not only short-lasting. However, if nominal wages continuously lag behind nominal devaluation and the exchange-rate-pass-through is high, the wages of the workers in real terms will erode, which is politically and socially unsustainable.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

Monetary policy would be in charge of providing low-cost finance to the financial system,⁵ securing the stability of the latter and, especially important in emerging countries, providing a stable nominal exchange rate anchor.⁶ Providing low-cost finance, mostly provided through low real interest rates is also supportive for the stabilisation of interest payments on the public debt and thus opens more room for manoeuvre for fiscal policy.

Two major objectives will be assigned to fiscal policy: reducing shocks to aggregate demand (mostly by government spending, because of its high fiscal multiplier) and reducing income inequality (through tax and transfer policies)⁷.

It is noteworthy to mention that all the elements need to be coordinated for the most optimal functioning of one MPR.

Macroeconomic policy regime of Poland

In the next section we are going to briefly analyse the main drivers of economic growth in Poland, followed by the examination of the individual elements of MPR and the functionality of their development. Due to data unavailability for the earlier years, the period under observation starts in 1995 and ends with 2013.

Economic development

After declining at a rate of 7 per cent in 1991, the Polish economy recovered a year later, experiencing a positive growth of 2.5 per cent. Until the late 1990s, the economy grew on average at a rate of about 6 per cent (Eurostat 2015). The growth during this period was predominantly driven by the domestic demand. Both private consumption and investment have had a significant contribution to the economic growth. However, government consumption seems to also have had an important impact (Table 4.1).

⁵ Low-cost finance is to be mainly provided through low real interest rates.

⁶ Exchange rate regime in the form of fixed (or close to fixed) exchange rate is commendable (Kazandziska, 2013, Priewe&Herr, 2005).

⁷ Income redistribution towards low-income and low-wealth households can potentially stimulate consumption and thus, economic growth, as these households have a relatively high marginal propensity to consume (see for instance, Hein&Truger, 2014).

Building comprehensive welfare systems is also an important goal of fiscal policy. However, due to space constraints, we are only going to focus on the two other objectives of fiscal policy.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

In 1998 the economy showed the first signs of a slowdown as a consequence of the Asian and later on, the Russian financial crisis. The economy grew at a much lower pace amidst the European and world economic slowdown. During the years of economic downturn, growth remained positively largely due to private consumption expenditure and net exports. Smaller, but positive contribution was made by government consumption. From 2003 until 2007 the economy had a relatively stable growth. From 2008 until 2009, the Polish economy felt some of the negative effects of the European and world financial and economic crisis. But, the economy managed to avoid sliding into a recession owing largely to the positive growth of government consumption and to a lesser extent, to the private consumption. In 2009, net exports improved as a result of the currency devaluation and the undervaluation strategy that followed. In 2011, the government resorted to a pro-cyclical fiscal policy which had a contractionary effect on the economy in 2012 and 2013.

Table 1 Contributions of the components of aggregate demand to GDP (growth rate, per cent)

	1995-1999	2000-2003	2004-2007	2008-2013
Private consumption	3.8	1.6	2.7	1.7
Gross fixed capital formation	2.5	-0.6	2.1	0.5
Government consumption	0.6	0.5	0.8	0.4
Net exports	-1.6	1.3	-0.8	0.9

Foreign economic policy

Foreign economic policy in Poland has been shaped by the Polish entry in the OECD in 1995 and the EU accession in 2004. These events had as a consequence institutional changes with a profound impact on the development of the MPR in Poland, such as liberalisation of the trade and capital account. With regards to the latter, Poland followed a path of a gradual deregulation (Sadowska-Cieślak, 2003). The Foreign Exchange Law passed in 1998, stipulated that non-residents were allowed to purchase domestic short-term securities and derivatives only with a foreign exchange permit granted by the National Bank of Poland (Janc&Marszalek, 2014). Poland kept most of the restrictions, particularly on short-term capital flows until 2002. In 2002 the government adopted a new law, according to which the

majority of the restrictions on capital flows to and from the rest of the EU and OECD countries were lifted. In 2007 also many barriers on capital in- and outflows related to a securities trade to and from third countries were also eliminated (Janc&Marszalek, 2014).

Albeit the Polish government has kept a certain level of capital controls even until today, the size of the net capital flows has been quite significant, which had repercussions on the development of the current account.⁸

Figure 1 Development of the current account, trade and income balance in Poland (net, year-on-year percentage change), 1995-2013

Source: National Bank of Poland, author's calculations.

The first objective of foreign economic policy is to reduce the current account deficits and achieve a balanced current account in the medium- to long-run. The current account in Poland was in deficit during the whole period of analysis, from 1995 until 2013 (Figure 4.1). From the mid until the late 1990s, the current account deficits increased mainly due to the rise in the trade deficits. From 2000 until 2005 the trade deficit was reduced, which led to a reduction of the current account deficits until 2003. In the period thereafter the deficit of the income account started rising as a consequence of the primary income deficits. From 2006 until 2008 we can observe an increase of the trade and current account deficits. The period that

⁸ The Chinn-Ito index of capital account liberalisation equalled to 0.06 in 2011 (the latest data available), whereas the index in the EU-countries on average had a value of 2.44, which is close to the highest value of 2.48 (Chinn&Ito 2006, 2001).

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

follows is marked by a reduction of the trade deficits (mostly due to a faster decline of imports compared to exports) and an improvement of the current account balance. However, in all these years the decline of the trade deficits was not sufficient to compensate for the increase of the deficit in the income account, which resulted in current account deficits. One important point to make here is that the decline of the trade deficits was highly as a result of the fall of imports below exports. Furthermore, the export structure has not been advantageous (the share of high-technology exports in total manufactured products was only less than 4 per cent on average in Poland, while in the EU the former equalled to 17 per cent) (author's calculation based on World Bank 2015).

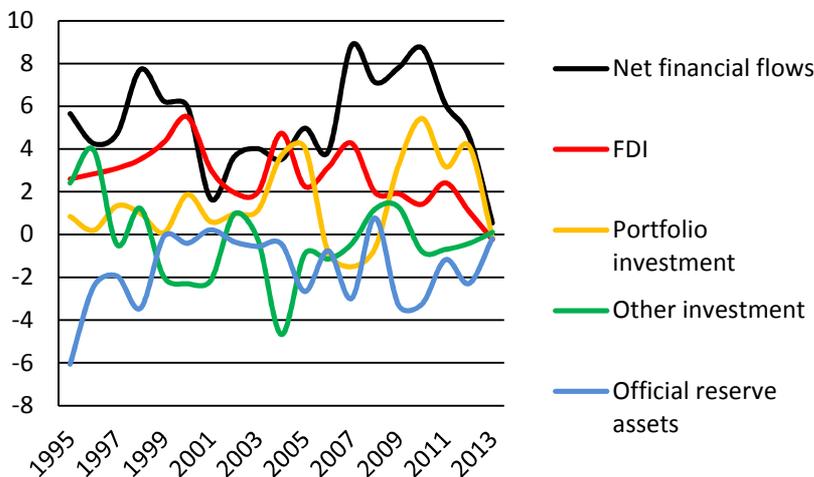

Hence, we can argue that the first objective of foreign economic policy to reduce current account deficit and achieve a balanced current account, was not achieved.

Reducing the capital flow volatility is the second task assigned to foreign economic policy. Figure 4.2 shows that the volatility of capital flows in Poland increased after the mid 1990s. Net capital flows increased particularly until the Russian financial crisis in 1998. The latter accompanied by the downturn in the other European countries in 2000/2001 caused a withdrawal of capital. The period until 2006 was marked by a relative stability. However, in 2007 and in 2009/2010 a very strong rise in net capital inflows can be spotted due to the fact that all member countries of the EU experienced a recession and Poland was the only country that managed to escape entering a recessionary scenario. Thus, international investors saw a very attractive opportunity in investing in Polish assets. Yet, from 2011 onwards, there has been a strong decline in net capital inflows.

If we take the standard deviation as a measure of capital flow volatility, we can see that Poland had a slightly higher volatility than the countries in the EU.⁹ Until 2007 international capital entered mostly in the form of FDI. The reason for this was that long-term flows were liberalised before short-term capital flows (IMF 2008). In 2007 most of the restrictions on capital in- and outflows were lifted, which led to a rise in portfolio flows. From 2008 onwards FDI lost some of its momentum and portfolio flows picked up. In 2013 both net FDI and portfolio flows declined.

⁹ The standard deviation of the net capital flows for the period 1995-2013 in Poland amounted to 2.2, while the former had a value of 2.0 in EU-15 (unweighted average, author's calculation based on Eurostat 2015).

Figure 2. Development of net capital flows and their composition in Poland (per cent of GDP, year-on-year percentage change), 1995-2013

Source: Bank of Poland, author's calculation

Hence, we can conclude that, firstly, foreign economic policy only intermittently was able to reduce the current account deficits, but over the years, current account balance was not achieved. Secondly, a certain stability of capital flows was achieved until about 2006; however, in the period thereafter as net portfolio flows strongly increased, a higher volatility of net capital flows is to be observed.

In the next section, a due attention will be paid to the sectoral composition of the economy and the functionality of industrial policy in restructuring the economy in order to improve the terms of trade and the current account.

Industrial policy

There are various uses and definitions of the concept industrial policy. In this paper industrial policy is used to signify a policy aimed at particular industries/firms that could raise the economic welfare of the whole economy (Chang, 1994, 2006, 2010). In the EU-terminology, it is the so-called 'vertical' or 'sector-specific' policy.

In Poland industrial policy was highly connected to the privatisation process. This has been the first important institutional change that shaped

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

industrial policy in Poland. It was aimed at recovering some very crucial sectors, which had financial difficulties and at privatising or transforming the enterprises, which operated in sectors, which had a potential for high profitability and expansion in future (like, pharmaceuticals, chemical industry, metal industry, telecommunications and the energy sector) (Błaszczuk et al., 1997). The success of these programmes was due to a lack of resources and a clear strategy quite limited. Only in the National Development Programme for 2016-2020 the government for the first time emphasized the need to support the high-technology sectors (Council of Ministers of the Republic of Poland, 2012).

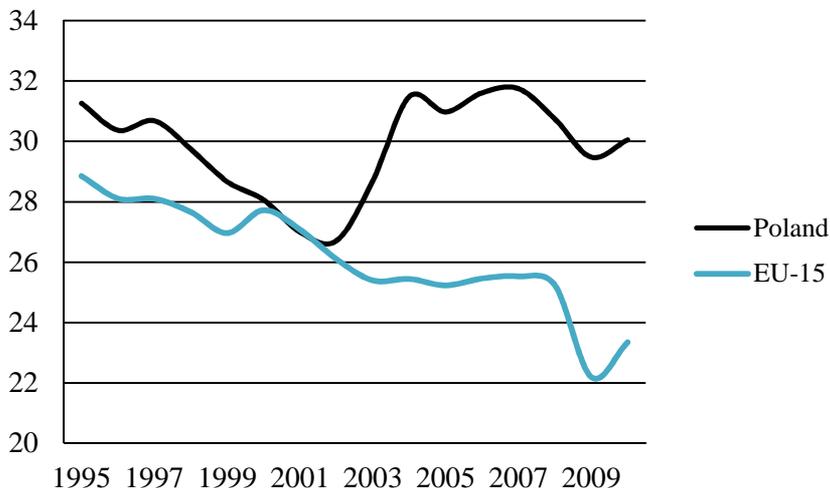

A second important institutional change was the accession of Poland in the EU. The EU membership entailed a restriction on the part of ‘vertical’ or ‘sector-specific’ industrial policy, as it is considered harmful for the ‘healthy’ competition among enterprises. Under the EU-law emphasis is put on the so-called ‘horizontal’ policies, which are universal policies, not favouring any particular industries or firms (Lech, 2007).¹⁰ Thus, upon joining the EU, Poland had to adjust its industrial policy according to the EU guidelines.

Industrial policy in our model has one very important role: reviving the manufacturing sector. We are going to analyse the development of the manufacturing output-total output ratio, which is going to show us the share of this sector in the total economy. Similarly to other CEECs and to the EU countries, Poland also experienced a decline in this ratio in the second half of the 1990s (Figure 4.3). By the early 2000s the share of this sector in the total output increased but the rise was not very impressive. Only in 2004 was manufacturing able to reach the same level relative to total output, which it had in 1995. It stayed around this level until today. One more important point to make is that the share of the high-technology manufacturing sectors in the total output was lower in Poland than the EU-average.¹¹

¹⁰ Such ‘horizontal’ policies are supporting the development of SMEs, investment in R&D and training programmes and environmental protection.

¹¹ The share of high-technology manufacturing sectors in total output equalled to 3.9 per cent in Poland and to 5.4 per cent for the EU-countries for the period 2000-2010 (un-weighted average, author’s calculation based on Eurostat 2015).

Figure 3. Manufacturing sector output in Poland and EU (share of total output, per cent), 1995-2010

Source: Eurostat, author's calculation.

This section can be concluded by arguing that industrial policy was able to stop the declining trend of the manufacturing sector. Yet, the output of the latter recovered at a very low pace. In the conduct of industrial policy in the sense of 'vertical' policy, the Polish government was highly constrained by the EU-Treaties beginning from 2004 onwards. In its recent reports, the government emphasizes the role of high-technology sectors for the economic development of the country. But, targeting of specific industries/companies is not part of the agenda.

Financial system

With the adoption of the Act on the National Bank of Poland and the Banking Law in 1989, the foundations for the functioning of a two-tier banking system were laid. The financial system in Poland (similarly to the other CEECs and many emerging countries) is predominantly bank-based, whereby bank loans are the single most important source of finance for the firms.¹² Banks also own the largest share of assets in the financial system.¹³

¹² In 2010 over 50 per cent of the firms in the economy (excluding the financial and insurance sectors) used banks as a source of finance (Eurostat 2015).

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

The assets of the banking system in Poland are also predominantly foreign-owned.¹⁴

The main tasks of the financial system in the model presented in Section 3 are to provide a sufficient finance to the business sector and to maintain the stability of the financial system. The analysis of the fulfilment of the first task will encompass mostly the banking sector loans being that banks have been the most important providers of finance in Poland. The indicator we are going to look at is the corporate loans-GDP ratio.¹⁵ On a more general note, we can say that until 2006, the growth of total credit in the economy has not been very high (Figure 4.4). The reason for the relatively poor credit growth is the sluggish development of the corporate credit amidst the Russian and European crises in the period 1999-2001 and even a decline of the corporate sector credit in 2004-2005. In the period after 2007 corporate credit picked up, largely due to the elimination of most barriers to the capital flows and owing to the strong capital inflow. Yet, this growth was rather short-lived. In 2010 and 2011 as a result of the European financial and economic crisis corporate sector credit declined.¹⁶ During the latest economic downturn there has been a decline in demand in the side of the companies for loans. However, during the periods of rising economic growth when also the household credit increased (for instance, between 2002 and 2004), firms seem to have faced a financial constraint and a stronger credit rationing by the banking sector.¹⁷

On the other hand, the household sector credit-GDP ratio showed a trend of stable increase throughout the whole period (except in 2010, when it stagnated).

¹³ For instance, between 2005 and 2008, banks owned 75 per cent of the total assets in the financial system (EBRD, 2009, pp. 13).

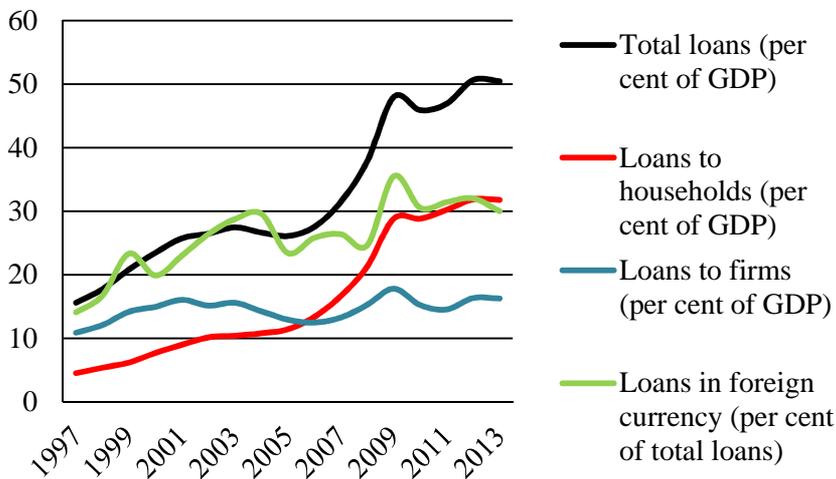

¹⁴ Between 2005 and 2008, 70 per cent of the total banking system assets (which includes the banking sector, stock market and bond market capitalisation) were foreign-owned (EBRD, 2009, pp. 13).

¹⁵ Corporate loans include both financial and non-financial corporation loans.

¹⁶ However, household credit relative to GDP seems to have grown over most of the years (except in 2010 and 2013).

¹⁷ In 2003 the share of firms, which perceived the access to finance to be the strongest obstacle to the firm's performance increased from 34.3 per cent in 2002 to 35.9 per cent in 2003 (World Bank's Enterprise Surveys data).

Figure 4 Development of loans per sector and loans in foreign currency in Poland (per cent), 1997-2013

Source: National Bank of Poland, author's calculation.

Maintaining financial system stability as the second task of this element of MPR will be assessed by analysing firstly, if there has been a banking crisis in the country. For this purpose, the banking crisis dummy from the Global Financial Development indicators database of the World Bank will be used.¹⁸ As this indicator had a value of zero in all the years, we can say that the financial system in Poland managed to keep away from a banking crisis. The share of foreign currency loans to the total loans will be the next indicator, which is going to show us the level of dollarization/euroisation in the country. In the case of Poland we can see that this ratio increased after 2004 (Figure 4.4). But, owing to the timely introduction of several financial system regulations, this ratio was contained at a level of around 30 per cent.

We can summarise this section with the arguments that firstly, the financial system met the objective of providing a sufficient finance to the business sector only partially. As to the objective of financial system stability, we can argue that the financial system has been able to achieve a relative stability owing to the various regulatory instruments.

¹⁸ Visit the website of the Global Financial Development indicators of the World Bank for more information (<http://data.worldbank.org/data-catalog/global-financial-development>). The banking crisis dummy can have a value of one or zero (if the country did or did not have a banking crisis, respectively).

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

Wage development/policy

We are going to begin this section by the argument that the conduct of wage policy has been restricted in Poland. There are several reasons for making this statement. First of all, wage bargaining, if at all, has been mostly conducted at a company-level (Visser, 2011). Very often due to the absence of trade-union representation, because of the conflict between a few trade-unions representing workers at the same company or the small size of the companies, collective bargaining even at a firm-level is absent and the managers often individually decide on the size of the workers' pay. The collective bargaining coverage still remains low relative to the other European countries.¹⁹ The membership in trade union and employers' associations has also been quite modest.²⁰ Sectoral or national wage negotiations are rare because of the very limited power and a lack of organisation of the social partners at a sectoral or national level. At the national level, social partners are essentially involved in the setting of the minimum wage within the Tripartite Commission on Social and Economic Affairs. Furthermore, from 1994 until 1994 the tripartite commission was also in charge of determining the target maximum increase of the average monthly wages in the public sector and in the private companies with more than 50 employees.²¹ The calculation of the wage increases took into account the projected GDP growth rate and the inflation rate. Although these target wage increases served only as guidelines for the companies in the private sector when negotiating the wage increases of their employees, the former were obligatory for the public sector (Wratny, 2006). Yet, wage coordination has remained at a low level in Poland (Visser 2011). The efficiency of the mini-

¹⁹ The collective bargaining coverage in 2010 was 29 per cent in Poland, while in the EU it was around 60 per cent (unweighted mean average, author's calculation based on Visser, 2011).

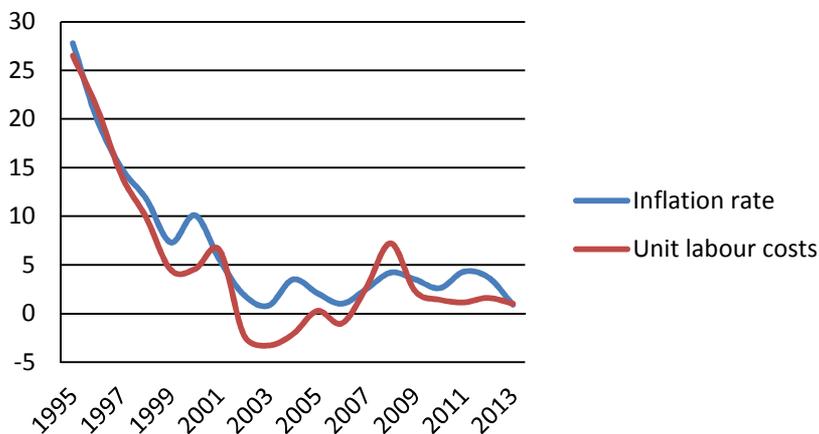

²⁰ Trade union density was 14 per cent in 2010. Employers' associations organised only about 20 per cent of all the firms in 2007 (Visser, 2011).

²¹ Act of 16 December 1994 (Journal of Laws 1995, No. 1, Item 2 and amendments) on negotiating system of entrepreneurs' average wage increases and Act of 23 December 1999 (Journal of Laws 1999, No. 110, Item 1255 and amendments) on creation of wages in the public sector. These acts replaced the wage control tax law (called *popiwiek*), according to which sanctions in the form of higher taxes were to be paid by companies, which paid higher wage increases for their employees than the officially allowed rates (Kabaj, 1998).

minimum wage policy and the extension of collective agreements have been also limited.²²

The most important task for wage policy is to maintain the stability of the inflation rate in the medium- to long-run. The first indicator we are going to look at is the inflation rate. In Poland we can observe a certain volatility of the inflation rate. Put into perspective, we can say that Poland had a higher volatility of the inflation rate compared to the EU countries.²³ There is a strong correlation between the development of the inflation rate and the unit labour costs, which is also confirmed in the case of Poland. Thus, we are going to analyse the development of unit labour costs next.

Figure 5 Inflation rate and the growth of unit labour costs in Poland (per cent), 1995-2013

Source: Eurostat 2015.

In the second half of the 1990s we can observe that the growth of the unit labour costs and the inflation rate slowed down (Figure 4.5). This was due to the narrowing down of the gap between the development of the nominal wages and productivity growth. From 2002 until 2006 the growth of

²² The minimum wage has been often used as a basis for the calculation of the wage increases particularly in companies, which have not been covered by collective agreements. However, minimum wages have not contributed to higher wage coordination within or among sectors (Du Caju et al., 2008).

²³ The value of the standard deviation for Poland was 7.2, the one for the EU-countries amounted to 0.6 for the period 1995-2013 (author's calculation based on EU Commission, 2015).

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

unit labour costs turned even negative because of the clear wage moderation policies (Eurostat 2015). The depreciation of the zloty and the increases in import prices helped prevent a deflationary development (Eurostat, 2015). In the following years all through 2010 nominal wage growth picked up beyond the increases in productivity, which stimulated a rise in inflation. From 2011 until 2013 nominal wages grew at a pace close to the productivity growth.

To summarise, wage policy first of all, not faced certain constraints in Poland. Secondly, and connected to the first argument, due to the uncoordinated wage increases, the development of the inflation rate was not stable. Some alternative instruments of wage policy, which serve the purpose of increasing the wage coordination, like, minimum wages or extension of collective agreements, have been put in use, but the effects have been rather limited.

Monetary policy

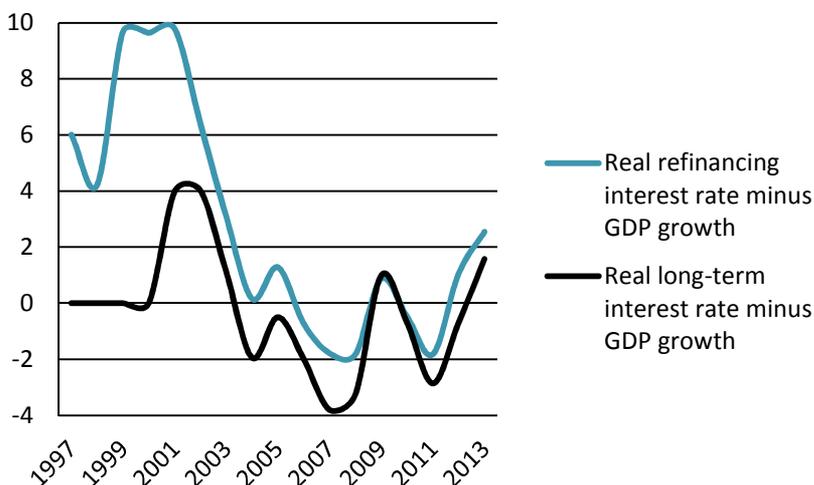

As also established in Section 3.4, the first major institutional change, which had a great impact on the financial system and the use of monetary policy, is the creation of the two-tier banking system in 1989. The second very important institutional change happened two years later, when the National Bank of Poland decided to abandon the fixed peg exchange rate regime and adopt the crawling peg instead. The reason for this decision was the shortage of foreign exchange reserves (Borowski, et al., 2003).

The surge in capital flows and the high costs of sterilisation led the central bank to switch to a crawling band in 1995 (Kokoszczynski, 2002). Chronologically speaking, the fourth important institutional change was the abandonment of monetary targeting as a monetary policy strategy of the central bank and the adoption of inflation targeting in 1998 (Kokoszczynski, 2002). The decision of the central bank to abandon the crawling band and let the currency float was the fifth important change taking place in 2000.

Three objectives have been assigned to monetary policy. The first task this policy is in charge with is ensuring the stability of the financial system. When we analysed the development of the financial system in Section 3.4, we could see that the institutions in charge of the financial system (the financial supervisory agencies, the government and the central bank) were able to relatively keep the financial system intact. Thus, we can argue that the first objective of monetary policy has been met.

The second objective of monetary policy is to provide sufficient low-cost finance to the banking sector. The indicators we are going to use, the real short-term interest rate minus GDP growth and the real long-term interest rate minus GDP growth, give an insight into the *ex-post* monetary policy stance and the availability of low-cost finance. Until 2003, the (short-term and long-term) interest rates were higher than the GDP growth, which means that expansionary policy was *ex-post* restrictive for real investment and economic growth (Figure 4.6). From 2004 until 2008, the both ratios were negative, which means that monetary policy was expansionary. This could be also argued for the period 2010-2012.

Figure 6. Real short- and long-term interest rate relative to GDP growth (year-on-year growth, percentage points), 1997-2013

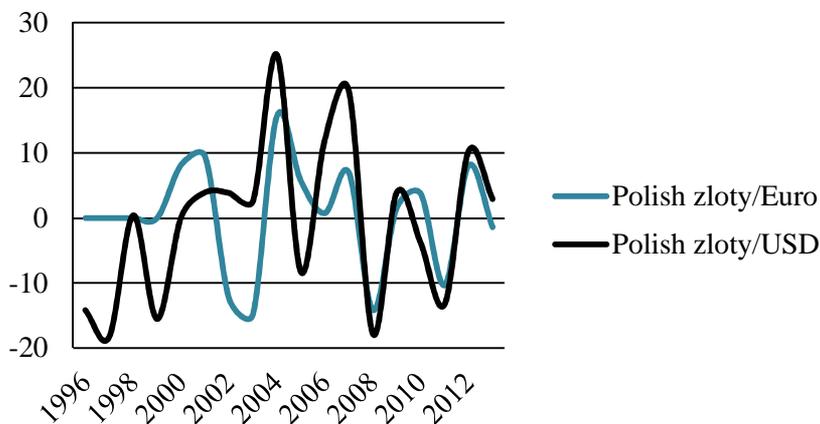

Source: Eurostat 2014, author's calculation.

The third objective of monetary policy is to preserve the stability of the exchange rate. Figure 4.7 shows that the exchange rate development between the zloty and the US Dollar, as well as between the zloty and the Euro has been relatively volatile. This can be argued both for the period prior and succeeding 2000, which is the year when the floating exchange rate regime was introduced. This means that the central bank's foreign exchange intervention was not successful enough so as to prevent fluctuations of the exchange rate, which then also had a negative impact on the competitiveness of the domestic companies.

**Proceedings of the 8th International Conference on Applied Economics
Contemporary Issues in Economy under the title Market or Government?
18-19 June 2015, Economics and Finance**

Figure 7. Exchange rate between the zloty, US dollar and the Euro (year-on-year percentage change), 1996-2013

Source: Eurostat 2015.

In a nutshell, we can conclude that monetary policy was able to protect the financial system from banking, currency or financial crises. Up to 2003, monetary policy was *ex-post* restrictive (real short- and long-term interest rates were above the rate of economic growth of the country). Only after 2004, was monetary policy conducive to investment and growth. This means that the second objective of monetary policy, providing a low-cost finance to the financial system, was only partially met. In spite of the various attempts of the central bank to stabilise the development of the nominal exchange rate through foreign exchange intervention, the fixed peg and the crawling peg could not be defended. The exchange rate development seems to have been relatively volatile in Poland.

Fiscal policy

The first major institutional change, which had a profound effect on the functioning of fiscal policy was the accession of Poland in the EU in 2004 and the requirements of the Maastricht Treaty to meet the fiscal criteria of keeping the budget deficit below the limit of 3 per cent of GDP and public debt-GDP ratio no higher than 60 per cent in order to be able to join the European Monetary Union. The second major institutional change was the adoption of the Euro Plus Pact in March 2011, with which the government committed to a policy of a budget consolidation.

The first major objective of fiscal policy is to reduce the aggregate demand shocks in the economy both in the short- and long-run. One indicator which can show us if the country has gone through a period of aggregate demand shock is the output gap. Between 1998 and 2002 we can observe a fall in the output gap, which signifies that the economy in this period was growing below potential output. During this time, the government attempted to reduce the budget deficits, which is also to be seen in the reduction of the structural (cyclically-adjusted) budget deficits. Hence, the government used pro-cyclically restrictive fiscal policy (Figure 4.8). Between 1999 and 2005, we can spot the stop-and-go fiscal policy, which postponed the economic recovery, although higher government spending was necessary to compensate for the increase in private sector saving (Figure 4.9). Only during the first two years of the recent economic slowdown in Poland (from 2008 until 2010), the government applied counter-cyclical expansionary fiscal policy. However, already in 2011, with the signature put on the Euro Plus Pact, the government deliberately resorted to budget consolidation amidst the economic slowdown.²⁴ The pro-cyclical fiscal policy stance in 2012-2013 did not only weaken the effects of the automatic stabilizers, but also had a negative impact on the economic growth.

The second objective of fiscal policy is to reduce the income inequality in the country. The Gini index of market income shows us the size of the income inequality before adjusting for taxes and transfer payments. The paper by Paci et al. (2004) shows that the Gini index of market income increased from 0.379 in 1994 to 0.407 in 2004. The OECD database shows that the income inequality, measured as pre-tax and transfer income inequality, was reduced between 2004 and 2009.²⁵ Yet, according to the same database, Poland had a higher pre-tax and transfer income inequality than the EU-average (OECD database).

²⁴ In the report from December 2014, the Polish government states that it undertook the following measures to consolidate the budget: it reduced the size of the discretionary public expenditures, it increased the retirement age for men and women, it eliminated the early retirement programmes, it froze the public sector wages and increased the value-added tax (Government of the Republic of Poland, 2014).

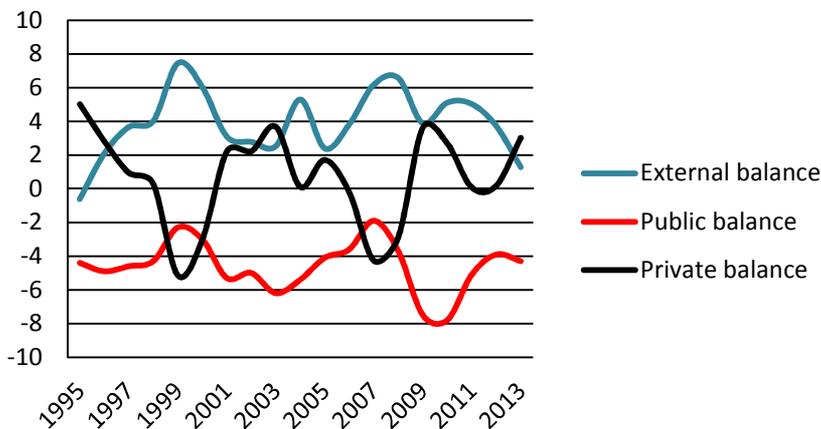

²⁵ According to OECD, in 2004 the Gini index of market income in Poland was 0.57, while in 2009 it amounted to 0.47 (OECD statistical database).

However, also if we look at the Gini index of disposable income, we can see that Poland has had higher income inequality than the EU-average (Eurostat, 2015). Income inequality measured as post-tax and transfer income inequality, increased between 1994 and 2004 from 0.308 to 0.317 (Paci et al., 2008). In the following years the income inequality was lowered owing to the increase in pension transfers.

Thus, we can derive the following conclusions regarding the functionality of fiscal policy. Firstly, although it had some counter-cyclical properties in single years, fiscal policy seems to have been pro-cyclical during most of the years of an economic slowdown. This has certainly delayed the economic recovery. Secondly, although reduced since 2004, income inequality, both measured as Gini index of market and disposable income has been higher in Poland than in the EU-members.

Conclusions

This paper had the aim to explore the economic development of Poland and to assess the functionality of the development of its macroeconomic policy regime using a normative model briefly sketched in Section 3. According to this model, foreign economic policy and industrial policy are given major tasks of restructuring the economy towards production and exports of high-technology, high value-added products, which would serve the purpose of improving the terms of trade and the current account in a structural and more sustainable way. Foreign economic policy is furthermore, given the significant task of maintaining a relatively low volatility of capital flows, which particularly in open economies like Poland, seems to be of a paramount importance for the stability of the financial system, the stability of the domestic currency and for preserving a more stable investment climate in the country. One of the main goals of the financial system is to provide a sufficient finance for the companies, particularly operating in the targeted high-technology sectors. The second major task of this MPR element is to protect the financial system from major disturbances and maintain its stability. Providing a wage anchor and thus, maintaining the stability of the inflation rate is assigned to the wage policy. Assuming that the wage policy was able to stabilise the inflation rate and that the monetary policy was successful in providing a nominal exchange rate anchor, the stability of the real exchange rate development and thus, the competitiveness of the domestic companies can also be sustained. Caring for the financial system as well as provision of low-cost finance for the financial system by relatively low real interest rate policy stability are also tasks of monetary

policy. Fiscal policy has been assigned two major tasks: combating aggregate demand shocks and reducing income inequality.

The case of Poland shows that:

1. There was a tendency of rather stable net capital flows until 2006. However, after most of the capital flow restrictions were eliminated, portfolio flows became more attractive and with that capital flow volatility increased. Thus, the task of foreign economic policy in maintaining the capital flow stability was relatively better fulfilled in the years preceding 2006, compared to the years thereafter.
2. Foreign economic policy was only occasionally able to reduce the current account deficits owing to the reductions in the trade deficits. However, the reduction of current account deficits did not occur due to structural improvements in the terms of trade, but mostly due to devaluation or as a result of a decline of imports in the periods of economic downturn. Throughout the years, income account deficits have been accumulating, which necessitated even bigger efforts to achieve a balanced current account.
3. Industrial policy did not seem to play an active role in the process of restructuring the economy towards production and exports of high value-added products. In the 1990s, the former was mainly concentrated in the area of privatisation and transformation of the large public-owned companies and banks. After 2004, the EU-accession seems to have played a crucial role in restricting industrial policy in the sense of 'vertical' or 'sectoral' policy.
4. In most of the years was the financial system able to provide the needed amount of finance. However, during the years succeeding the Russian financial crisis (from 2000 until 2005), there seems to have been a higher credit rationing towards firms, while the households were still able to receive the loans needed.²⁶
5. Owing to the various and very importantly, pre-emptive regulatory measures, the financial system was able to prevent the occurrence of asset-price bubbles, prevent capital flight during the economic downturns and thus, relatively maintain the financial system stability.
6. Monetary policy supported the financial system in securing its stability. But, with regards to providing low-cost finance to the financial system, monetary policy until 2003 was restrictive. Real interest rates were

²⁶ We do not mean here that there has not been any credit rationing towards households. But, households, which met the prevailing standards of creditworthiness, were most likely to receive a loan (compared to the firms).

higher than the GDP growth rate, which speaks of a failure of the central bank to provide a low-cost finance during these years. After 2004, monetary policy turned expansionary. The reason for this development is the attempt of the central bank to meet several goals with one instrument: the nominal short-run interest rate: fighting inflation, combating asset-price increase, while following an exchange rate peg and monetary targeting (and later on inflation targeting) as a strategy.

7. The central bank was not able to secure a more stable development of the exchange rate because of the shortage of foreign exchange reserves and a relatively open capital account.
8. Decentralised wage bargaining, weak trade unions and employers' associations and low collective bargaining coverage (because of the limited impact of the collective agreement extension mechanisms and of the minimum wage) disabled the conduct of a functional wage policy in Poland. Wage policy was not able to provide a stable wage anchor and thus, to prevent a volatility of the inflation rate.
9. Fiscal policy was often pro-cyclical. Especially during the economic downturns of 2000/2001 and 2012/2013, the government decided to consolidate the budget and cut public expenditure, which postponed the economic recovery.
10. Income redistribution policies as a part of fiscal policy were able to reduce income inequality; however, the effects of these policies seem to be less impressive than in the EU-countries.

Hopefully, this analysis of the MPR development in Poland is going to stimulate further theoretical modelling of MPR of emerging countries, as well as empirical research of the development of MPR in other CEECs or other emerging countries.
